Dehydratase mediated 1-propanol production in metabolically engineered *Escherichia coli*

Rachit Jain and Yajun Yan*

**Abstract**

**Background:** With the increasing consumption of fossil fuels, the question of meeting the global energy demand is of great importance in the near future. As an effective solution, production of higher alcohols from renewable sources by microorganisms has been proposed to address both energy crisis and environmental concerns. Higher alcohols contain more than two carbon atoms and have better physicochemical properties than ethanol as fuel substitutes.

**Results:** We designed a novel 1-propanol metabolic pathway by expanding the well-known 1,2-propanediol pathway with two more enzymatic steps catalyzed by a 1,2-propanediol dehydratase and an alcohol dehydrogenase. In order to engineer the pathway into *E. coli*, we evaluated the activities of eight different methylglyoxal synthases which play crucial roles in shunting carbon flux from glycolysis towards 1-propanol biosynthesis, as well as two secondary alcohol dehydrogenases of different origins that reduce both methylglyoxal and hydroxyacetone. It is evident from our results that the most active enzymes are the methylglyoxal synthase from *Bacillus subtilis* and the secondary alcohol dehydrogenase from *Klebsiella pneumoniae*, encoded by *mgsA* and *budC* respectively. With the expression of these two genes and the *E. coli ydjG* encoding methylglyoxal reductase, we achieved the production of 1,2-propanediol at 0.8 g/L in shake flask experiments. We then characterized the catalytic efficiency of three different diol dehydratases on 1,2-propanediol and identified the optimal one as the 1,2-propanediol dehydratase from *Klebsiella oxytoca*, encoded by the operon *ppdABC*. Co-expressing this enzyme with the above 1,2-propanediol pathway in wild type *E. coli* resulted in the production of 1-propanol at a titer of 0.25 g/L.

**Conclusions:** We have successfully established a new pathway for 1-propanol production by shunting the carbon flux from glycolysis. To our knowledge, it is the first time that this pathway has been utilized to produce 1-propanol in *E. coli*. The work presented here forms a basis for further improvement in production. We speculate that dragging more carbon flux towards methylglyoxal by manipulating glycolytic pathway and eliminating competing pathways such as lactate generation can further enhance the production of 1-propanol.

**Background**

The excessive utilization of petroleum plays a major role in the release of the green house gas-carbon dioxide contributing to global warming. Renewable energy sources provide a wide platform of resources to address the problem of increasing energy demand. The manufacture of biofuels such as higher chain alcohols from renewable sources provides an alternative energy source which possesses the advantage of having desirable fuel properties and uncomplicated transportability [1-4]. The synthesis of various higher chain alcohols has been achieved by constructing biosynthetic pathways in *E. coli* and other microorganisms [1-7]. Here, we describe the design of a new pathway for 1-propanol synthesis and its validation in *E. coli*.

In petrochemical industry, 1-propanol is produced from ethene by a reaction with carbon monoxide and hydrogen to give propionaldehyde, which is then hydrogenated [8]. 1-propanol is also produced as a by-product when potatoes or grains are fermented during the commercial manufacture of ethanol [8,9]. The general use of 1-propanol is in the manufacture of drugs and cosmetics such as lotions,
soaps, and nail polishes. It also finds applications in the manufacture of flexographic printing ink and textiles [8,9].

Recently, the use of 1-propanol as a potential fuel substitute to petroleum has promoted the interest in its production via biological approaches. In 2008, Atsumi et al. and Shen et al. reported the production of 1-propanol from glucose by metabolic engineering of E. coli. Their work relied on the keto-acid pathway in E. coli with 2-ketobutyrate as a key intermediate [1,7]. The 2-ketobutyrate was converted to 1-propanol by the action of a keto acid decarboxylase and an alcohol dehydrogenase. Wild type E. coli carrying this pathway was able to produce around 0.15 g/L of 1-propanol. With the elimination of the genes metA, tdh, ilvB, ilvL and adhE encoding the enzymes o-succinyltransferase, threonine dehydrogenase, acetoxyhydrox acid synthase and alcohol dehydrogenase respectively, the production of 1-propanol achieved was 1 g/L. Atsumi et al. [2] reported higher levels of 1-propanol production in E. coli using cimA encoding a citramalate synthase from Methanococcus jannaschii. They established a direct route for the conversion of pyruvate to 2-ketobutyrate. With the utilization of citramalate pathway and incorporating an evolutionary strategy based on growth they were able to overcome feedback inhibition by isoleucine. Using wild type cimA they achieved 0.3 g/L of 1-propanol production. With the development of cimA variants, the production of 1-propanol was 9 times higher compared to the wild type cimA.

We developed a new approach for the biosynthesis of 1-propanol by extending the well-known 1,2-propanediol pathway. As the pathway scheme shown in Figure 1, the intermediate of glycolysis dihydroxyacetone phosphate is converted to methylglyoxal by the action of the enzyme methylglyoxal synthase. The methylglyoxal generated is further reduced to either hydroxyacetone or lactaldehyde via two different routes. The formation of hydroxyacetone is catalyzed by the enzyme methylglyoxal reductase which is a primary alcohol dehydrogenase, while a secondary alcohol dehydrogenase such as glycerol dehydrogenase reduces methylglyoxal into lactaldehyde. Both hydroxyacetone and lactaldehyde can be further reduced to 1,2-propanediol by either a secondary alcohol dehydrogenase or a primary alcohol dehydrogenase. The dehydration of 1,2-propanediol into 1-propanal can be achieved by a diol dehydratase. The conversion of 1-propanol to 1-propanol is also catalyzed by a primary alcohol dehydrogenase.

The pathway that leads to the synthesis of 1,2-propanediol has been introduced into both E. coli and Saccharomyces cerevisiae. By over-expressing the E. coli genes mgsA and gldA and relying on the native expression of other enzymes, Altaras et al. achieved the production of 0.7 g/L of 1,2-propanediol in E. coli [10]. 1.08 g/L 1,2-propanediol production in E. coli was reported by Berrios-Rivera et al. by utilizing Clostridium acetobutylicum mgsA and E. coli gldA in a strain deficient in lactate production and using an initial glucose concentration of 101.68 mM [11]. Enhanced production of 1,2-propanediol in E. coli was also reported by Altaras et al. [12]. The study involved expression of more complete pathway by addition of fucO gene (1,2-propanediol oxidoreductase) responsible for the conversion of lactaldehyde to 1,2-propanediol and deletion of the competing pathway for lactate which involves the gene ldhA. Shake flask fermentation with the ldhA- strain carrying the pathway led to the production of 1,2-propanediol at a titer of 1.27 g/L, while fed-batch fermentation gave a result of 4.5 g/L of 1,2-propanediol. 1,2-propanediol production in S. cerevisiae was achieved by Joon-Young et al. [13]. Their strategy was based on the idea of channeling the carbon flux towards dihydroxyacetone phosphate with the deletion of triosphosphate isomerase in S. cerevisiae via triple homologous recombination. With the introduction of 1,2-propanediol pathways consisting of the E. coli genes mgsA and gldA, the engineered S. cerevisiae produced 1.11 g/L of 1,2-propanediol compared to 0.89 g/L produced from the strain lacking the gene tip1.

In this study, we first constructed the 1,2-propanediol pathway in the wild type E. coli strain BW25113 by expressing the genes, mgsA from B. subtilis, budC from K. pneumoniae, and native E. coli ydjG, which resulted in the production of 1,2-propanediol at a titer of 0.8 g/L in shake flasks. We further achieved the conversion of 1,2-propanediol to 1-propanol via two successive enzymatic steps by expressing the operon ppdABC from K. oxytoca and using the native activity of E. coli alcohol dehydrogenases [14-16]. This established a new pathway for 1-propanol production by engineering the glycolytic pathway in E. coli.

Results and Discussion
Methylglyoxal Synthase Assay
1,2-Propanediol pathway branches from glycolysis and competes for the intermediate dihydroxyacetone phosphate, with the glycolytic pathway. The first enzyme of 1,2-propanediol pathway, methylglyoxal synthase catalyzing irreversible conversion of dihydroxyacetone-phosphate to methylglyoxal holds paramount importance in channeling carbon flux towards 1,2-propanediol biosynthesis [10,11]. Highly active methylglyoxal synthase is therefore desirable. We screened the activity of methylglyoxal synthase from eight different sources. We amplified the mgsA genes from the microorganisms: C. acetobutylicum (ATCC# 824), B. subtilis 168, C. difficile R20291, E. coli MG1655, T. thermophilus HB27, K. pneumoniae MGH78578, P. fluorescens Pf-5, and R. eutropha H16 respectively. These genes were cloned and expressed in wild type E. coli BW25113 using eight plasmids pRJ1-pRJ8. Each gene was under the control of the IPTG-inducible pLlacO1 promoter. Using dihydroxyacetone-phosphate as the substrate, we successfully
detected the functional expression of all mgsA genes in vitro, where the specific activities varied from 0.0052 U/mg to 0.1242 U/mg (Table 1). We identified most suitable methylglyoxal synthase as the mgsA from B. subtilis demonstrating the highest ratio of specific activity/K_m (0.1186) and having a specific activity of 0.0561 U/mg. Without the over-expression of mgsA gene, we also detected the native expression of E. coli mgsA, which gave a specific activity of only 0.0008 U/mg, much lower than that of any over-expression.

**Methylglyoxal Reductase Assay**

We examined the activity of E. coli methylglyoxal reductase encoded by the gene ydjG by using plasmid pRJ10. As a part of aldo-keto reductase family, the product of ydjG executes a catalytic activity of reduction on methylglyoxal.

---

**Table 1 Methylglyoxal synthase assay results**

| mgsA source  | Specific Activity (U/mg) | K_m (mM)   | Specific Activity/K_m (U/mg/mM) |
|--------------|--------------------------|------------|---------------------------------|
| C. acetobutylicum | 0.054 ± 0.004            | 0.776 ± 0.005 | 0.069                           |
| B. subtilis   | 0.056 ± 0.003            | 0.473 ± 0.07  | 0.118                           |
| C. difficile  | 0.059 ± 0.003            | 1.439 ± 0.06  | 0.041                           |
| E. coli       | 0.124 ± 0.006            | 1.418 ± 0.12  | 0.087                           |
| T. thermophilus | 0.016 ± 0.004            | 2.118 ± 0.07  | 0.007                           |
| K. pneumoniae | 0.016 ± 0.009            | 2.820 ± 0.3   | 0.005                           |
| P. fluorescens| 0.013 ± 0.008            | 1.560 ± 0.02  | 0.008                           |
| R. eutropha   | 0.005 ± 0.000            | 0.700 ± 0.03  | 0.007                           |

Substrate dihydroxyacetone phosphate concentration was varied from 0.15 mM to 1.5 mM for all reactions. 1 unit (U) was defined as the amount (μmoles) of methylglyoxal formed per unit time (min).
using NADH to generate hydroxyacetone [17]. We determined both the specific activity and substrate affinity of *E. coli* methylglyoxal reductase on methylglyoxal. When the gene is over-expressed by pRJ10, the specific activity was determined to be 1.62 ± 0.012 U/mg. The enzyme also showed sufficient substrate specificity with a $K_m$ value of 3.31 ± 0.02 mM.

**Secondary Alcohol Dehydrogenase Assay**

The synthesis of 1,2-propanediol from methylglyoxal occurs through two different pathways. For the pathway via lactaldehyde leading to 1,2-propanediol formation we evaluated the activities of two NADH dependent secondary alcohol dehydrogenases: *E. coli* glycerol dehydrogenase (gldA) and *K. pneumoniae* diol dehydrogenase (budC) on methylglyoxal. We also tested the catalytic properties of these two secondary alcohol dehydrogenases on hydroxyacetone for the completion of the other pathway.

The genes gldA and budC were cloned and expressed in *E. coli* using the plasmid pRJ9 and pYY109. The specific activity and $K_m$ value of glycerol dehydrogenase and diol dehydrogenase were determined for the substrates methylglyoxal and hydroxyacetone. Both enzymes showed dehydrogenation activity leading to the conversion of methylglyoxal to lactaldehyde and hydroxyacetone to 1,2-propanediol. Table 2 provides the results of this assay. The diol dehydrogenase and glycerol dehydrogenase demonstrated a specific activity of 3.718 U/mg with a $K_m$ value of 0.78 mM; while the glycerol dehydrogenase showed a lower specific activity (2.456 U/mg) and substrate affinity ($K_m = 68.24$ mM). Similar results were observed when hydroxyacetone was used as a substrate, the diol dehydrogenase more efficiently reduced hydroxyacetone into 1,2-propanediol (specific activity = 4.97 U/mg; $K_m = 1.83$ mM) compared with the glycerol dehydrogenase (specific activity = 0.912 U/mg; $K_m = 10.47$ mM).

**Propanediol Dehydratase in vivo Assay**

The diol dehydratases we tested included a propanediol dehydratase (PPD) originating in *K. oxytoca*, a glycerol dehydratase (GLD) from *K. pneumoniae*, and a glycerol dehydratase (GLD) from *C. butyricum*. The PPD of *K. oxytoca* demonstrates a specific activity of 3.71 ± 0.06 U/mg with a $K_m$ value of 0.78 ± 0.03 U/mg; while the GLD of *K. pneumoniae* demonstrated a specific activity of 2.45 ± 0.00 U/mg with a $K_m$ value of 68.24 ± 0.05 U/mg; while the GLD from *C. butyricum* was determined to be 1.83 ± 0.63 U/mg. The decrease in absorbance of NADH at 340 nm was recorded and used for calculations using the substrates methylglyoxal and hydroxyacetone. Substrate concentration was varied from 20 mM - 120 mM. 1 unit (U) was defined as the amount (μmoles) of product formed per unit time (min).

**Table 2 Specific activity and $K_m$ determination of the secondary alcohol dehydrogenases**

| Gene       | Methyglyoxal Specific Activity (U/mg) | Methyglyoxal $K_m$ (mM) | Hydroxyacetone Specific Activity (U/mg) | Hydroxyacetone $K_m$ (mM) |
|------------|--------------------------------------|-------------------------|----------------------------------------|--------------------------|
| gldA       | 2.45 ± 0.00                          | 68.24 ± 0.05            | 0.91 ± 0.00                            | 10.47 ± 0.55             |
| budC       | 3.71 ± 0.06                          | 0.78 ± 0.03             | 4.97 ± 0.00                            | 1.83 ± 0.63              |

The decrease in absorbance of NADH at 340 nm was recorded and used for calculations using the substrates methylglyoxal and hydroxyacetone. Substrate concentration was varied from 20 mM - 120 mM. 1 unit (U) was defined as the amount (μmoles) of product formed per unit time (min).
Production of 1,2-Propanediol and 1-Propanol in E. coli

In order to introduce the 1-propanol pathway into wild type E. coli strain BW25113, we constructed two plasmids. The first plasmid pRJ11 carries the genes encoding the most active enzymes for 1,2-propanediol biosynthesis. Specifically, mgsA from B. subtilis, ydjG from E. coli, and budC from K. pneumoniae were organized as a synthetic operon under the control of IPTG-inducible pLacO1 promoter in a high-copy number plasmid. The second plasmid pYY93 contains only the structural genes ppdABC encoded by K. oxytoca PPD. For the enzymatic steps of lactaldehyde to 1,2-propanediol and 1-propanol to 1-propanol, we completely relied on the native expression of alcohol dehydrogenases in E. coli, as is indicated to be sufficient [10,11]. We also evaluated M9 media in comparison to low-phosphate media for the production of 1,2-propanediol (Data not provided). The results of an initial experiment show significant increase in production using low-phosphate media. Using M9 media resulted in only about 0.1 g/L of 1,2-propanediol generation after 48 hours of anaerobic fermentation compared to about 0.8 g/L from low-phosphate media. Hence low-phosphate media was used for all fermentation studies. The culture conditions were the same as described in “Methods and Materials”.

We first transformed the plasmid pRJ11 into wild type E. coli strain BW25113 to achieve 1,2-propanediol production. It has been reported that the enzyme methylglyoxal synthase is inhibited by phosphate ion [22,23]. The inhibition of methylglyoxal synthase would result in the carbon flux being diverted to glyceraldehyde-3-phosphate instead of methylglyoxal by the conversion action of triose phosphate isomerase. Therefore a low-phosphate media was employed to avoid this problem. The fermentation experiments were conducted in 20 ml cultures as described in the “Methods and Materials”. The fermentation samples were collected after 24 hours and 48 hours and analyzed by HPLC-RID. As the results shown in Table 3, after 24 hours 0.66 g/L 1,2-propanediol was produced. The production reached 0.80 g/L after 48 hours. Lactate was detected as the dominant by-product and was accumulated at over 7 g/L. We also conducted the experiments aerobically. However, only a trace amount (< 0.01 g/L) of 1,2-propanediol was produced and the cell growth was much better than in anaerobic conditions, which indicates that glycolysis is very active in aerobic condition and drags almost all carbon flux towards pyruvate for cell growth or other cell activities.

With the successful establishment of the pathways for 1,2-propanediol production using pRJ11, we hypothesized that the co-expression of pRJ11 with pYY93 would result in the production of 1-propanol. To test this, wild type E. coli BW25113 was transformed with both pRJ11 and pYY93 for 1-propanol production by electroporation. The fermentation condition was similar to that used for 1,2-propanediol production with the addition of 10 μM coenzyme B-12 to the culture along with IPTG (0.1 mM) after 6 hours. After 24 hours, the double transformed strain produced 0.11 g/L 1-propanol with 0.44 g/L 1,2-propanediol remaining unconverted (Table 3). After 48 hours, 1-propanol was produced at 0.25 g/L with 0.46 g/L 1,2-propanediol remaining unconverted. The major by-product was again lactate at over 7 g/L.

Conclusions

We have successfully established a new pathway for 1-propanol production by shunting the native glycolytic pathway in E. coli. The addition of the coenzyme B-12 dependent propanediol dehydratase from K. oxytoca resulted in the conversion of 1,2-propanediol to 1-propanol which was then dehydrogenated by E. coli native activity to 1-propanol.

From the assay of methylglyoxal synthase it was determined that the mgsA from B. subtilis was the most active. Since the accumulation of methylglyoxal in high quantities is toxic to the cell [24], it is important that the generated methylglyoxal is immediately converted to another metabolite by the downstream enzymes in the pathway.

Table 3 1,2-Propanediol and 1-propanol production in low-phosphate media using E. coli strain BW25113 transformed with the appropriate plasmid(s)

| Plasmid | 1,2-Propanediol (g/L) | 1-Propanol (g/L) |
|---------|-----------------------|-----------------|
|         | 24 h                  | 48 h            | 24 h               | 48 h               |
| pRJ11   | 0.66 ± 0.01           | 0.80 ± 0.01     | ———               | ———               |
| pRJ11 and pYY93 | 0.44 ± 0.01         | 0.46 ± 0.02     | 0.11 ± 0.01       | 0.25 ± 0.07       |
To address this problem we screened the activity of methylglyoxal reductase and two secondary alcohol dehydrogenases.

To evaluate 1, 2-propanediol formation, methylglyoxal synthase (mgsA) from B. subtilis and propanediol dehydrogenase (budC) from K. pneumoniae were expressed leading to the conversion of dihydroxyacetone phosphate to 1,2-propanediol via the formation of methylglyoxal and lactaldehye. To strengthen our constructed pathway the introduction of E. coli methylglyoxal reductase (ydhG), a dual metabolic route for production of 1, 2-propanediol was established for the first time. This resulted in channeling the carbon flux from methylglyoxal to hydroxyacetone and 1,2-propanediol. Fermentation with E. coli BW25113 transformed with pRJ11 carrying the three above mentioned genes produced 0.8 g/L 1,2-propanediol after 48 hours of anaerobic fermentation.

We also evaluated the use of a medium copy number vector (pRJ12) for 1, 2-propanediol production (data not provided). This was done using the same genes used for the construction of high copy number plasmid pRJ11 but in the backbone of a medium copy number vector pCS27. However, the production of 1, 2-propanediol from a medium copy number vector (pRJ12) was found to be significantly lower than the production by high copy number vector (pRJ11). Hence the medium copy number vector was not selected for 1, 2-propanediol and 1-propanol production.

The result of the in vivo enzyme assay (Figure 2) shows almost 100% conversion of 1, 2-propanediol to 1-propanol indicating that the conversion of 1,2-propanediol to 1-propanol was very efficient and that the native expression of alcohol dehydrogenases in E. coli is sufficient in converting 1-propanol to 1-propanol. However, it was not the case for the strain carrying the plasmids pRJ11 and pYY93 which showed much lower conversion of 1,2-propanediol to 1-propanol as about 0.46 g/L of 1,2-propanediol after 48 hours of anaerobic fermentation.

Overall, the work presented here represents 1-propanol production in a wild type E. coli strain and forms a basis for further enhancement in production. The effect of competing pathways is significant and the deletion of the same has not been explored in this study. We speculate that by the knock-out of genes encoding for lactate dehydrogenase (ldhA), glyoxalase (gloA) and other competing pathways (tpiA and zwf) the production of 1-propanol can be further enhanced, which will be pursued in the near future.

Materials and methods

Chemicals and Reagents

Hydroxyacetone was bought from Acros Organics (New Jersey, USA); methylglyoxal and 1,2-propanediol were purchased from Sigma Aldrich (St. Louis, Mo); 1-propanol was obtained from Fisher Scientific (Atlanta, GA). KOD DNA polymerase was obtained from EMD Chemicals Inc., NJ. All restriction enzymes were bought from New England Biolabs (Beverly, MA). The rapid DNA ligase was obtained from Roche Applied Science (Indianapolis, IN). All the enzymes were used according to the instructions of the manufacturer.

Plasmids and Strains

E. coli strain XL1-Blue (Stratagene, CA) was used for DNA manipulations; while wild type E. coli strain BW25113 (E. coli Genetic Resource Center, CT) and E. coli strain BL21* (Invitrogen) were employed for enzyme assays and shake flask experiments. Plasmids pZE12-luc [29], pCS27 [7] and pCDF-Duet1 (EMD Chemicals Inc., NJ) were used for DNA cloning. The features and descriptions of the used strains and plasmids are listed in Table 4.

DNA manipulations

All DNA manipulations were performed according to the standard procedures as described previously [30]. The primers involved in DNA manipulations are listed in Table 5. The plasmids listed in Table 4 were constructed as described below.

For the methylglyoxal synthase assay, the plasmids pRJ1-pRJ8 were constructed by cloning mgsA genes from eight different sources into the vector pZE12-luc.
the DNA fragments obtained were digested with restriction enzymes for three hours. The DNA fragments obtained were digested with the appropriate restriction enzymes from C. acetobutylicum (ATCC824), B. subtilis 168, Clostridium difficile R20291, E. coli MG1655, Thermus thermophilus HB827, K. pneumoniae MGH78578, Pseudomonas fluorescens Pf-5, and Ralstonia eutropha H16 respectively. The DNA fragments obtained were digested with restriction enzymes for three hours. Acc65I and SphI restriction enzymes were used to digest mgsA genes from C. acetobutylicum (ATCC824), B. subtilis 168, C. difficile R20291, E. coli MG1655, T. thermophilus HB827, K. pneumoniae MGH78578, B. subtilis 168, C. difficile R20291, E. coli MG1655, T. thermophilus HB827, K. pneumoniae MGH78578, and other organisms. The mgsA genes were PCR amplified from the genomic DNA of K. pneumoniae MGH78578 using the primers listed in Table 5. The mgsA genes were then inserted into plasmid pZE12-luc. The restriction enzymes used for the construction of plasmid pYY109 were BamHI and SalI.

For diol dehydratase assay, plasmids pYY93, pYY134, and pYY167 were constructed. The ppdABC operon obtained via PCR from the genomic DNA of K. oxytoca was digested with restriction enzymes SfiI and HindIII and inserted into plasmid pCS27 digested by SfiI and HindIII. Similarly, the gldABC operon was PCR amplified from genomic DNA of K. pneumoniae MGH78578 and inserted into pCS27 using restriction enzymes Acc65I and HindIII. To construct pYY167, we first synthesized the operon dhaB12 from Clostridium butyricum by PCR assembly of 50 bp oligonucleotides designed from Helix Systems (NIH). The codons were optimized for E. coli standard expression. The operon was cloned into pCS27 using Acc65I and HindIII, forming pYY167.

Following the enzyme assays, plasmid pRJ11 was constructed using the most active enzymes in order to produce 1, 2-propanediol. The plasmid pRJ11 was generated via the ligation of three genes on the backbone of pZE12-luc vector. The genes ydhG, budC, and mgsA were PCR amplified using the primers listed in Table 5 from the genomic DNA of E. coli MG1655, K. pneumoniae MGH78578 and B. subtilis 168, respectively. Following this, the PCR amplified ydhG gene product was digested.

### Table 4 List of strains and plasmids used in this study

| Strain | Genotype | Reference |
|--------|----------|-----------|

with Acc65I and SalI. The PCR amplified budC gene product was digested with SalI and PstI, and the PCR amplified mgsA gene was digested with PstI and XbaI. Vector pZE12-luc was digested with Acc65I and XbaI. After digestion for three hours, the three gene fragments and the vector were ligated simultaneously, creating pRJ11. It should be noted that RBS sequence (AGGAGA) was inserted upstream of each structure gene with 6-8 nucleotides in between to facilitate protein translations.

**Culture Medium and Fermentation Conditions**

M9 minimum was used for the in-vivo assay of propanediol dehydratase and low-phosphate minimum medium was used for shake flask fermentations. M9 minimum media consisted of (per liter): 20 g glucose, 5 g yeast extract, 12.8 g Na2HPO4·7H2O, 3 g KH2PO4, 0.5 g NaCl, 1 g NH4Cl, 0.5 mM MgSO4, and 0.05 mM CaCl2. The low-phosphate media consisted of (per liter): 20 g glucose, 5 g NaCl, 5 g yeast extract, 1.5 g KCl, 1 g NH4Cl, 0.2 g MgCl2, 0.07 g Na2SO4, and 0.005 g FeCl3, which was buffered to pH 6.8 with 13.3 g of NaHCO3 and 10 g of 3-[N-morpholino]propanesulfonic acid (MOPS) [10,12].

For the shake flask fermentations, 1 mL of seed culture was prepared in LB media containing necessary antibiotics and grown overnight at 37°C in a shaker set at 250 rpm. After overnight incubation, the culture was inoculated into 20 mL of M9 or low-phosphate media containing appropriate antibiotics in 150 mL serum bottles. After growing at 37°C for 3 hours, the cultures were switched to an anaerobic condition by sparging nitrogen gas. IPTG was added into the culture to a final concentration of 0.1 mM 6 hours after inoculation to induce protein expression. Then the fermentation was carried out at 30°C at 250 rpm. Samples were taken after 24 and 48 hours and analyzed with HPLC-RID.

**HPLC-RID Analysis**

The analysis of fermentation products was done via HPLC (Shimadzu) equipped with a Coregel-64H column (Transgenic). 1 mL sample was collected and centrifuged at

Underlined nucleotides represent restriction sites. Italicized nucleotides represent ribosome binding sites inserted in the primer.
15,000 rpm for 10 minutes and the supernatant was filtered and used for analysis. The mobile phase used was 4 mM H$_2$SO$_4$ having a flow rate of 0.6 mL/min and an oven temperature set at 60°C [31].

**Enzyme Crude Extract Preparation**

*E. coli* strain BL21* was employed to express budC carried by pYY109. Expression of other individual enzymes was conducted in the wild type *E. coli* strain BW25113 harboring the corresponding plasmids. Generally, the transformed strains were pre-inoculated into LB liquid medium containing appropriate antibiotics and grown at 37°C overnight with shaking. The following day, 1 mL of preinoculum was added to 50 mL of fresh LB medium containing necessary antibiotics. The culture was left to grow at 37°C with shaking until the OD$_{600}$ reached approximately 0.6. At that point, IPTG was added to a final concentration of 1 mM and the protein expression was conducted at 30°C for 3 hours. The cells were collected by centrifugation at 5000 rpm for 10 min at 4°C. The cell pellets were resuspended in 2 mL of 50 mM imidazole-HCl buffer (pH 7.0). Cell disruption was performed using French Press, and soluble protein was obtained by ultra-centrifugation for enzyme assays. Total protein concentration was estimated using the BCA kit (Pierce Chemicals).

**Methylglyoxal Synthase Assay**

Methylglyoxal synthase assay was performed as described previously with minor revisions [10,11,23]. The assay was carried out using a two step procedure. The reaction mixture (500 μl) consisted of 50 mM imidazole-HCl buffer (pH 7.0), 0.15-1.5 mM dihydroxyacetone phosphate, and 25 μl crude extract. Reaction was started with the addition of 25 μl crude extract to the reaction mixture and incubated in a water bath at 30°C for 30 seconds. Followed by this, the reaction was immediately stopped by the addition of 30 μl sample of the reaction mixture to the detection mixture and incubated in a water bath at 37°C for 15 minutes. The detection mixture consisted of 300 μl of DI water, 110 μl of 0.1% 2, 4-dinitrophenylhydrazine dissolved in 2N HCl. After the completion of 15 minutes 550 μl of 10% NaOH was added to the detection mixture and then incubated at room temperature for another 15 minutes. (Final volume of detection mixture = 990 μl). The samples were diluted 10 times before measuring the absorbance at 550 nm. 1 μmol of methylglyoxal has an absorbance value of 16.4 at 550 nm [11].

**Methylglyoxal reductase assay**

The reaction mixture contained 20-120 mM methylglyoxal and 0.25 mM NADH, in imidazole-HCl buffer (pH 7.0) having a final volume of 970 μl. The assay was begun with the addition of 30 μl crude extract to the reaction mixture. The reaction was allowed to proceed for 60 seconds at 37°C. We measured the decrease in absorbance of NADH at 340 nm to calculate the specific activity [10,11].

**Secondary Alcohol Dehydrogenase Assay**

The enzyme crude extracts prepared from gldA and budC expression were used for this assay. The reaction mixture consisted of 20-120 mM of methylglyoxal or hydroxyacetone and 0.25 mM NADH in imidazole-HCl buffer at (pH 7.0) with a final volume of 970 μl. The assay was begun with the addition of 30 μl crude extract to the reaction mixture. The reaction was allowed to proceed for 60 seconds at 37°C. We measured the decrease in absorbance of NADH at 340 nm to calculate the specific activity [10,11].

**Propanediol Dehydratase in vivo Assay**

The assay was carried out to evaluate the activities of three diol dehydratases on 1,2-propanediol. Three *E. coli* strains generated by transforming the wild type *E. coli* BW25113 with pYY93, pYY134, and pYY167 respectively were used for this purpose. Preinoculum from an overnight culture was added to 10 mL of M9 media (1:100 V/V) and grown at 37°C. IPTG was added to the cultures to a final concentration of 0.1 mM and 1,2-propanediol was added to the cultures as the substrate to a final concentration of 5 g/L (65.7 mM) after 4 hours. The cell cultures carrying pYY167 was grown anaerobically; while the cell cultures carrying pYY93 or pYY134 were grown micro-aerobically. Coenzyme-B12 (cobamamide) was also added to the cell cultures having pYY93 and pYY134 to a final concentration of 0.1 μM after 4 hours. Samples were collected after 24 hours and analyzed for 1-propanol generation using HPLC-RID as described above. The enzyme activities were reflected by the formation of 1-propanol.

**Acknowledgements**

This work was supported by start-up funds from the Faculty of Engineering, The University of Georgia, Athens. We would also like to thank Dr. Mark Eiteman for his insight on enzyme assays and Sarah Lee for her technical assistance.

**Authors’ contributions**

YY and RJ conceived the study. RJ performed the experiments under the guidance of YY. An equal contribution by YY and RJ was made for literature review and drafting of the manuscript. Both authors read and approved the final manuscript.

**Competing interests**

The authors declare that they have no competing interests.
