Intersection theory of coassociative submanifolds in $G_2$-manifolds and Seiberg-Witten invariants

Naichung Conan Leung and Xiaowei Wang

November 18, 2018

Abstract

We study the problem of counting instantons with coassociative boundary condition in (almost) $G_2$-manifolds. This is analogous to the open Gromov-Witten theory for counting holomorphic curves with Lagrangian boundary condition in Calabi-Yau manifolds. We explain its relationship with the Seiberg-Witten invariants for coassociative submanifolds.

Intersection theory of Lagrangian submanifolds is an essential part of the symplectic geometry. By counting the number of holomorphic disks bounding intersecting Lagrangian submanifolds, Floer and others defined the celebrated Floer homology theory. It plays an important role in mirror symmetry for Calabi-Yau manifolds and string theory in physics. In M-theory, Calabi-Yau threefolds are replaced by seven dimensional $G_2$-manifolds $M$ (i.e. oriented Octonion manifolds [18]). The analog of holomorphic disks (resp. Lagrangian submanifolds) are instantons or associative submanifolds (resp. coassociative submanifolds or branes) in $M$ [17]. An important project is to count the number of instantons with coassociative boundary conditions. In particular we want to study the following problem.

Problem: Given two nearby coassociative submanifolds $C$ and $C'$ in a (almost) $G_2$-manifold $M$. Relate the number of instantons in $M$ bounding $C \cup C'$ to the Seiberg-Witten invariants of $C$.

The basic reason is a coassociative submanifold $C'$ which is infinitesimally close to $C$ corresponds to a symplectic form on $C$ which degenerates along $C \cap C'$. Instantons bounding $C \cup C'$ would become holomorphic curves on $C$ modulo bubbling. By the work of Taubes, we expect that the number of such instantons is given by the Seiberg-Witten invariant of $C$.

In this paper we treat the special case when $C$ and $C'$ are disjoint, i.e. $C$ is a symplectic four manifold. Recall that Taubes showed that the Seiberg-Witten invariants of such a $C$ is given by the Gromov-Witten invariants [24] of $C$. Our main result is following theorem.
Theorem 1 Suppose that $M$ is an (almost) $G_2$-manifold and $\{C_t\}$ is an one parameter family of coassociative submanifolds in $M$ such that $dC_t/dt|_{t=0}$ is nonvanishing.

If $\{A_t\}$ is any one parameter family of instantons in $M$ satisfying

$$\partial A_t \subset C_t \cup C_0 \text{ and } \lim_{t \to 0} A_t = \Sigma \text{ in } C^1\text{-topology},$$

then $\Sigma$ is a $J$-holomorphic curve in $C_0$.

Conversely, suppose that $\Sigma$ is a regular $J$-holomorphic curve in $C_0$, then it is the limit of a family of instantons $A_t$’s as described above.

A few remarks are in order: First, counting such small instantons is basically a problem in four manifold theory because of Bryant’s result which says that the zero section $C$ in $\Lambda^2_+ (C)$ is always a coassociative submanifold for some incomplete $G_2$-metric on its neighborhood provided that the bundle $\Lambda^2_+ (C)$ is topologically trivial. Second, when $C$ and $C'$ are not disjoint, the above theorem should still hold true. However using the present approach to prove it would require a good understanding of the Seiberg-Witten theory on any four manifold with a degenerated symplectic form as in Taubes program. Third, when $C$ and $C'$ are not close to each other then we have to take into account the bubbling phenomenon which has not been established yet. Nevertheless, one would expect that if the volume of $A_t$’s are small, then bubbling cannot occur, thus they would converge to a holomorphic curve in $C_0$.

1 Review of Symplectic Geometry

Given any symplectic manifold $(X, \omega)$ of dimension $2n$, there exists a compatible metric $g$ so that the equation

$$\omega(u, v) = g(Ju, v)$$

defines a Hermitian almost complex structure

$$J : T_X \to T_X,$$

that is $J^2 = -\text{id}$ and $g(Ju, Jv) = g(u, v)$.

A holomorphic curve, or instanton, is a two dimensional submanifold $\Sigma$ in $X$ whose tangent bundle is preserved by $J$. Equivalently $\Sigma$ is calibrated by $\omega$, i.e. $\omega|_{\Sigma} = \text{vol}_{\Sigma}$. By counting the number of instantons in $X$, one can define a highly nontrivial invariant for the symplectic structure on $X$, called the Gromov-Witten invariant.

When the instanton $\Sigma$ has nontrivial boundary, then the corresponding free boundary value problem would require $\partial \Sigma$ to lie on a Lagrangian submanifold $L$ in $X$, i.e. $\dim L = n$ and $\omega|_{L} = 0$. Floer studied the intersection theory of Lagrangian submanifolds and defined the Floer homology group $HF (L, L')$ under certain assumptions.
Suppose that $X$ is a Calabi-Yau manifold, i.e. the holonomy group of the Levi-Civita connection is inside $SU(n)$, equivalently $J$ is an integrable complex structure on $X$ and there exists a holomorphic volume form $\Omega_X \in \Omega^{n,0}(X)$ on $X$ satisfying $\Omega_X \bar{\Omega}_X = C^n \omega^n$. Under the mirror symmetry transformation, $HF(L,L')$ is expected to correspond to the Dolbeault cohomology group of coherent sheaves in the mirror Calabi-Yau manifold.

A Lagrangian submanifold $L$ in $X$ is called a special Lagrangian submanifold with phase zero (resp. $\pi/2$) if $\text{Im} \Omega_X|_L = 0$ (resp. $\text{Re} \Omega_X|_L = 0$). Such a $L$ is calibrated by $\text{Re} \Omega_X|_L$ (resp. $\text{Im} \Omega_X|_L$). They play important roles in the Strominger-Yau-Zaslow mirror conjecture for Calabi-Yau manifolds \cite{22}.

When $X$ is a Calabi-Yau threefold, there are conjectures of Vafa and others (e.g. \cite{2}\cite{9}) that relates the (partially defined) open Gromov-Witten invariant of the number of instantons with Lagrangian boundary condition to the large $N$ Chern-Simons invariants of knots in three manifolds.

2 Counting Instantons in (almost) $G_2$-manifolds

Notice that a real linear homomorphism $J : \mathbb{R}^m \rightarrow \mathbb{R}^m$ being a Hermitian complex structure on $\mathbb{R}^m$ is equivalent to the following conditions: for any vector $v \in \mathbb{R}^m$ we have (i) $Jv$ is perpendicular to both $v$ and (ii) $|Jv| = |v|$. We can generalize $J$ to involve more than one vector. We call a skew symmetric homomorphism
\[ \times : \mathbb{R}^m \otimes \mathbb{R}^m \rightarrow \mathbb{R}^m \]
a (2-fold) vector cross product if it satisfies
\[ \begin{align*}
(\text{i}) & \quad (u \times v) \text{ is perpendicular to both } u \text{ and } v, \\
(\text{ii}) & \quad |u \times v| = \text{Area of parallelogram spanned by } u \text{ and } v.
\end{align*} \]

The obvious example of this is the standard vector product on $\mathbb{R}^3$. By identifying $\mathbb{R}^3$ with $\text{Im } \mathbb{H}$, the imaginary part of the quaternion numbers, we have
\[ u \times v = \text{Im } uv. \]

The same formula defines a vector cross product on $\mathbb{R}^7 = \text{Im } \mathbb{O}$, the imaginary part of the octonion numbers. Brown and Gray \cite{10} showed that these two are the only possible vector cross product structures on $\mathbb{R}^m$ up to isomorphisms.

Suppose that $M$ is a seven dimensional Riemannian manifold with a vector cross product $\times$ on each of its tangent spaces. The analog of the symplectic form is a degree three differential form $\Omega$ on $M$ defined as follow:
\[ \Omega(u, v, w) = g(u \times v, w). \]

**Definition 2** Suppose that $(M, g)$ is a Riemannian manifold of dimension seven with a vector cross product $\times$ on its tangent bundle. Then (1) $M$ is called an almost $G_2$-manifold if $d\Omega = 0$ and (2) $M$ is called a $G_2$-manifold if $\nabla \Omega = 0$. 
It can be proven that the condition $\nabla \Omega = 0$ is equivalent to $\Omega$ being a harmonic form, i.e. $\Delta \Omega = 0$. Furthermore $M$ is a $G_2$-manifold if and only if its holonomy group is inside the exceptional Lie group $G_2 = \text{Aut}(\mathcal{D})$. The geometry of $G_2$-manifolds can be interpreted as the symplectic geometry on its knot space (see e.g. [17], [21]).

For example, if $(X, \omega_X)$ is a Calabi-Yau threefold with a holomorphic volume form $\Omega_X$, then the product manifold $M = X \times S^1$ is a $G_2$-manifold with

$$\Omega = \text{Re} \Omega_X + \omega_X \wedge d\theta.$$  

Next we define the analogs of holomorphic curves and Lagrangian submanifolds in the $G_2$ setting.

**Definition 3** Suppose that $A$ is a three dimensional submanifold of an almost $G_2$-manifold $M$. We call $A$ an **instanton** or **associative submanifold**, if $A$ is preserved by the vector cross product $\times$.

Harvey and Lawson [11] showed that $A \subset M$ is an instanton if and only if $A$ is calibrated by $\Omega$, i.e. $\Omega|_A = \text{vol}_A$.

In M-theory, associative submanifolds are also called $M2$-branes. For example when $M = X \times S^1$ with $X$ a Calabi-Yau threefold, $\Sigma \times S^1$ (resp. $L \times \{p\}$) is an instanton in $M$ if and only if $\Sigma$ (resp. $L$) is a holomorphic curve (resp. special Lagrangian submanifold with zero phase) in $X$.

A natural interesting question is to count the number of instantons in $M$. In the special case of $M = X \times S^1$, these numbers are reduced to the conjectural invariants proposed by Joyce [15] by counting special Lagrangian submanifolds in Calabi-Yau threefolds. This problem has been discussed by many physicists. For example Harvey and Moore discussed in [12] the mirror symmetry aspects of these invariants; Aganagic and Vafa in [2] related these invariants to the open Gromov-Witten invariants for local Calabi-Yau threefolds; Beasley and Witten argued in [3] that when there is a moduli of instantons, then one should count them using the Euler characteristic of the moduli space. In this paper we count the number of instantons with boundary lying on a coassociative submanifold in $M$. The compactness issues of the moduli of instantons is a very challenging problem because the dimension of an instanton is bigger than two. This makes it very difficult to define an honest invariant by counting instantons.

When an instanton $A$ has a nontrivial boundary, $\partial A \neq \phi$, one should require it to lie inside a **brane** or a **coassociative submanifold** [17], i.e. submanifolds in $M$ where the restriction of $\Omega$ is zero and have the largest possible dimension. Branes are the analog of Lagrangian submanifolds in symplectic geometry.

**Definition 4** Suppose that $C$ is a four dimensional submanifold of an almost $G_2$-manifold $M$. We call $C$ a **coassociative submanifold** if

$$\Omega|_C = 0 \text{ and } \dim C = 4.$$
For example when \( M = X \times S^1 \) with \( X \) a Calabi-Yau threefold, \( H \times S^1 \) (resp. \( C \times \{p\} \)) is a coassociative submanifold in \( M \) if and only if \( H \) (resp. \( C \)) is a special Lagrangian submanifold with phase \( \pi/2 \) (resp. complex surface) in \( X \). In [17] J.H. Lee and the first author showed that the isotropic knot space \( \hat{K}_S \cdot X \) of \( X \) admits a natural holomorphic symplectic structure. Moreover \( \hat{K}_S \cdot H \) (resp. \( \hat{K}_S \cdot C \)) is a complex Lagrangian submanifold in \( \hat{K}_S \cdot X \) with respect to the complex structure \( J \) (resp. \( K \)).

Constructing special Lagrangian submanifolds with zero phase in \( X \) with boundaries lying on \( H \) (resp. \( C \)) corresponds to the Dirichlet (resp. Neumann) free boundary value problem for minimizing volume among Lagrangian submanifolds as studied by Schoen and others. For a general \( G_2 \)-manifold \( M \), the natural free boundary value for an instanton is a coassociative submanifold. Similar to the intersection theory of Lagrangian submanifolds in symplectic manifolds.

We propose to study the following problem: Count the number of instantons in \( G_2 \)-manifolds bounding two coassociative submanifolds.

The product of a coassociative submanifold with a two dimensional plane inside the eleven dimension spacetime \( M \times \mathbb{R}^{3,1} \) is called a \( D5 \)-brane in M-theory. Counting the number of M2-branes between two D5-branes has also been studied in the physics literatures.

In general this is a very difficult problem. For instance, counting \( S^1 \)-invariant instantons in \( M = X \times S^1 \) is the open Gromov-Witten invariants. However when the two coassociative submanifolds \( C \) and \( C' \) are close to each other, we can relate the number of instantons between them to the Seiberg-Witten invariant of \( C \).

### 3 Relationships to Seiberg-Witten invariants

To determine the number of instantons between nearby coassociative submanifolds, we first recall the deformation theory of coassociative submanifolds \( C \) inside any \( G_2 \)-manifold \( M \), as developed by McLean [20]. Given any normal vector \( v \in N_{C/M} \), the interior product \( \iota_v \Omega \) is naturally a self-dual two form on \( C \) because of \( \Omega|_C = 0 \). This gives a natural identification,

\[ N_{C/M} \overset{\cong}{\rightarrow} \Lambda_+^2 (C) \]

\[ v \mapsto \eta_0 = \iota_v \Omega. \]

Furthermore infinitesimal deformations of coassociative submanifolds are parametrized by self-dual harmonic two forms \( \eta_0 \in H_+^2 (C) \), and they are always unobstructed. Notice that the zero set of \( \eta_0 \) is the intersection of \( C \) with a infinitesimally near coassociative submanifold, that is

\[ \{ \eta_0 = 0 \} = \lim_{t \to 0} (C \cap C_t), \]

where \( C = C_0 \) and \( \eta_0 = dC_t / dt |_{t=0} \).

Since

\[ \eta_0 \wedge \eta_0 = \eta_0 \wedge * \eta_0 = |\eta_0|^2 * 1, \]

5
η₀ defines a natural symplectic structure on \( C^{\text{reg}} := C \setminus \{ \eta_0 = 0 \} \). If we normalize \( \eta_0 \),
\[ \eta = \eta_0 / |\eta_0|, \]
then the equation
\[ \eta(u, v) = g(Ju, v) \]
defines a Hermitian almost complex structure on \( C^{\text{reg}} \).

The next lemma says that when two coassociative submanifolds \( C \) and \( C' \) come together, then the limit of instantons bounding them will be a holomorphic curve \( \Sigma \) in \( C^{\text{reg}} \) with boundary \( C \cap C' \).

**Proposition 5** Suppose that \( C_t \) is an one parameter family of coassociative submanifolds in a \( G_2 \)-manifold \( M \). Suppose that \( A_t \) is a family of instantons in \( M \) bounding \( C_0 \cup C_t \) for nonzero \( t \) and
\[ \lim_{t \to 0} A_t = \Sigma \]
exists in \( C^1 \)-topology. Then \( \Sigma \) is a \( J \)-holomorphic curve in \( C_0^{\text{reg}} \) with boundary \( C_0 \setminus C_0^{\text{reg}} \).

**Proof.** For simplicity we assume that \( \eta_0 = dC_t / dt|_{t=0} \) is nowhere vanishing. Let us denote the boundary component of \( A_t \) in \( C_0 \) as \( \Sigma_t \) and the unit normal vector field for \( \Sigma_t \) in \( A_t \) as \( n_t \). Note that \( n_t \) is perpendicular to \( C_0 \). This is because \( A_t \) being preserved by the vector cross product implies that
\[ n_t = u \times v, \]
for some tangent vectors \( u \) and \( v \) in \( \Sigma_t \), therefore given any tangent vector \( w \) along \( C_0 \), we have
\[ g(n_t, w) = g(u \times v, w) = \Omega(u, v, w) = 0. \]
The last equality follows from \( C_0 \) being coassociative and \( \Sigma_t \subset C_0 \). Using this and the fact that \( A_t \) bounds \( C_0 \cup C_t \) with \( \lim_{t \to 0} C_t = C_0 \), i.e. \( n_t \) is pointing towards \( C_t \), we obtain
\[ \lim_{t \to 0} n_t = \eta|_{\Sigma}. \]
Therefore \( \Sigma = \lim_{t \to 0} \Sigma_t \) is a holomorphic curve in \( C_0 \) with respect to the almost complex structure \( J \) defined by \( \eta(u, v) = g(Ju, v) \). \( \blacksquare \)

The reverse of the above proposition should also hold true. The Lagrangian analog of it is proven by Fukaya and Oh in [6]. On the other hand, by the celebrated work of Taubes, we expect that the number of such open holomorphic curves in \( C_0 \) equals to the Seiberg-Witten invariant of \( C_0 \). We conjecture the following statement.
Conjecture: Suppose that $C$ and $C'$ are nearby coassociative submanifolds in a $G_2$-manifold $M$. Then the number of instantons in $M$ with small volume and with boundary lying on $C \cup C'$ is given by the Seiberg-Witten invariants of $C$.

In the next section we will discuss the case when $C$ and $C'$ do not intersect. The basic ideas are (i) the limit of such instantons is a holomorphic curve with respect to the (degenerated) symplectic form $\eta$ on $C$ coming from its deformations as coassociative submanifolds and this process can be reversed; (ii) the number of holomorphic curves in the four manifold $C$ should be related to the Seiberg-Witten invariant of $C$ by the work of Taubes (24, 25).

Suppose that $\eta$ is a self-dual two form on $C$ with constant length $\sqrt{2}$, in particular it is a (non-degenerate) symplectic form, and $\Sigma$ is a holomorphic curve in $C$, possibly disconnected. If $\Sigma$ is regular in the sense that the linearized operator $\bar{\partial}$ has trivial cokernel [23], then Taubes showed that the perturbed Seiberg-Witten equations,

$$F_a^+ = \tau (\psi \otimes \psi^*) - r\sqrt{-1}\eta,$$
$$D_{A(a)}\psi = 0,$$

have solutions for all sufficient large $r$. Here $a$ is a connection on the complex line bundle $E$ over $C$ whose first Chern class equals the Poincaré dual of $\Sigma$, $PD[\Sigma]$, $\psi$ is a section of the twisted spinor bundle $S_+ = E \oplus (K^{-1} \otimes E)$ and $D_{A(a)}$ is the twisted Dirac operator. The number of such solutions is the Seiberg-Witten invariant $SW_C(\Sigma)$ of $C$. Furthermore the converse is also true, thus Taubes established an equivalence between Seiberg-Witten theory and Gromov-Witten theory for symplectic four manifolds. This result has far reaching applications in four dimensional symplectic geometry.

For a general four manifold $C$ with nonzero $b^+(C)$, using a generic metric, any self-dual two form $\eta$ on $C$ defines a degenerate symplectic form on $C$, i.e. $\eta$ is a symplectic form on the complement of $\{\eta = 0\}$, which is a finite union of circles (see [S14]). Therefore, one might expect to have a relationship between the Seiberg-Witten of $C$ and the number of holomorphic curves with boundaries $\{\eta = 0\}$ in $C$. Part of this Taubes’ program has been verified in [24, 25].

4 Proof of the main theorem

Suppose that $\eta$ is a nowhere vanishing self-dual harmonic two form on a coassociative submanifold $C$ in a $G_2$-manifold $M$. For any holomorphic curve $\Sigma$ in $C$, we want to construct an instanton in $M$ bounding $C$ and $C'$, where $C'$ is a small deformation of the coassociative submanifold $C$ along the normal direction $\eta$. Notice that $C$ and $C'$ do not intersect. We will construct such an instanton using a perturbation argument which requires a lower bound on the first eigenvalue for the appropriate elliptic operator. Recall that the deformation of an instanton is governed by a twisted Dirac operator. We will reinterpret it as a complexified version of the Cauchy-Riemann operator.
4.1 Deformation of instantons

To construct an instanton $A$ in $M$ from a holomorphic curve $\Sigma$ in $C$, we need to perturb an almost instanton $A'$ to a honest one using a quantitative version of the implicit function theorem. Let us first recall the deformation theory of instantons $A$ ([11] and [17]) in a Riemannian manifold $M$ with a parallel (or closed) $r$-fold vector cross product

$$\times : \Lambda^r T_M \to T_M.$$ 

In our situation, we have $r = 2$. By taking the wedge product with $T_M$ we obtain a homomorphism

$$\tau : \Lambda^{r+1} T_M \to \Lambda^2 T_M \cong \Lambda^2 T_M^*,$$

where the last isomorphism is induced from the Riemannian metric. As a matter of fact, the image of $\tau$ lies inside the subbundle $g_M^\perp M$ which is the orthogonal complement of $g_M \subset \text{so}(T_M) \cong \Lambda^2 T_M^*$, the bundle infinitesimal isometries of $T_M$ preserving $\times$. That is,

$$\tau \in \Omega^{r+1}(M, g_M^\perp).$$

Lemma 6 ([11], [17]) An $r + 1$ dimensional submanifold $A \subset M$ is an instanton, i.e. preserved by $\times$, if and only if

$$\tau|_A = 0 \in \Omega^{r+1}(A, g_M^\perp).$$

This lemma is important in describing deformations of an instanton. Namely it shows that the normal bundle to an instanton $A$ is a twisted spinor bundle over $A$ and infinitesimal deformations of $A$ are parametrized by twisted harmonic spinors.

In our present situation, $M$ is a $G_2$-manifold. Using the interior product with $\Omega$, we can identify $g_M^\perp$ with the tangent bundle $T_M$ and we can also characterize $\tau \in \Omega^3(M, T_M)$ by the following formula,

$$(*\Omega) (u, v, w, z) = g(\tau(u, v, w), z).$$

Therefore $A \subset M$ is an instanton if and only if $*(\tau|_A) = 0 \in T_M|_A$. As a matter of fact, if $A$ is already close to be an instanton, then we only need the normal components of $*(\tau|_A)$ to vanish.

Proposition 7 There is a positive constant $\delta$ such that for any three dimensional linear subspace $A$ in $M \cong \text{Im } \Omega$ with $|\tau|_A| < \delta$, $A$ is an instanton if and only if $*(\tau|_A) \in T_A$. 

Proof. McLean [20] observed that if $A_t$ is a family of linear subspaces in $M \cong \mathbb{R}^7$ with $A_0$ an instanton, then

$$*\left(\frac{d\tau}{dt}|_{A_t}\right)|_{t=0} \in N_{A_0/M} \subset T_M|_{A_0}.$$
Explicitly, if we denote the standard base for $\mathbb{R}^7$ as $e_i$'s, e.g. $e_1 \times e_2 = e_3$, then we can assume that $A$ is spanned by $e_1, e_2$ and $\hat{e}_3 = e_3 + \sum_{i=4}^{7} t_i e_i$ for some small $t_i$'s because the natural action of $G_2$ on the Grassmannian $Gr(2, 7)$ is transitive. Then an easy computation shows that the normal component of $\ast(\tau|_A)$ in $N_{A/M}$ is given by

$$\ast(\tau|_A)^\perp = -t_5 (e_4)^\perp + t_4 (e_5)^\perp + t_7 (e_6)^\perp - t_6 (e_7)^\perp.$$ 

When $t_j$'s are all zero, we have $(e_j)^\perp = e_j$ for $4 \leq j \leq 7$. In particular, they are linearly independent when $t_j$'s are small. In that case, $\ast(\tau|_A)^\perp = 0$ will actually imply that $t_j = 0$ for all $j$, i.e. $A$ is an instanton in $M$. Hence the proposition. 

This proposition will be needed later when we perturb an almost instanton to an honest one. We also need to identify the normal bundle $N_{A/M}$ to an instanton $A$ with a twisted spinor bundle over $A$ as follows: We denote $P$ the $SO(4)$-frame bundle of $N_{A/M}$. Using the identification $$SO(4) = Sp(1)Sp(1) \to SO(\mathbb{H}),$$ $(p, q) \cdot y = p y \bar{q}$, the tangent bundle to $A$ can be identified as an associated bundle to $P$ for the representation $SO(4) \to SO(Im H), (p, q) \cdot y = qy \bar{q}$. As a result the spinor bundle $\mathcal{S}$ of $A$ is associated to the representation $SO(4) \to SO(\mathbb{H})$ given by $(p, q) \cdot y = y \bar{q}$. Hence we obtain

$$N_{A/M} \cong \mathcal{S} \otimes_{\mathbb{H}} E,$$

where $E$ is the associated bundle to $P$ for the representation $SO(4) \to SO(\mathbb{H})$ given by $(p, q) \cdot y = py$.

### 4.2 Complexified Cauchy-Riemann equation

Recall that the normal bundle to any instanton $A$ is a twisted spinor bundle $\mathcal{S} \otimes_{\mathbb{H}} E$, or simply $\mathcal{S}$, over $A$. Let $\mathcal{D}$ be the Dirac operator on $A$. If $V := V^a \frac{\partial}{\partial x^a}$ is a normal vector field to $A$ and we write the covariant differentiation of $V$ as $\nabla(V) := V^a \frac{\partial}{\partial x^a} \otimes \omega^i$, then by viewing $V$ as a twisted spinor or a quaternion valued function on $A$,

$$V = V^4 + iV^5 + jV^6 + kV^7,$$

we have,

$$\mathcal{D}V = - \left( V^5 \bar{V}_2^6 + V^6 \bar{V}_3^7 \right) + i \left( V^4 \bar{V}_1^6 + V^6 \bar{V}_3^7 \right) + j \left( V^4 \bar{V}_2^5 + V^5 \bar{V}_1^7 \right) + k \left( V^4 \bar{V}_3^5 + V^5 \bar{V}_2^7 \right),$$

where $\mathcal{D} := \nabla_1 i + \nabla_2 j + \nabla_3 k$. 

9
Let us first consider a simplified model, suppose that $A$ is a product Riemannian three manifold $[0, \varepsilon] \times \Sigma$ with coordinates $(x_1, z)$ where $z = x_2 + ix_3$. Let $e_1$ be the unit tangent vector field on $A$ normal to $\Sigma$, namely along the $x_1$-direction. We have

$$D = e_1 \cdot \frac{\partial}{\partial x_1} + \bar{\partial},$$

where $\bar{\partial}$ is the Dolbeault operator on the Riemann surface $\Sigma$.

The Clifford multiplication of $e_1$ on $S$ satisfies $e_1^2 = -1$ and therefore we have an eigenspace decomposition $S := S^+ \oplus S^-$ corresponding to eigenvalues $\pm i$.

If we write $V = (u, v)$ with $u = V^4 + iV^5 \in S^+$ and $v = V^6 + iV^7 \in S^-$, then we have

$$DV = \left( \frac{\partial u}{\partial x_1} i - \partial_z v \right) + \left( -\frac{\partial v}{\partial x_1} i + \bar{\partial}_z u \right) \cdot j$$

$$= \left( \frac{\partial u}{\partial x_1} + i\partial_z v \right) + \left( \frac{\partial v}{\partial x_1} + i\bar{\partial}_z u \right) \cdot j \cdot i$$

$$= \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix} \left( \frac{\partial}{\partial x_1} + \begin{bmatrix} 0 & i\partial_z \\ i\bar{\partial}_z & 0 \end{bmatrix} \right) \begin{bmatrix} u \\ v \end{bmatrix},$$

where

$$\partial_z := \frac{\partial}{\partial x_2} + i \frac{\partial}{\partial x_3} \quad \text{and} \quad \bar{\partial}_z := \frac{\partial}{\partial x_2} - i \frac{\partial}{\partial x_3}.$$ 

We will also denote $i\partial_z$ and $i\bar{\partial}_z$ by $\partial^+$ and $\partial^-$ respectively. They are Dirac operators on $\Sigma$ and they satisfy

$$\partial^+ = (\partial^-)^*. $$

This implies that the Dirac equation $DV = 0$ is equivalent to the following complexified Cauchy-Riemann equations,

$$\bar{\partial}_z u = \frac{\partial v}{\partial x_1} i,$$

$$\partial_z v = \frac{\partial u}{\partial x_1} i.$$

### 4.3 Eigenvalue estimates

In this subsection we give a quantitative estimate of the eigenvalue of the linearized operator for the above simplified model. To do so, we first introduce the following function spaces for spinors $V = (u, v)$ over a product three manifold $A_\varepsilon = [0, \varepsilon] \times \Sigma$.

**Definition 8**
Suppose that $\mathcal{S}$ is the spinor bundle over a product three manifold $A_{\varepsilon} = [0,\varepsilon] \times \Sigma$. We define function spaces

$$H^m_{-}\left( A_{\varepsilon} \right) := \{ V \in H^m\left( A_{\varepsilon}, \mathcal{S} \right) | \ v|_{\{0\} \times \Sigma} = v|_{\{\varepsilon\} \times \Sigma} = 0 \}$$

and

$$H^m_{+}\left( A_{\varepsilon} \right) := \{ V \in H^m\left( A_{\varepsilon}, \mathcal{S} \right) | \ u|_{\{0\} \times \Sigma} = u|_{\{\varepsilon\} \times \Sigma} = 0 \}$$

where $H^m\left( A, \mathcal{S} \right)$ is $m$-th Sobolev space of sections of $\mathcal{S}$.

It is well known (see for instance [5] Theorem 21.5) that the Dirac operators $D_{\pm} := D|_{H^1_{-}\left( A_{\varepsilon}, \mathcal{S} \right)} : H^1_{\pm}\left( A_{\varepsilon}, \mathcal{S} \right) \to L^2\left( A_{\varepsilon}, \mathcal{S} \right)$ give well-defined local elliptic boundary problems and the formal adjoint $D_{\ast} = D_{-}$. We are going to obtain an estimate for its first eigenvalue.

**Theorem 9** Suppose $\lambda_{\partial^+}$ is the first eigenvalue of $\Delta_{\Sigma} = \partial^- \partial^+$ in the space $H^1\left( \Sigma, \mathcal{S}^+ \right)$ and let

$$\lambda_D := \inf_{V \in H^1_{-}\left( A_{\varepsilon}, \mathcal{S} \right)} \frac{\int_X \|DV\|^2}{\int_X \|V\|^2}.$$ 

Then

$$\lambda_{\partial^+} \geq \lambda_D \geq \min\{\lambda_{\partial^+}, 2/\varepsilon^2\}.$$ 

In particular, we have $\lambda_D = \lambda_{\partial^+}$ for small $\varepsilon$.

**Proof.** For $\forall V = (u, v) \in H^1_{-}\left( A_{\varepsilon} \right)$ we have

$$\langle DV, DV \rangle_{L^2} = \int_{[0,\varepsilon] \times \Sigma} \left\langle \frac{\partial V}{\partial x_1}, \left[ \begin{array}{cc} 0 & \partial^+ \\ \partial^- & 0 \end{array} \right] V \right\rangle + \|\partial^- v\|^2 + \|\partial^+ u\|^2.$$ 

Using the formula $\partial^+ = (\partial^+)^\ast$, we have

\[\begin{align*}
\int_{[0,\varepsilon] \times \Sigma} &\left\langle \frac{\partial V}{\partial x_1}, \left[ \begin{array}{cc} 0 & \partial^+ \\ \partial^- & 0 \end{array} \right] V \right\rangle \\
&= \int_{[0,\varepsilon] \times \Sigma} \left\langle \frac{\partial u}{\partial x_1}, \partial^+ v \right\rangle + \left\langle \frac{\partial v}{\partial x_1}, \partial^- u \right\rangle \\
&= \int_{[0,\varepsilon] \times \Sigma} \left\langle \partial^- \left( \frac{\partial u}{\partial x_1} \right), v \right\rangle - \left\langle v, \partial^- \left( \frac{\partial u}{\partial x_1} \right) \right\rangle + \int_{\{\varepsilon\} \times \Sigma} \left\langle v, \partial^- u \right\rangle - \int_{\{0\} \times \Sigma} \left\langle v, \partial^- u \right\rangle \\
&= 0.
\end{align*}\]
In order to estimate \( \int_A |V_{x_1}|^2 \), we notice that, for any fixed point \( p \in \Sigma \), \( v|_{[0, \varepsilon] \times \{p\}} \) can be treated as a function over the interval \([0, \varepsilon]\) and we compute,

\[
\int_0^\varepsilon v^2 \, dx_1 = \int_0^\varepsilon \left( \int_0^{x_1} \frac{\partial v}{\partial x_1} (t) \, dt \right)^2 \, dx_1
\]

\[
\leq \int_0^\varepsilon \left( \int_0^{x_1} ds \right) \left( \int_0^{x_1} \left| \frac{\partial v}{\partial x_1} (t) \right|^2 \, dt \right) \, dx_1
\]

\[
\leq \int_0^\varepsilon x_1 \, dx_1 \int_0^\varepsilon \left| \frac{\partial v}{\partial x_1} (t) \right|^2 \, dt
\]

\[
= \frac{\varepsilon^2}{2} \int_0^\varepsilon \left| \frac{\partial v}{\partial x_1} (t) \right|^2 \, dt.
\]

This is basically an effective Poincaré inequality. By putting all these together, we have

\[
\langle DV, DV \rangle_{L^2} = \int_{[0, \varepsilon] \times \Sigma} \left( \|u_x\|^2 + \|v_x\|^2 + \|\partial^- v\|^2 + \|\partial^+ u\|^2 \right)
\]

\[
\geq \int_0^\varepsilon \int_\Sigma \|\partial^+ u\|^2 + \int_0^\varepsilon \int_\Sigma \|v_x\|^2
\]

\[
\geq \lambda_{\partial^+} \int_0^\varepsilon \int_\Sigma \|u\|^2 + \frac{2}{\varepsilon^2} \int_\Sigma \int_0^\varepsilon \|v\|^2
\]

\[
\geq \min \left\{ \lambda_{\partial^+}, 2/\varepsilon^2 \right\} \left( \int_0^\varepsilon \int_\Sigma \|u\|^2 + \int_\Sigma \int_0^\varepsilon \|v\|^2 \right)
\]

\[
= \min \left\{ \lambda_{\partial^+}, 2/\varepsilon^2 \right\} \|V\|^2_{L^2}.
\]

Therefore

\[
\lambda_D \geq \min \left\{ \lambda_{\partial^+}, 2/\varepsilon^2 \right\}.
\]

Conversely, we suppose \( u \) is the first eigenfunction of \( \Delta_{\Sigma} = \partial^- \partial^+ \), we extend \( u \) trivially to a function on \([0, \varepsilon] \times \Sigma\) and define \( V := (u, 0) \in H^1 \) then we have

\[
\lambda_{\partial^+} \|V\|^2_{L^2} = \lambda_{\partial^+} \int_0^\varepsilon \int_\Sigma \|u\|^2
\]

\[
= \int_0^\varepsilon \int_\Sigma \|\partial^+ u\|^2
\]

\[
= \langle DV, DV \rangle_{L^2}
\]

\[
\geq \lambda_D \|V\|^2_{L^2}.
\]

Combining these, we have the theorem. ■

In order to adapt the simplified model above to our situation, let us consider \( D_g \) be the Dirac operator on a Riemannian Spin manifold \((A, g)\) with metric \( g \). If
we change the metric conformally \( g \rightarrow hg \) by any positive function \( h \in C^\infty (A) \) then we have
\[
\mathcal{D}_{hg} = h^{\frac{n+1}{n}} \circ \mathcal{D}_g \circ h^{-\frac{n-1}{n}},
\]
where \( n \) is the dimension of \( A \). If we compare the Rayleigh quotient we find
\[
\frac{1}{C} \inf_{V \in \mathcal{S}} \int_X \| \mathcal{D}_{hg} V \|_{hg}^2 \leq \inf_{V \in \mathcal{S}} \int_X \| \mathcal{D}_g V \|_g^2 \leq C \inf_{V \in \mathcal{S}} \int_X \| \mathcal{D}_{hg} V \|_{hg}^2,
\]
where \( C > 0 \) is a constant depending only on \( 0 < \min_{x \in A} h(x) \leq \max_{x \in A} h(x) < \infty \). In particular, this implies
\[
\frac{1}{C} \lambda_{\mathcal{D}_g} \leq \lambda_{\mathcal{D}_{hg}} \leq C \lambda_{\mathcal{D}_g}.
\]

Now we can extend the above Theorem to any product three manifold \( A = [0, \varepsilon] \times \Sigma \) with a warped product metric
\[
g_{A_\varepsilon} = h(x) \, dx_1^2 + g_\Sigma.
\]
This is because \( g_{A_\varepsilon} \) is conformally equivalent to a product metric \( dx_1^2 + h^{-1}g_\Sigma \) with conformal factor \( h(x) \). Therefore we have the following corollary.

**Corollary 10** Suppose \( A_\varepsilon = [0, \varepsilon] \times \Sigma \) is equipped with a Riemannian metric of the form \( g_{A_\varepsilon} = h(x) \, dx_1^2 + g_\Sigma \) for some smooth positive function \( h \) on \( \Sigma \). Then we have
\[
\frac{1}{C} \lambda_{\partial^+} \leq \lambda_{\mathcal{D}} \leq C \lambda_{\partial^+}
\]
with some constant \( C \) depend on \( h \).

In particular we have the following corollary.

**Corollary 11** Assumptions as before, we have \( \ker \partial^+ = 0 \) if and only if \( \ker \mathcal{D} = 0 \).

Remark: The above theorem gives an effective lower bound of the first eigenvalue of \( \mathcal{D}^+ \mathcal{D} \). If we only need to obtain the corollary we can also achieve this by exploring the complexified version of the Cauchy-Riemann equations as follows
\[
\frac{\partial}{\partial x_1} \left( \frac{\partial u}{\partial x_1} + \frac{\partial v}{\partial \bar{x}_1} \right) = \frac{\partial}{\partial x_1} \left( \bar{\partial}_z u \right)
\]
\[
= \bar{\partial}_z \left( \frac{\partial}{\partial x_1} u \right) = \bar{\partial}_z \left( -i \partial_z v \right)
\]
\[
= -i \Delta v,
\]
and
\[
\frac{\partial}{\partial x_1} \left( \frac{\partial u}{\partial x_1} - \frac{\partial v}{\partial \bar{x}_1} \right) = \frac{\partial}{\partial x_1} \left( \partial_z v \right)
\]
\[
= \partial_z \left( \frac{\partial}{\partial x_1} v \right) = \partial_z \left( -i \partial_z u \right)
\]
\[
= -i \Delta u.
\]
Therefore we have
\[
\left( \frac{\partial^2}{\partial x_1^2} + \Delta^\Sigma \right) u = 0; \quad \left( \frac{\partial^2}{\partial x_1^2} + \Delta^\Sigma \right) v = 0.
\]
We perform the Fourier transformation on $\Sigma$, and we obtain
\[
\left( \frac{\partial^2}{\partial x_1^2} - |\xi|^2 \right) \hat{v} = 0
\]
subjected to the boundary conditions, $\hat{v}|_{x_1=0} = \hat{v}|_{x_1=\varepsilon} = 0$. Clearly this implies $v = 0$ and therefore
\[
\frac{\partial u}{\partial x_1} = \bar{\partial} u = 0.
\]
That is $u \in \ker \bar{\partial}_z$.

### 4.4 Perturbation arguments

Let $C \subset M$ be a coassociative submanifold. Suppose that $v$ is a normal vector field on $C$ such that its corresponding self-dual two form, $\eta_0 = \iota_v \Omega \in \wedge^2_+(C)$ is harmonic with respect to the induced metric. So $\eta_0$ is actually a symplectic form on the complement of the zero set $Z(\eta_0)$ of $\eta_0$ in $C$. Furthermore $v$ defines an almost complex structure $J_v$ on the $C\setminus Z(\eta_0)$ via $|v|^{-1} v \times \cdot$. Since the deformation of coassociative manifold is unobstructed, we may assume that there is an one parameter family of coassociative submanifolds $C_t$ in $M$ which corresponds to integrating out the normal vector field $v$, that is
\[
\frac{dC_t}{dt} \big|_{t=0} = v \in \Gamma \left( C_0, N_{C_0/M} \right).
\]

In this article we assume that $\eta_0$ is nowhere vanishing on $C$, that is $(C, \eta_0)$ is a symplectic four manifold. We are going to establish a relation between the non-vanishing of Seiberg-Witten invariants of $C$ and the existence of instantons with coassociative boundary conditions.

Given any submanifold $\Sigma$ in $C$, using the variation normal vector fields $dC_t/dt$ to identify various $C_t$’s, we obtain submanifolds $\Sigma_t$ in $C_t$ vary smoothly with respect to $t$. We denote
\[
A'_\varepsilon := \bigcup_{0 \leq t \leq \varepsilon} \Sigma_t
\]
Since $\eta$ is nonvanishing on $C$, all coassociative submanifolds $C_t$’s are mutually disjoint. In particular $A'_\varepsilon$ is a smooth three dimensional submanifold in $M$. Suppose that $\Sigma \subset C$ is a $J_v$-holomorphic curve, then the tangent spaces of $A'_\varepsilon$ is associative along $\Sigma$. In fact $A'_\varepsilon$ is close to be an instanton when $\varepsilon$ is small, more precisely we have the following:

1. $|\tau|_{A'_\varepsilon} \leq c_1 \varepsilon$, for some constant $c_1$. 

14
(ii) The natural diffeomorphism between $A'_{\varepsilon}$ and $\Sigma \times [0, \varepsilon]$ is a $\varepsilon$-isometry between the induced metric $g_{A'_{\varepsilon}}$ on $A'_{\varepsilon}$ and the warped product metric

$$g_{\Sigma} + h(x) \, dt^2$$

on $\Sigma \times [0, \varepsilon]$, where $g_{\Sigma}$ is the induced metric on $\Sigma$ and $h(x)$ is the length of $v = dC_t/dt|_{t=0}$ restricted to $\Sigma$.

(iii) The derivative $F'(0)$ of the functional

$$F : \Gamma (A_{\varepsilon}, N_{A_{\varepsilon}/M}) \rightarrow \Gamma (A_{\varepsilon}, N_{A_{\varepsilon}/M})$$

is $\varepsilon$-close to the twisted Dirac operator on $A_{\varepsilon}$ with respect to the above warped product metric. That is,

$$F'(0) : H^1 (N_{A'_{\varepsilon}/M}) \rightarrow L^2 (N_{A'_{\varepsilon}/M}) \quad \text{and} \quad |F'(0) - D_{\Sigma \times [0, \varepsilon]}|_{C^0} \leq c_2 \varepsilon,$$

for some constant $c_2$. Note that we need to use the orthogonal projection to identify the normal bundle to $A'_{\varepsilon}$ to the twisted spinor bundle of $\Sigma \times [0, \varepsilon]$.

These imply that $|\lambda (F'(0)) - \lambda (D)| \leq \frac{1}{2} \lambda (D)$ for $\varepsilon < \delta$ where $\delta$ is some small positive number depend on the geometry of $C_0$. Recall from proposition 7 that $F(V) = 0$ implies that the image of the exponential map $A = \exp_V (A_{\varepsilon})$ is an instanton in $M$. To find the zeros of $F$, we are going to apply the following quantitative version of the implicit function theorem.

**Theorem 12** Let $X$ and $Y$ be Banach space and $F : B_r (x_0) \subset X \rightarrow Y$ a $C^1$-map, such that

1. $(DF(x_0))^{-1}$ is a bounded linear operator with $| (DF(x_0))^{-1} F(x_0) | \leq \alpha$
   and $| (DF(x_0))^{-1} | \leq \beta$;

2. $|DF(x_1) - DF(x_2)| \leq k|x_1 - x_2|$ for all $x_1, x_2 \in B_r (x_0)$;

3. $2k\alpha\beta < 1$ and $2\alpha < r$.

Then $F$ has a unique zero $z$ in $B_r (x_0)$.

By combining with the eigenvalue estimates in section 4.3, we can obtain the following result on the existence of instantons.

**Theorem 13** Suppose that $M$ is a $G_2$-manifold and $C_t$ is an one parameter family of coassociative submanifolds in $M$ with $(dC_t/dt)|_{t=0}$ nonvanishing.

For any regular $J$-holomorphic curve $\Sigma$ in $C_0$, there is an instanton $A_{\varepsilon}$ in $M$ which is diffeomorphic to $[0, 1] \times \Sigma$ and $\partial A_{\varepsilon} \subset C_0 \cup C_{\varepsilon}$, for all sufficiently small positive $\varepsilon$. 

15
Proof. Consider the functional \( F_\varepsilon : X \to Y \) with \( X = H^1 (N_{A_\varepsilon} / M, Y = L^2 (N_{A_\varepsilon} / M) \) and \( F_\varepsilon (V) = \ast (\exp V \ast \tau)^\perp \). In order to apply the above implicit function theorem, we need to know that

\[
\left| (DF_\varepsilon (0))^{-1} F_\varepsilon (0) \right| \leq \alpha.
\]

From Theorem 9 and its Corollary 10 we know that for \( \varepsilon \) small we have

\[
\left| (DF_\varepsilon (0))^{-1} \right| \leq C \sqrt{2 \lambda_\partial}
\]

Also by our construction we have

\[
\lim_{\varepsilon \to 0} F_\varepsilon (0) = 0
\]

so for \( \varepsilon \) small, we have

\[
\lim_{\varepsilon \to 0} \left| (DF_\varepsilon (0))^{-1} F_\varepsilon (0) \right| = 0.
\]

By applying the above implicit function theorem and proposition 7 we obtain an one parameter family of instantons \( A_\varepsilon \) for \( \varepsilon \) small, and \( \partial A_\varepsilon \subset C_0 \cup C_t \).

In particular, by combining Taubes’ results with the above theorem we obtain the following existence result.

Corollary 14 Suppose that \( C \) is a coassociative submanifold in a \( G_2 \)-manifold \( M \) with non-trivial Seiberg-Witten invariants. Given any symplectic form on \( C \), we write \( C_t \)’s the corresponding coassociative deformations of \( C \) in \( M \). Then there is an instanton \( A_t \) in \( M \) with boundaries lying on \( C_0 \cup C_t \) for each sufficiently small \( t \).

Lastly we expect that any instanton \( A \) in \( M \) bounding \( C_0 \cup C_t \) and with small volume must arise in the above manner. Namely we need to prove a \( \varepsilon \)-regularity result for instantons.
