Abstract Oxidized HDL (ox-HDL), unlike native HDL that exerts antiatherogenic effects, plays a proatherogenic role. However, the underlying mechanisms are not completely understood. This study was designed to explore the inducive effect of ox-HDL on endoplasmic reticulum (ER) stress-CCAAT-enhancer-binding protein homologous protein (CHOP)-mediated macrophage apoptosis and its upstream mechanisms. Our results showed that ox-HDL could be ingested by macrophages, causing intracellular lipid accumulation. As with tunicamycin (an ER stress inducer), ox-HDL induced macrophage apoptosis with concomitant activation of ER stress pathway, including nuclear translocation of activating transcription factor 6, phosphorylation of protein kinase-like ER stress pathway, including nuclear translocation of activating transcription factor 6, phosphorylation of protein kinase-like ER kinase and eukaryotic translation initiation factor 2α, and upregulation of glucose-regulated protein 78 and CHOP, which were inhibited by 4-phenylbutyric acid (PBA, an ER stress inhibitor) and CHOP gene silencing. Additionally, diphenyleneiodonium (DPI, an oxidative stress inhibitor), probucol (a reactive oxygen species scavenger), and toll-like receptor 4 (TLR4) silencing reduced ox-HDL-induced macrophage apoptosis, oxidative stress, and CHOP upregulation. Moreover, HDL isolated from patients with metabolic syndrome induced macrophage apoptosis, oxidative stress, and CHOP upregulation, which were blocked by PBA and DPI.‡ These data indicate that ox-HDL may activate ER stress-CHOP-induced apoptotic pathway in macrophages via enhanced oxidative stress and that this pathway may be mediated by TLR4.—Yao, S., H. Tian, L. Zhao, J. Li, L. Yang, F. Yue, Y. Li, P. Jiao, N. Yang, Y. Wang, X. Zhang, and S. Qin. Oxidized high density lipoprotein induces macrophage apoptosis via toll-like receptor 4-dependent CHOP pathway. J. Lipid Res. 2017. 58: 164–177.

Supplementary key words endoplasmic reticulum stress • CCAAT-enhancer-binding protein homologous protein • atherosclerosis • oxidative stress

Atherosclerosis, one of the prime causes of heart attack and stroke, has been well known as a lipid-driven inflammatory disease characterized by macrophage accumulation in subendothelial space. Apoptosis of macrophage-derived foam cells, especially in advanced atherosclerotic lesions where phagocytic clearance of dead and dying cells is defective, results in acellular necrotic lesions that are prone to plaque rupture and thrombosis formation, leading to the majority of acute vascular events (1). Thus, deeper understanding of the mechanisms of macrophage apoptosis may pave the way for developing novel therapeutic strategies to effectively prevent atherosclerotic plaque rupture and subsequent clinical complications (2). Oxidized LDL (ox-LDL) has been recognized as a major inducer, promoting foam cell formation and apoptosis in macrophages (3). In contrast, HDL exerts antiatherogenic functions such as promoting reverse cholesterol transport, suppressing inflammation, inhibiting LDL oxidation, and increasing endothelial nitric oxide production (4). However, accumulating evidence suggests that HDL, like LDL, is also susceptible to oxidative modification. Oxidized HDL contains a supplement.

Abbreviations: ATF6, activating transcription factor 6; CETP, cholesterol ester transfer protein; CHOP, CCAAT-enhancer-binding protein homologous protein; DAPI, 4', 6-diamidino-2-phenylindole; DCF, 2',7'- dichlorofluorescein; DCFH-DA, 2',7'-dichlorofluorescin diacetate; DPI, diphenyleneiodonium; ER, endoplasmic reticulum; GRP78, glucose regulated proteins 78; LDH, lactate dehydrogenase; MDA, malondialdehyde; MS, metabolic syndrome; MTT, 3-(4,5-dimethylthiazol-2-y-l)-2,5-diphenyl-2H-tetrazolium bromide; ox-HDL, oxidized HDL; ox-LDL, oxidized LDL; PBA, 4-phenylbutyric acid; p-eIF2α, phospho-eukaryotic translation initiation factor 2α; p-ERK, phospho-double-stranded RNA-activated protein kinase-like ER kinase; ROS, reactive oxygen species; siRNA, small interfering RNA; SOD, superoxide dismutase; TLR4, toll-like receptor 4; TM, tunicamycin; TUNEL, terminal deoxynucleotidyl transferase-mediated dUTP nick end-labeling.

(ox-HDL) loses the antiatherogenic functions of native HDL (5–7) and exerts effects instead by inducing proliferation and migration of vascular smooth muscle cells (8), promoting platelet activation (9), and causing apoptosis in endothelial cells (10). Ox-HDL has been detected in atherosclerotic plaques (11). It has been reported that ox-HDL exerts a cytotoxic effect on macrophages and accelerates atherosclerosis progression (12, 13). However, the precise underlying mechanisms are poorly understood.

Prolonged or severe endoplasmic reticulum (ER) stress is one major cause of apoptosis, in which CCAAT-enhancer-binding protein homologous protein (CHOP) is a specific proapoptotic molecule (14). CHOP can mediate macrophage apoptosis and contribute to the instability of atherosclerotic plaques (15–17). We have previously shown that ox-LDL can induce macrophage apoptosis by upregulating CHOP expression (18, 19). Here, we investigated the potential role of the ER stress-CHOP pathway in ox-HDL-induced macrophage apoptosis. We found that ox-HDL prepared in vitro and HDL isolated from patients with metabolic syndrome (MS) activated the ER stress-CHOP-mediated apoptotic pathway in macrophages, which could be blocked by oxidative stress inhibitors, toll-like receptor 4 (TLR4)-specific small interfering RNA (siRNA), and TLR4 antibody.

**MATERIALS AND METHODS**

**Reagents**

Tunicamycin (TM), 4-phenylbutyric acid (PBA), diphenyleneiodonium (DPI), probucol, Oil Red O, antibody against β-actin, siRNA against TLR4, and CHOP were purchased from Sigma (St. Louis, MO). DMEM and FBS were obtained from Gibco (Rockville, MD). Dil-ox-HDL and Dil-ox-LDL were from Xieheng Biotech (Beijing, China). RIPA lysis buffer and 3-(4,5-dimeth-

ylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) were purchased from Solarbio (Beijing, China). RIPA lysis buffer and 3-(4,5-dimeth-

Ox-HDL induces macrophage apoptosis via TLR4-dependent CHOP 165

oxidative stress inhibitors, toll-like receptor 4 (TLR4)-specific small interfering RNA (siRNA), and TLR4 antibody.
CHOP siRNAs are 5′-GUCAACCGGACAUCCGAAAdTdT-T′ (sense) and 5′-UUUGGAUGUGCCGUGGAUtildTdT-T′ (antisense).

Cell viability and LDH assay

The viability of the treated cells was measured with a MTT assay, as has been previously described (18), and expressed as the percentage of the optical density value of the treated cells in relation to that of the untreated control cells.

To further evaluate the extent of cell injury, we determined LDH activity in media by using an assay kit, according to the manufacturer’s instructions.

Cell apoptosis measurement

Cell apoptosis was measured by annexin V-FITC/propidium iodide (PI) double-staining assay and TUNEL assay, as has been reported in our previous work (19). In brief, the treated cells were harvested, washed with PBS, and then incubated in 500 µl binding buffer containing 5 µl annexin V-FITC and 5 µl PI for 15 min in the dark at room temperature. The apoptosis percentage was analyzed on a FACScan flow cytometer (Becton Dickinson, San Jose, CA). On the other hand, the treated cells on glass coverslips were washed with PBS, fixed with 4% paraformaldehyde, and then permeabilized with 0.1% Triton X-100. Thereafter, cells were incubated with TUNEL reaction mixture in the dark at 37°C for 1 h and with 4',6-diamidino-2-phenylindole (DAPI) for 5 min, respectively, and then observed using fluorescence microscopy (Olympus BX51, Tokyo, Japan). The cell apoptosis was expressed as the percentage of the number of TUNEL-positive cells to total cells.

Uptake of Dil-ox-HDL and Dil-ox-LDL

Cells were treated with 1,1′-dioctadecyl-3,3,3′,3′-tetramethylindolocarbocyanine perchlorate (Dil)-ox-HDL (12.5–200 mg/L) or Dil-ox-LDL (100 mg/L) for 6 h. Thereafter, the cells were washed with PBS, fixed with 4% paraformaldehyde, and counterstained with DAPI, and then the mean fluorescence intensity per cell was calculated using Image-Pro Plus software (version 6.0, Media Cybernetics, MD).

Intracellular lipid measurement

The accumulation of intracellular lipid was determined by using oil red O and Nile red staining. For oil red O staining, the lipoprotein-treated cells grown on coverslips were washed with PBS, fixed with 4% paraformaldehyde, and then permeabilized with 0.1% Triton X-100. Thereafter, cells were washed with PBS, fixed with 4% paraformaldehyde, and counterstained with DAPI, and then the mean fluorescence intensity per cell was calculated using Image-Pro Plus software (version 6.0, Media Cybernetics, MD).

Measurement of NAPDH oxidase activity

The activity of NAPDH oxidase in the treated cells was measured with a cytochrome C-chromometry detection kit according to the manufacturer’s instructions and expressed as nmol per min per mg protein.

Reactive oxygen species (ROS) measurement

DCHF-Da, a redox-sensitive dye that could be oxidized into 2',7'-dichlorofluorescin (DCF) by intracellular ROS, was used to detect intracellular ROS levels. The treated cells in 6-well plates were washed with PBS and then incubated with 10 µmol/L DCHF-Da in DMEM at 37°C for 20 min. After washing with PBS, the cells were harvested and suspended in PBS, and the mean fluorescence intensity was analyzed on a FACScan flow cytometer (Becton-Dickinson, San Jose, CA).

Statistical analysis

Data were expressed as the mean ± SD and analyzed by one-way ANOVA with the Student–Newmann–Keuls test for multiple comparisons.
Ox-HDL decreases cell viability and induces apoptosis in RAW264.7 cells

N-HDL did not exhibit significant cytotoxicity on RAW264.7 cells, whereas treatment with ox-HDL for 24 h markedly decreased cell viability and led to a dramatic elevation in LDH leakage in a dose-dependent manner (Fig. 1A, B). Both annexin V-FITC/PI double staining and TUNEL assay revealed that treatment with ox-HDL resulted in a significant increase in apoptosis with the peak at 100 mg/L concentration (Fig. 1C, D). There were similar data, including the decreased cell viability and elevated apoptosis in cells treated by TM, an ER stress inducer (Fig. 1A–D).

ER stress-CHOP pathway mediates macrophage apoptosis induced by ox-HDL

Because the ER stress-CHOP pathway plays an important role in macrophage apoptosis (15–17), we explored the effect of ox-HDL on CHOP and its two important upstream molecules, ATF6 and PERK. As is seen in Fig. 2A–C, as with TM, ox-HDL led to activation of an ER stress-CHOP pathway, as evidenced by nuclear translocation of ATF6, phosphorylation of PERK, and eIF2α, as well as upregulation of GRP78 and CHOP, both at the protein and mRNA levels. However, PBA, an ER stress inhibitor, significantly attenuated the ox-HDL-induced ER stress response and macrophage apoptosis (Fig. 2A, Fig. 3A, B).

To further confirm the contribution of CHOP to ox-HDL-induced macrophage apoptosis, we investigated whether silencing of CHOP could mitigate ox-HDL-induced apoptosis. As is indicated in Fig. 3C, D, siRNA specific for CHOP showed sufficient inhibition of CHOP expression and reduced ox-HDL-induced apoptosis by 41.2%. In addition, PERK is one of the key upstream factors that positively regulate CHOP expression during ER stress (18), so the effect of PERK inhibitor GSK2606414 on ox-HDL-induced macrophage apoptosis was also explored. As can be seen in supplemental Fig. S2, GSK2606414 not only attenuated the upregulation of p-PERK, p-eIF2α, and CHOP but also inhibited apoptosis in RAW264.7 cells induced by ox-HDL. These results suggest that the ER stress-CHOP pathway plays a crucial role in ox-HDL-induced macrophage apoptosis.

Ox-HDL induces intracellular lipid accumulation in RAW264.7 cells

Because the accumulation of intracellular lipid induced by ox-LDL is an important inducer of ER stress-CHOP-mediated macrophage apoptosis (18, 19, 24), we examined whether ox-HDL could be taken up by macrophages and induce foam cell formation. As is seen in Fig. 4A, Dil-ox-HDL was ingested by macrophages in a concentration-dependent manner but was less significant than was the uptake of Dil-ox-LDL. The Oil Red O staining (Fig. 4B) and Nile red staining (Fig. 4C) also indicated that lipid content in RAW264.7 cells was increased by ox-HDL in a dose-dependent manner, but was less significant than ox-LDL, suggesting that ox-HDL may induce the formation of macrophage-derived foam cells, but the effect is less potent than that of ox-LDL.

RESULTS

Alleviation of oxidative stress mitigates CHOP-mediated macrophage apoptosis induced by ox-HDL

Because the enhancement of oxidative stress induced by various stimuli acts as an inducer leading to ER stress and macrophage apoptosis (25), the alterations of oxidative stress in RAW264.7 cells treated with ox-HDL were investigated to identify causal factors for CHOP-mediated macrophage apoptosis. As is seen in Fig. 5A-C, preincubation with DPI (a selective inhibitor of NADPH oxidase) attenuated ox-HDL-induced macrophage injury as assessed by the elevated cell viability and the reduced LDH release and cell apoptosis. As with ox-LDL, ox-HDL significantly stimulated the oxidative stress response as determined by the increased NADPH oxidase activity, ROS production, and MDA content, as well as the decreased SOD activity, which were inhibited by DPI (Fig. 5D-G). In addition, pretreatment with DPI markedly inhibited ox-HDL upregulated GRP78 and CHOP expression both at the protein and mRNA levels (Fig. 5H, I). Similar results were obtained from ROS scavenger probucol-pretreated cells as assessed by the decreased apoptosis, generation of ROS and MDA, and the protein and mRNA expression of CHOP (supplemental Fig. S3), indicating that oxidative stress plays a key role in the ox-HDL-induced CHOP upregulation and macrophage apoptosis.

To further confirm the role of oxidative stress and CHOP pathway in ox-HDL-induced macrophage apoptosis, we also used mouse peritoneal macrophages in this study. As is seen in supplemental Fig. S4A-C, ox-HDL caused injury of mouse peritoneal macrophages, as assessed by the decreased cell viability and increased LDH leakage and apoptosis, which were inhibited by PBA and DPI. Additionally, ox-HDL induced the oxidative stress response, including the elevated NADPH oxidase activity, ROS production, and MDA content, as well as the decreased SOD activity, which were attenuated by DPI (supplemental Fig. S4D–G). Furthermore, ox-HDL upregulated CHOP expression, which was inhibited by PBA and DPI (supplemental Fig. S4H).

TLR4 is involved in ox-HDL-induced oxidative stress and CHOP-mediated macrophage apoptosis

TLR4 is one of the major transmembrane receptors for signaling transduction with the ability to modulate inflammation and immune-related genes and mediate the activation of macrophages and the formation of foam cells. Our previous work has proved that TLR4 mediates minimally modified low-density lipoprotein (mm-LDL)-induced ER stress in macrophages (26). So we investigated whether TLR4 could mediate ox-HDL-induced oxidative stress and CHOP-mediated macrophage apoptosis. As is shown in Fig. 6A, B, treatment with ox-HDL significantly upregulated TLR4 protein expression, whereas TLR4 silencing by TLR4

comparisons and Student’s t test for comparison between two groups using the SPSS 13.0 software for Windows. P values less than 0.05 were considered significant.
oxidative stress and CHOP-mediated macrophage apoptosis, we performed antibody neutralization tests using anti-TLR4 antibody, and similar results were obtained as assessed by the inhibitory effect of anti-TLR4 antibody (TLR4 Ab) on macrophage apoptosis, oxidative stress, and CHOP upregulation induced by ox-HDL (supplemental Fig. S5).

siRNA reduced ox-HDL-induced macrophage apoptosis and CHOP protein by 40.3% and 37.4%, respectively. In addition, TLR4 silencing also inhibited ox-HDL-induced oxidative stress response, as determined by the decreased NADPH oxidase activity, ROS production, and MDA content, as well as the increased SOD activity (Fig. 6C–F). To further confirm the role of TLR4 in ox-HDL-induced oxidative stress and CHOP-mediated macrophage apoptosis, we performed antibody neutralization tests using anti-TLR4 antibody, and similar results were obtained as assessed by the inhibitory effect of anti-TLR4 antibody (TLR4 Ab) on macrophage apoptosis, oxidative stress, and CHOP upregulation induced by ox-HDL (supplemental Fig. S5).

Fig. 1. Ox-HDL decreases cell viability and induces apoptosis in RAW264.7 cells. RAW264.7 cells were treated with the indicated concentration of ox-HDL, n-HDL (100 mg/l), or TM (4 mg/l) for 24 h. Cell viability (A) and LDH activity in media (B) were determined by MTT assay and a kit, respectively. C: Cell apoptosis was analyzed by flow cytometry, and the total apoptotic cells (early- and late-stage apoptosis) were represented by the right side of the panel (annexin V staining alone or together with PI). D: Cell apoptosis was measured by TUNEL assay and expressed as the percentage of the number of TUNEL-positive cells to total cells. Scale bar = 20 µm. Data are expressed as the mean ± SD of at least four independent experiments. *P < 0.05; **P < 0.01 versus control group.
Fig. 2. Ox-HDL induces activation of ER stress-CHOP pathway in RAW264.7 cells. A: Cells were pretreated with or without PBA (5 mmol/l) for 1 h, followed by incubation with ox-HDL (100 mg/l) or TM (4 mg/l) for 24 h, and then immunofluorescence experiments showed ATF6 stained with Cy3 (red) and nuclei visualized by DAPI (blue). Representative fluorescent images photographed by a fluorescence microscopy are shown. Scale bar = 20 μm. B, C: Cells were treated as described in Fig. 1, and then the protein and mRNA levels of ER stress markers were determined with Western blot and quantitative real-time PCR, respectively. Data are expressed as the mean ± SD of at least three independent experiments. *P < 0.05; **P < 0.01 versus control group.
Additionally, GSK2606414 not only attenuated the upregulation of p-PERK, p-eIF2α, and CHOP, but also inhibited apoptosis in RAW264.7 cells induced by HDL from MS patients (supplemental Fig. S6). To further elevate the value of the data from pooled samples of MS patients, we isolated HDL samples from individual plasma of MS patients and explored their effects on macrophage apoptosis and CHOP expression. As is shown in supplemental Fig. S7, similar results were obtained showing that treatment with HDL from MS patients led to macrophage apoptosis and CHOP upregulation, which were inhibited by PBA.

**DISCUSSION**

As a main feature of advanced atherosclerotic plaques, macrophage apoptosis promotes enlargement of the necrotic cores and plaque rupture and then leads to cardiovascular complications (1, 2). Ox-LDL plays a crucial role in macrophage-derived foam cell formation and apoptosis, but the role of ox-HDL in this process is not fully understood. In this study, our results showed for the first time that ox-HDL induced macrophage apoptosis by triggering HDL from MS patients induces oxidative stress and CHOP-mediated macrophage apoptosis

HDL is susceptible to oxidative modification under certain circumstances, such as in diabetes (27), metabolic syndrome, and cardiovascular diseases (28, 29). To further clarify the pathophysiologic significance of oxidative modification of HDL in clinical diseases, we isolated HDL from MS patients and investigated its effects on oxidative stress and CHOP-mediated apoptosis in RAW264.7 macrophages. The subject characteristics are presented in supplemental Table S1, and the content of oxidized phosphatidylcholines in HDL from MS patients was much higher than that in n-HDL, which was similar to ox-HDL prepared in vitro (supplemental Fig. S1). As is seen in Fig. 7A–C, treatment with HDL isolated from MS patients led to macrophage injury as assessed by the decreased cell viability and the elevated LDH leakage and apoptosis, which were blocked by PBA and DPI. In addition, HDL from MS patients induced oxidative stress response, including the increased NADPH oxidase activity, ROS production, and MDA content, as well as the decreased SOD activity (Fig. 7D–G), which were inhibited by DPI. Furthermore, HDL from MS patients upregulated expression of GRP78 and CHOP both at the protein and mRNA levels, which were attenuated by PBA and DPI (Fig. 7H, I). Additionally, GSK2606414 not only attenuated the upregulation of p-PERK, p-eIF2α, and CHOP, but also inhibited apoptosis in RAW264.7 cells induced by HDL from MS patients (supplemental Fig. S6). To further elevate the value of the data from pooled samples of MS patients, we isolated HDL samples from individual plasma of MS patients and explored their effects on macrophage apoptosis and CHOP expression. As is shown in supplemental Fig. S7, similar results were obtained showing that treatment with HDL from MS patients led to macrophage apoptosis and CHOP upregulation, which were inhibited by PBA.
TLR4-mediated oxidative stress and subsequently activating an ER stress-CHOP pathway, which was supported by the following observations. First, as with TM (an ER stress inducer), ox-HDL induced macrophage injury and apoptosis with concomitant activation of the ER stress pathway, including nuclear translocation of ATF6, phosphorylation of PERK and eIF2α, and upregulation of GRP78 and CHOP. Second, ox-HDL-induced apoptosis and activation of ER stress were inhibited by PBA (an ER stress inhibitor), CHOP gene silencing, and GSK2606414 (PERK inhibitor). Third, ox-HDL could be taken up by macrophages and cause lipid accumulation, but less effectively than could ox-LDL. Fourth, DPI (an oxidative stress inhibitor) and probucol (a ROS scavenger) reduced ox-HDL-induced macrophage

Fig. 4. Ox-HDL induces intracellular lipid accumulation in RAW264.7 cells. Ox-HDL induces macrophage apoptosis via TLR4-dependent CHOP

Oxidation was shown to significantly affect the biological properties of HDL from many aspects, including altering paraoxonase structure and decreasing lactonase activity (39), which might cause HDL dysfunction, as assessed by decreased antiatherogenic abilities or even becoming proatherogenic (6). For example, ox-HDL has been shown to halt cholesterol efflux from foam cells in comparison with native HDL (5). Moreover, ox-HDL can induce the proliferation and migration of vascular smooth muscle cells by promoting ROS production (8). In this study, we found apoptosis, oxidative stress, and upregulation of GRP78 and CHOP. Fifth, ox-HDL-induced macrophage apoptosis, oxidative stress, and CHOP upregulation were blocked by TLR4 siRNA and antibody. Sixth, HDL isolated from metabolic syndrome patients induced macrophage injury and apoptosis, oxidative stress, and upregulation of GRP78 and CHOP, which were blocked by PBA and DPI.

It is well known that HDL provides a protective role in cardiovascular diseases. The atheroprotective effects of HDL are mainly attributed to its ability to promote cholesterol efflux from lipid-laden extrahepatic cells, inhibit LDL oxidation and adhesion molecule expression, and protect endothelial cells (4). So elevating HDL level was recognized as a promising strategy to suppress atherosclerosis progression (30, 31). Cholesteryl ester transfer protein (CETP) inhibitors were considered to be promising and applicable for markedly raising HDL levels in animal models (32). However, the excess mortality and lack of significant effects to reduce carotid intima-media thickness and attenuate the risk of recurrent cardiovascular events using CETP inhibitors such as torcetrapib and dalcetrapib (33–35) result in a reconsideration, which is more important for the antiatherosclerotic functions of HDL, quantity or quality (36, 37). Thus, the effects of modification of HDL and changes in HDL composition on HDL properties and pathological significance drew great attention from researchers. As the most common type of modification under certain circumstances, such as in diabetes (27), metabolic syndrome, and cardiovascular diseases (28, 29, 38), oxidation was shown to significantly affect the biological properties of HDL from many aspects, including altering paraoxonase structure and decreasing lactonase activity (39), which might cause HDL dysfunction, as assessed by decreased antiatherogenic abilities or even becoming proatherogenic (6). For example, ox-HDL has been shown to halt cholesterol efflux from foam cells in comparison with native HDL (5). Moreover, ox-HDL induces ROS production and NF-κB activation and increases the expression of several proinflammatory genes, including tumor necrosis factor-α and cyclooxygenase-2 in endothelial cells and macrophages, which accelerate atherosclerosis development (10, 40, 41). Furthermore, ox-HDL can induce the proliferation and migration of vascular smooth muscle cells by promoting ROS production (8). In this study, we found...
Fig. 7. HDL from MS patients induces oxidative stress and CHOP-mediated macrophage apoptosis. RAW264.7 cells were pretreated with or without PBA (5 mmol/l) or DPI (5 µmol/l) for 1 h and then stimulated with HDL from MS patients (100 mg/l) or n-HDL (100 mg/l) for 24 h. that ox-HDL resulted in macrophage injury in a dose-dependent manner, as assessed by decreased cell viability and elevated LDH leakage and apoptosis.

Accumulating evidence indicates that activated ER stress in macrophages promotes the progression of early and advanced atherosclerotic lesions (42). Previous studies, including our own, have demonstrated that ER stress mediates the upregulation of scavenger receptors on macrophages, such as lectin-like oxidized LDL receptor-1 and CD36, and promotes foam cell formation (23, 43). On the other hand, prolonged and severe ER stress triggers pro-apoptotic signals in macrophages, which in turn result in the instability of advanced atherosclerotic plaques (14, 44). CHOP, a specific proapoptotic molecule regulated by ATF6 and PERK under ER stress, has been demonstrated to play a crucial role in macrophage apoptosis and the destabilization of advanced atherosclerotic lesions, whereas CHOP deficiency inhibits macrophage apoptosis and reduces plaque necrosis in advanced atherosclerotic plaques (15–17). Our previous studies have shown that ox-LDL induces CHOP-mediated macrophage apoptosis by activating ATF6 and PERK pathways, whereas D4F, an apolipoprotein A4 mimetic peptide, alleviates macrophage-derived foam cell apoptosis by inhibiting the ER stress-CHOP pathway (18, 19). In this study, we found that as with TM, ox-HDL not only induced macrophage injury and apoptosis but also activated an ER stress pathway, as assessed by the increased nuclear translocation of ATF6, phosphorylation of PERK, and eIF2α, as well as upregulation of GRP78 and CHOP. However, ox-HDL-induced apoptosis and activation of an ER stress-CHOP pathway were inhibited by PBA (an ER stress inhibitor), CHOP gene silencing, and GSK2606414 (PERK inhibitor). All these data suggest that activation of an ER stress-CHOP pathway may be involved in the inductive effect of ox-HDL on macrophage apoptosis.

The accumulation of intracellular lipid and oxidative stress are the important inducers of ER stress and macrophage apoptosis in vivo and in vitro (24, 25, 45). Our previous studies have proven that minimally modified LDL (mm-LDL) and ox-LDL can induce cholesterol accumulation in macrophages and subsequently stimulate ER stress (18, 19, 23, 26). In this work, we showed that ox-HDL could be taken up by macrophages and cause a significant increase in lipid accumulation but was less potent than was ox-LDL in promoting the macrophage-derived foam cell formation, suggesting that the effect of ox-HDL to induce macrophage-derived foam cell formation is much less than that of ox-LDL. ROS are recognized to be closely responsible for activation of ER stress and apoptosis. NADPH oxidases are the primary enzymes responsible for inducing ROS production in the vascular system. Studies of endothelial cells and aortic smooth muscle cells treated with ox-LDL and 7-ketocholesterol, respectively, have shown that NADPH oxidase mediates ER stress and apoptosis (46, 47), whereas probucol, a ROS scavenger, can protect human umbilical vein endothelial cells from injury induced by hypoxia/reoxygenation by inhibiting CHOP upregulation (48). In addition, oxidative stress also resulted from excessive decrease in activities of antioxidative enzymes, such as SOD (49). In the present study, ox-HDL led to a significant increase in NADPH oxidase activity and a decrease in the SOD activity, with concomitant increased production of ROS and MDA, which were mimetic to ox-LDL treatment. However, DPI, a selective inhibitor of NADPH oxidase, and probucol significantly inhibited oxidative stress, macrophage injury, and apoptosis, as well as upregulation of GRP78 and CHOP induced by ox-HDL, indicating that oxidative stress may mediate ox-HDL-induced activation of the ER stress-CHOP-associated apoptotic pathway in macrophages.

TLR4 has been implicated in oxidative stress and inflammation and related to cardiovascular diseases including atherosclerosis, hypertension, and diabetes (50). Inhibition of TLR4 attenuates vascular dysfunction and oxidative stress in diabetic rats (51). In addition to microbial pathogens, TLR4 recognizes modified lipoprotein, such as mm-LDL and ox-LDL, and promotes lipid accumulation in macrophages (52). However, TLR4 deficiency reduces foam cell accumulation and inhibits expression of interleukin-1α, vascular cell adhesion molecule 1, and monocyte chemotactant protein-1 in apolipoprotein E−/− mice (53). Our previous work has shown that TLR4 mediates cholesterol accumulation and subsequent activation of ER stress in macrophages induced by mm-LDL (26). The results in the present study showed that ox-HDL upregulated markedly TLR4 expression, whereas TLR4 silencing significantly alleviated macrophage apoptosis, oxidative stress, and CHOP upregulation induced by ox-HDL. Similar results were obtained in the TLR4 antibody-pretreated macrophages, further suggesting that TLR4 may mediate ox-HDL-induced oxidative stress and subsequent activation of a CHOP-induced apoptotic pathway in macrophages.

HDL is susceptible to structural modification, including oxidation and glycation under certain circumstances such as diabetes, MS, and atherosclerosis, and loses its antiatherogenic abilities or even becomes proatherogenic (27–29, 38). To further confirm the clinical significance of HDL modification, we explored the inductive effect of HDL isolated from MS patients on oxidative stress and the CHOP-mediated apoptotic pathway in macrophages. We showed that the content of oxidized phosphatidylcholines in HDL from MS patients was much higher than that in HDL from healthy subjects, which were similar to that of ox-HDL prepared in vitro. In addition, treatment with HDL from MS patients led to macrophage injury, as assessed by the decreased cell viability and elevated LDH leakage and apoptosis, induced oxidative stress response, and upregulated expression of GRP78 and CHOP, which were blocked by PBA and DPI. Furthermore, macrophage apoptosis and CHOP upregulation induced by HDL from MS patients were inhibited by PERK inhibitor GSK2606414.

In conclusion, the major findings of this study are that ox-HDL induced lipid accumulation and activated an ER stress-CHOP-induced apoptotic pathway in macrophages via an enhanced oxidative stress and that this pathway may be triggered by the binding of ox-HDL to TLR4, indicating that ox-HDL may also play a crucial, direct role in atherosclerotic pathogenesis. Therefore, we speculate that it may be possible to apply effective antioxidants to suppress HDL...
oxidation and improve HDL quality in patients with atherosclerotic risks, which may form an attractive therapeutic approach for combating atherosclerosis-related diseases in the near future.
