Abstract
In this article, an ongoing research is presented, the immediate goal of which is to create a corpus annotated with semantic role labels for Hungarian that can be used to train a parser-based system capable of formulating relevant questions about the text it processes. We briefly describe the objectives of our research, our efforts at eliminating errors in the Hungarian Universal Dependencies corpus, which we use as the base of our annotation effort, at creating a Hungarian verbal argument database annotated with thematic roles, at classifying adjuncts, and at matching verbal argument frames to specific occurrences of verbs and participles in the corpus.

1 Introduction
Recently, state-of-the-art performance in most NLP related tasks has been achieved by end-to-end systems based on neural deep learning networks (see e.g. BERT (Devlin et al., 2018) or GPT-2 (Radford et al., 2019)) surpassing the performance of previous systems employing some sort of grammatical analysis. This has raised doubts as to whether it makes sense to deal with grammatical analysis at all. At the same time, the training of end-to-end systems usually requires a great amount of training material, which is not available in most languages. Therefore, we think it may still make sense put an effort into the implementation of a grammatical analysis framework as long as the output of the system can be directly used to perform tasks relevant to everyday users.

However, we cannot be satisfied with an analysis that relies on completely abstract categories that cannot be clearly translated into terms that can be linked to what that text means in a manner that can also be understood by ordinary people. An essential element of reading comprehension is that we are able to ask meaningful questions about the given text, and this ability is closely related to the ability to answer questions. Therefore, our aim is to create a system that is actually capable of formulating relevant questions about the text it processes. To do this, many distinctions need to be made that are not present in syntactic annotation currently available for Hungarian. This article presents the first phase of this work, which aims to create an annotated corpus where the annotation contains all the features needed to generate questions concerning the text.

2 Shortcomings of the traditional analysis
Since our goal is to create a system that can generate meaningful questions, we have decided that when determining what distinctions need to be made in the annotation should be basically determined by what questions can be asked concerning the particular grammatical construction. For example, in order to be able to formulate questions concerning noun phrases, the Who/What? distinction is indispensable, so the system must be able to clearly distinguish persons from things. At the same time, we ask who or what questions concerning NP’s that refer to groups or organizations depending on the role they play in the given sentence. For example, a bank is referred to linguistically as a person when sending an invoice letter, but as a thing when it is liquidated. In addition, a more detailed classification is required to generate questions about nominal predicates. Concerning the predicate in the sentence John is a doctor, the question Who is John? is not very sophisticated. What is John’s occupation? is a question matching the predicate in the sentence much more precisely. Classifying concepts as occupations, animals, tools, behaviors, etc. also makes for the system possible to generate more specific
questions related to non-predicative occurrences of noun phrases: e.g. What animal have you seen in the garden? vs. What did you see in the garden? This is particularly important in the case of coordinated phrases where one can only identify which conjunct is meant in the question if the question is specific enough.

To formulate questions concerning adverbials even at the most basic level, we also need a much more detailed system of distinctions than what is provided by the syntactic annotation present in currently available tree banks. Hungarian NP's headed by a word in inessive case or corresponding English PP's headed by the preposition in can have quite a number of different grammatical functions. Thus we ask different questions concerning them: (1) szeptemberben 'in September': mikor? 'when?', (2) Londonban 'in London': hol? 'where?', (3) fájdalmában (felüvöltött) '(he screamed) in pain': mitől? 'what made (him scream)?', (4) magában (hisz) 'he believes' in himself': kiben? 'in whom?', (5) bajban 'in trouble': milyen helyzetben? 'in what situation?', (6) életben (marad) 'stay' in life': kiben? 'in whom?', (5) bajban 'in trouble': milyen helyzetben? 'in what situation?', (6) életben (marad) 'stay' in life': kiben? 'in whom?'

Generating questions concerning not only nominal but also verbal predicates requires information not provided by currently available annotation for Hungarian. How a question concerning a verbal predicate should be formulated using specific arguments as anchors depends on the thematic roles the arguments play. What did John do to Frank? is an adequate question if John is an agent and Frank is a patient. In the same situation, What happened to Frank? and What did John do? are likewise adequate questions.

Identification of thematic roles of verbal argument slots is also needed in order to be able to distinguish oblique arguments from semantically compositional relations (e.g. locative and oblique uses of in: believe in something vs. be somewhere). We also need to distinguish parts of idioms and light verb constructions from compositional verb-to-argument relations. It is a joke to ask a question concerning a non-compositionally related constituent:

What are you holding? — A meeting.

3 The corpus
As a starting point, we chose the Hungarian subcorpus (Vincze et al., 2017) of the Universal Dependencies (UD) corpus (Nivre et al., 2016) consisting of 1800 sentences (42000 tokens) of mainly newswire text in order to put the annotation schema we propose in a context that can be interpreted at an international level. The UD corpus contains texts in many languages annotated with morphosyntactic and dependency-based syntactic analysis using unified principles and categories. Our original plan was to supplement or refine the annotation in the Hungarian UD corpus with the information needed to formulate questions. However, it turned out that the annotation in the Hungarian sub-corpus does not correspond to the currently valid UD specification in many respects, and contains many random annotation errors, so fixing these errors turned out to be an inevitable part of our task.

According to the UD 2.0 specification, the internal structure of multiword expressions is to be annotated using the flat, fixed or compound dependency relations. The fixed relation is used exclusively to annotate fully lexicalized function-word-like structures. In many languages, such as English, multiword names are generally considered to be flat exocentric structures, and the use of flat is suggested to annotate the internal structure of these names with all words of the name directly attached to the first word of the name. On the other hand, the UD 2.0 annotation specification explicitly excludes the use of this type of analysis in cases where the name has a regular syntactic structure (e.g. in the case of book or movie titles or a large part of names of organizations). Here the generic syntactic dependency structures are to be used. Similarly, endocentric structures should be annotated using the compound relation or one of its sub-types (see e.g. Kahane et al. (2017) on the contradiction of applying the flat annotation to languages where names are endocentric). Hungarian noun phrases are always right-headed endocentric structures, so in the case of names that do not have a regular structure and compositional meaning, the compound relation is to be used. This ensures,
for example, that case endings always attached to the head of the NP are directly accessible. E.g. the head of an object NP is always in the accusative case in Hungarian. The current annotation for names completely obscures this fact (see e.g. *az Egyesült Államok ‘the united states’ Acc* in Figure 1). Therefore, as one of the preprocessing steps, all multiword names, originally erroneously annotated in the corpus as flat structures, were automatically converted into compound structures (Figure 1). For the time being, the identification and further reannotation of names with a completely regular structure has not been done, as this requires manual intervention.

Structures like *Angela Merkel német kancellár ‘German Chancellor Angela Merkel’* were often erroneously annotated as appositive structures in the corpus. We converted these structures introducing the *compound:title_of* relation between the name and the occupation/role.

The UD 2.0 specification prescribes the use of the *obl* relation to attach NP arguments other than subjects, objects or indirect objects even in the case of nonverbal heads. Often, some other relation was used in the corpus even for verbal arguments. We were able to automatically correct most of these annotations in the case of arguments of verbs and participles (Figure 2).

In Hungarian, like in German, verbal particles are detached from the verb in various syntactic constructions, and they are moved to some distinct syntactic position. Nevertheless, these particles are considered part of the verb lemma. The verbal argument database that we created as part of our annotation effort, also contains particle verbs in this form. In the Hungarian UD corpus, on the other hand, verb lemmas did not include the particle in such cases. This needed to be fixed (adding the particle to the verb lemma) in order for the verbal argument frames could be matched to their occurrences in the corpus. Many additional lemmatization errors were fixed, and we also needed to relemmatize participles so that we can match verb argument frames against them.

In Hungarian, demonstrative predeterminers agree in case and number with the head of the NP (*azokat a kutyákat ‘those dogs* CC”). These structures were often annotated erroneously, with the demonstrative predeterminer being attached to the head of the NP using the same dependency label the whole NP was annotated with. We corrected these errors and attached all predeterminers as *det:predet* to the head of the NP (Figure 3).

Further corrections performed automatically included using *nmod:poss* instead of *nmod:att* in possessive structures, (bottom of Figure 2), attaching all postpositions using the *case* relation, and fixing clauses where the subject and the (nominal) predicate were exchanged in the annotation by mistake due to the annotators confusing the focus construction with predications. The latter errors needed to be identified manually, the correction of the identified structures was then performed automatically (Figure 4).

### 4 The argument frame database

All stems of verbs and participles occurring in the Hungarian UD corpus were collected, and they were clustered using agglomerative clustering like in (Síklósi, 2016) based on their vector representation in a word-embedding model constructed from a morphosyntactically annotated corpus (Novák and Novák, 2018). This process effectively clustered verbs having similar distributional patterns (and argument frames). Each verb in the list was supplemented with its surface argument frames from a Hungarian verb-frame dictionary (Sass et al., 2010). Using this initial representation as a source of inspiration, we have described the possible argument frames of each verb manually. Our description contains the thematic role, the surface features (case-ending, postposition, possessive suffix, etc.), possible optionality and, if applicable, lexical/semantic constraints of each argument. Clustering helped us to streamline the process and simplified the task of annotators. Annotating verbs with similar argument frames in a batch together instead of having to process them in some random order made it possible for us to use an inheritance mechanism and improved consistency.

The main point in describing the argument frames of verbs was to provide as much information as possible to make it possible to ask the best, most accurate questions. With that in mind, our set of thematic roles is based on widely known thematic role hierarchies. However, it differs from them in minute details, just like they differ from each other. The description of verbs is intended to cover every possible meaning (argument frame).
Since verbs with similar meanings and argument frames were already grouped in the database, it was possible to specify common argument frames for groups of verbs. These frames are inherited automatically by verbs belonging to the same group. In addition, each verb can have its own argument frame which does not apply to the whole group.

This frame can be added to the record of the specific verb.

The required and optional arguments of each verb are represented either by their thematic roles or lexically, supplemented with the required case-endings or postpositions. The identification of the thematic roles is based on the question that can be asked about the given argument or about the verb with the given argument as an anchor. For example, the question concerning the agent is what is A doing?, the question concerning the patient is what is happening to P?.

Some roles also represent a kind of semantic category, such as CONT which refers to the content of communication, or ACT which denotes an action (usually expressed as an infinitive xcomp). Arguments not having a specific thematic role that could not be used as an anchor when we want to ask a question about the predicate were marked using the semantically neutral theme (TH) thematic role.

The fixed components of idiomatic or semi-compositional verbal structures are not labeled by thematic roles but they are specified lexically.
These structures were supplemented with their own argument frame descriptions (thus interpreted as autonomous units) where this solution seemed to be justified. For example, the description of sor kerül ‘to take place’ (lit. ‘turn comes’) is not part of the description of the word kerül ‘to come’, but we have assigned an argument frame to the whole phrase as a unit. The thematic roles assigned to the verbs and verbal structures are summarized in Table 1.

Since verbs of movement imply the applicability of specific types of questions (e.g. How did X get to Y?), in addition to the roles listed in the table, a special annotation was applied to moving actors: for example moving agents are marked as AGMV. Our basic assumption was that a verb can not have more than one argument having the same thematic role. However, in some cases – where it is necessary – the co-actor is marked with the co- prefix. For example, sétál valakivel ‘to walk with someone’ is represented with AG_coAG-vAl (-vAl stands for the instrumental case-ending).

The argument frames described above could also obtain some special semantic classification which may help in the further refinement of the possible questions. The categories used for this are as follows:

- perception (e.g. to see)
- emotion (e.g. to be glad)
- sound (e.g. to resound)
- situation (e.g. to be pressed for time)
- beginning (e.g. to be established)
- cognitive (e.g. to agree)
- communication (e.g. to inform)
- mathematical (e.g. to add)
- nonverbal communication (e.g. to nod)
- self-propelled motion (e.g. to step)
- financial (e.g. to transfer)
- destruction (of patient, e.g. to dry up)
- natural (e.g. to rain)
- transformation/change (e.g. to speed up)
- behavior (e.g. to flirt)
- relation (e.g. to support)

Finally, the argument frames also have a polarity value indicating that the given event is positive, negative or neutral for the patient or experiencer.

Figure 5 shows the description of the verbs sodrődik ‘to drift’, hull ‘to fall’ and zuhan ‘to drop/plummet’ in the argument frame database. In the first line of the extract, the PATMV_(PATH) frame including an optional PATH argument that can in turn be expanded as any combination of SRC, DST and VIA arguments, as well as the neutral polarity marked with @. For each verb below them. Round brackets in the descriptions indicate optionality, square brackets contain a list of examples defining a semantic category.

At the time of writing this paper, the argument frame database contains 1604 verbs with 5994 different argument frames, including the thematic role of each argument. Although frames containing optional arguments (e.g. olvas AG_ (HOW)_(PAT-t)_(REC-nAk)_(TH-rÓl)_LOC-bAn) ‘somebody reads (somehow) (something) (to somebody) (about something) (somewhere)’) appear as many seemingly different frames in practice, we obtained these numbers by counting the frames containing optional arguments and possible thematic role variants only once.

5 Identifying the role of adjuncts

An important task is to provide a fine-grained description regarding the role of nominalizations with case-ending, traditionally referred to as adjuncts. If we approach the question from the case-endings, we could say that the nominal having an inessive case-ending indicates some kind of location and answers the question Where?. However, if the question is e.g. Where did Mary graduate?, it is a joke to say In her dream. The case-endings answering the questions Hol? ‘Where?’, Hová? ‘Where to?’ and Honnan? ‘From where?’ are not always used to specify the location, the source or the destination. Depending on the lemma, the suffixed forms may express various temporal relations, modality, etc. For most lexical items that can refer to locations, only one set of the suffixes (e.g. only the inessive -bAn ‘in’, illative -bA ‘into’, and the elative -bÓl ‘from inside’) can be used to express location, source and destination), the rest of the suffixes can only be used as markers of specific oblique arguments of verbs. E.g. while for settlements outside Hungary, the locative relation is always expressed using inessive (e.g. Londonban ‘in London’), for most Hungarian settlements, the superessive is used (e.g. Budapesten ‘in Budapest’.

4In Hungarian, locative/lative/delative case-endings are as follows: the inessive -bAn ‘in’, the adessive -nÁl ‘at’, the superessive -On ‘on’; the illative -bA ‘into’, the allative -bÓl ‘from inside’, the ablative -ol ‘from’; the sublative -rA ‘onto’; the elative -bOl ‘from inside’, the ablative -tOl ‘from’; the relative -tOl ‘from the top of’.

Figure 5: An extract from the argument frame database.

Table 1: Thematic roles used in the description of argument frames

| Annotation | Name          | Question regarding the verb                  | Example                        |
|------------|---------------|----------------------------------------------|---------------------------------|
| AG         | agent         | What is AG doing?                            | John has climbed the tree.      |
| CHAR       | characterized | What is characteristic of CHAR?              | Expertise is an advantage.      |
| ATTR       | attribute     | –                                             | Expertise is an advantage.      |
| EXP        | experencer     | How does EXP feel? What has EXP perceived?   | John loves Mary.                |
| PAT        | patient       | What happened to PAT?                        | John has seen a swallow.        |
| PATDST     | patient-destination | What happened to PATDST? Where did PAT get to? | He painted the wall green.      |
| TH         | theme         | –                                             | John relies on his intuition.   |
| ST         | stimulus      | What effect has ST (on EXP)?                 | John loves Mary.                |
| CONT       | information content | –                                          | John presented the plan to Joe. |
| REC        | recipient     | –                                             | John presented the plan to Joe. |
| INS        | instrument    | –                                             | Mary received a letter.         |
| CAU        | causer        | What did CAU cause?                          | John travels to work by scooter.|
| MOT        | motivation    | What was the consequence of CAU?             | John was late because of an accident.|
| LOC        | location      | –                                             | John is studying to be an engineer.|
| SRC        | source, starting point | –                                        | John came out of the room.      |
| DST        | destination   | How did AG/PAT get to DST?                   | John went into the room.        |
| HOW        | mode          | –                                             | John deftly climbed the tree.   |
| ASPECT     | aspect        | –                                             | John is doing well financially. |
| ACT        | action        | –                                             | John wants to work from home.   |

lit. ‘on Budapest’). On the other hand, as oblique arguments of the verbs hisz ‘believe’ and műlik ‘depend’, all nouns take the inessive ‘in’ and the superessive ‘on’ suffixes, respectively. Lemmas can thus be classified concerning what functional/semantic relation is expressed by the combination of the lemma and each case ending. We identified such classes and defined templates that describe the semantic role of each suffixed form in the template. For all words (lemmas) belonging to the specific class, the template yields the semantics of each suffixed form.

The task can also be formulated as a classification of adverbs. There are, of course, adverbs of place such as a sarkon ‘at the corner’ or bankban ‘in a bank’, and adverbs of time such as télén ‘in winter’, decemberben ‘in December’. However, we also find adverbs of duration, e.g. 5 hónapra ‘for five months’ or a category that we could term as ‘adverbs of garment’ such as kabátban ‘wearing a coat’. 31 main categories have been identified, some of which can be divided into several subcategories. Together with the subcategories, we have divided the adverbs having locative case-endings into 51 classes. To illustrate some of the subcategories, in Table 2, we present lemmas which, when combined with a subset of the locative suffixes, function as adverbs of place. When combined with other locative suffixes, they cannot function as heads of adjunct phrases. In these cases, they can only depend on some head word selecting that specific suffix as the marker of a specific oblique argument.

The first two columns of the table show the main category (in this case, loc) and its subcategories (all, ine, city-sup, etc.). This is followed by an
example lemma belonging to the given subcategory, and the best applicable questions for each of the case-endings -bAn, -nÁl and -On, respectively. The questions indicate what role the suffixed word form plays in a sentence.

6 Automatic identification of semi-compositional structures

When identifying idiomatic and semi-compositional verbal constructions, we focused on the behavior of phrases with regard to the relevant question that can be asked about the given phrase. In the case of döntést hoz ‘to make a decision’ (lit. ‘to bring a decision’), What does A bring? is not an acceptable question. Similarly, Where does A bring P? is incorrect regarding the phrase szóba hoz ‘to mention’ (lit. ‘to bring into word’).

We have implemented an algorithm for collecting such phrases from a parallel corpus. First, we generated word alignments in the English-Hungarian parallel subcorpus of the OpenSubtitles corpus consisting of 644.5 million tokens (Lison and Tiedemann, 2016) using the fast align tool (Dyer et al., 2013). To alleviate data sparseness problems due to the rich morphology of Hungarian, to improve alignment quality and to facilitate the subsequent light verb construction and idiom identification process, we used a morphosyntactically annotated version of the corpus. The English side was annotated using Stanford tagger (Toutanova et al., 2003) and the morpha lemmatizer (Minnen et al., 2001), while the Hungarian side using the PurePos tagger (Orosz and Novák, 2013) and the Hungarian Humor morphological analyzer (Novák et al., 2016). We further post-processed the output of the tagger/lemmatizer tool combos, to generate an annotation in which each word is represented by one or two tokens on the Hungarian as well as on the English side. The first token is the lemma with the main POS tag attached to it, while the other optional token consists of possible extra morphosyntactic tags (such as tense, case, etc.) if present. We extracted at most 7-token-long parallel phrases from the word-aligned corpus using the phrase extraction algorithm using the grow-diag-final heuristic implemented in the Moses SMT toolkit (Koehn et al., 2007). Of the pairs of phrases extracted, we only kept pairs containing exactly one verb both on the English and on the Hungarian side. For each Hungarian verb from these phrase pairs, we collected all the nouns on the Hungarian side that were aligned with the verb on the English side. For example, in döntést hoz ‘to make a decision’ (lit. ‘to bring a decision’), the Hungarian verb is hoz ‘to bring’. If it is aligned with the verb decide on the English side, the noun döntés ‘decision’ is also aligned with this verb, as it does not appear as a separate word on the English side. Note that even if the English translation is make a decision, döntés on the Hungarian side is also usually aligned with make as well as with decision, because make only corresponds to hoz ‘bring’ only in this and a few other similar light verb constructions. In contrast, e.g. in the case of the compositional táskát hoz phrase ‘to bring a bag’, bring and bag are both present on the English side, so these are only aligned with their Hungarian equivalents. Finally, we have normalized and sorted the list of nouns collected for the Hungarian verbs, based on their frequency and their homogeneity regarding the given verb. We cut off the end of the resulting list (where only phrases having a compositional meaning were gathered). The algorithm generated 6531 candidate expressions for 309 verbs.

Originally, we planned to evaluate the algorithm using a list of light verb constructions\(^5\) (LVC’s) (Vincze, 2011) created from the syntacti-

\(^5\)The list contains 1524 items.
cally annotated monolingual Szeged Dependency Treebank (Vincze et al., 2010) and the English-Hungarian SzegedParallel corpus. However, we found that it would be a mistake to consider the original list gold standard. Only 83.6% of the expressions on the Szeged list met our criteria. For the rest, we found that there is nothing odd about asking a question concerning the nominal part of the supposed light verb construction. Finally, we manually evaluated the union of the original list and the entries returned by our algorithm (7538 items altogether). The original list had a recall of 32.2% of the true positives on the union of lists. The precision and recall values for our algorithm turned out to be P=28.6%, and R=84.2%. As a result, we managed to extend the list of Hungarian LVC’s and verbal idioms significantly compared to the original Szeged list. We extended our lexicon of argument frames with LVC’s and idioms on the list we obtained by manually adding other arguments along with their thematic roles.

7 Aligning argument frames to their occurrences in the corpus

The first step of the algorithm aligning the argument frames to their occurrences in the UD corpus is reading the source lexicon files containing the argument frame descriptions and checking them for syntactic errors. It generates the full argument frame description for each verb by applying an inheritance mechanism adding the argument frames belonging to the verb group to those pertaining only to the given verb.

Explicit and implicit constraints on the form of arguments (suffixes, postpositions etc.) implied by the thematic roles in argument frame descriptions are converted into constraints on features and dependency relations applied to the morphological and syntactic annotations in the UD corpus, respectively. We align the argument frames to the verbs and the heads of phrases attached to them in the corpus using these constraints. The thematic roles location (LOC), destination (DST) and source (SRC) cover noun phrases the head of which is marked with the suffixes and postpositions used to denote location, direction and source (Where?, Where to?, From where?) and adverbs having such meaning. The argument frames of many verbs contain the thematic role PATH, which can be replaced by any combination of destination, source and location passed by (VIA). For the sake of readability, case suffixes are represented by their underlying phonological form in the argument frame database. The alignment algorithm converts these descriptions into feature constraints that match the morphosyntactic descriptions in the UD corpus.

Hungarian is a ‘pro drop’ language, i.e. subject and singular object pronouns generally have an explicit phonological representation in sentences only if they are stressed (e.g. focused or in contrastive topic position). Subjects and objects having no surface realization are recovered in the alignment algorithm by introducing implicit pronouns and assigning the corresponding thematic role to them if the argument frame contains such arguments and there is no explicit subject or object in the given clause. For infinitives, gerunds and participles, verbal argument frames are matched by implicitly binding subjects and objects depending on the type of the construction, while the rest of the arguments are matched in the regular manner. Since objects (NP’s marked with accusative case) and infinitives can only occur as arguments, not as adjuncts, frames that do not contain an object/infinitive are discarded if an explicit object/infinitive is attached to the actual verb instance.

The lexically bound nominal element of some of the light verb constructions is an apparently possessive form (annotated as the head of the phrase like in other possessive structures), e.g. szomszédja nyakára küldte az adóhatóságot ‘he set the tax authority to check up on his neighbour’ (lit. ‘he sent the tax authority onto his neighbour’s neck’). In these constructions, the actual argument that is to be assigned a thematic role is not this semantically empty word, which rather functions like an oblique case ending or postposition, but the possessor (i.e. the neighbor in the previous example). These structures are converted into a form similar to postpositional phrases. The real argument (his neighbour) becomes the head in the modified structure, and thus the appropriate thematic role can be directly assigned to it.

When multiple frames match the specific verb instance, the most specific frame is selected: matching light verb or idiomatic constructions are ranked high, otherwise match candidates are ranked by the length of the matching argument list.

Figure 6 shows how the original annotation of a sentence in the original UD corpus was corrected
and extended with thematic role labels by the the
adjunct and verbal argument frame matching algo-

\section*{8 Conclusion}

Within the scope of the ongoing research pre-
sented in this article, we have created a seman-
tically rich corpus annotation for Hungarian us-
ing the Hungarian UD subcorpus as a starting
point. Our future tasks include integrating the ar-
gent frames of nominal predicates and manual
checking of the generated thematic role annota-
tion. We may also need to finetune the interac-
tion of lexically-driven automatic adjunct annota-
tion and verbal argument frame alignment, and the
ranking of matching argument frames. Further-
more, arguments annotated with thematic roles
will need to be semantically further subcatego-
rized to be able to generate the right questions. We
have done this, but we have not yet integrated this
information with the rest of the annotation. We
will also need to extend our corpus (converting and
correcting parts of the Szeged Dependency Tree-
bank not included in the Hungarian UD corpus)
to provide enough training material for a semantic
parser.

\section*{Acknowledgments}

This research has been implemented with support
provided by grants FK 125217 and PD 125216
of the National Research, Development and In-
novation Office of Hungary financed under the
FK 17 and PD 17 funding schemes as well as by
grant UNKP-18–3-III-PKKE-26 of the New Na-
tional Excellence Program of the Ministry of Hu-
man Resources. We would like to thank Kinga Fe-
gyó and Ivett Bognár for their participation in cre-
ating verbal argument frames and assigning the-
matic roles.
