Herbal medicine for the management of polycystic ovary syndrome (PCOS) and associated oligo/amenorrhoea and hyperandrogenism; a review of the laboratory evidence for effects with corroborative clinical findings

Susan Arentz1*, Jason Anthony Abbott2, Caroline Anne Smith3 and Alan Bensoussan3

Abstract

Background: Polycystic ovary syndrome (PCOS) is a prevalent, complex endocrine disorder characterised by polycystic ovaries, chronic anovulation and hyperandrogenism leading to symptoms of irregular menstrual cycles, hirsutism, acne and infertility. Evidence based medical management emphasises a multidisciplinary approach for PCOS, as conventional pharmaceutical treatment addresses single symptoms, may be contra-indicated, is often associated with side effects and not effective in some cases. In addition women with PCOS have expressed a strong desire for alternative treatments. This review examines the reproductive endocrine effects in PCOS for an alternative treatment, herbal medicine. The aim of this review was to identify consistent evidence from both pre-clinical and clinical research, to add to the evidence base for herbal medicine in PCOS (and associated oligo/amenorrhoea and hyperandrogenism) and to inform herbal selection in the provision clinical care for these common conditions.

Methods: We undertook two searches of the scientific literature. The first search sought pre-clinical studies which explained the reproductive endocrine effects of whole herbal extracts in oligo/amenorrhoea, hyperandrogenism and PCOS. Herbal medicines from the first search informed key words for the second search. The second search sought clinical studies, which corroborated laboratory findings. Subjects included women with PCOS, menstrual irregularities and hyperandrogenism.

Results: A total of 33 studies were included in this review. Eighteen pre-clinical studies reported mechanisms of effect and fifteen clinical studies corroborated pre-clinical findings, including eight randomised controlled trials, and 762 women with menstrual irregularities, hyperandrogenism and/or PCOS. Interventions included herbal extracts of *Vitex agnus-castus*, *Cimicifuga racemosa*, *Tribulus terrestris*, *Glycyrrhiza spp.*, *Paeonia lactiflora* and *Cinnamomum cassia*. Endocrine outcomes included reduced luteinising hormone (LH), prolactin, fasting insulin and testosterone. There was evidence for the regulation of ovulation, improved metabolic hormone profile and improved fertility outcomes in PCOS. There was evidence for an equivalent effect of two herbal medicines and the pharmaceutical agents bromocriptine (and *Vitex agnus-castus*) and clomiphene citrate (and *Cimicifuga racemosa*). There was less robust evidence for the complementary combination of spironolactone and *Glycyrrhiza spp.* for hyperandrogenism.

Conclusions: Preclinical and clinical studies provide evidence that six herbal medicines may have beneficial effects for women with oligo/amenorrhoea, hyperandrogenism and PCOS. However the quantity of pre-clinical data was limited, and the quality of clinical evidence was variable. Further pre-clinical studies are needed to explain the effects of herbal medicines not included in this review with current clinical evidence but an absence of pre-clinical data.

Background

Polycystic ovary syndrome (PCOS) is a complex, common reproductive and endocrine disorder affecting up to 17.8% of reproductive aged women [1]. Medical management places strong emphasis on a multidisciplinary approach as pharmaceutical treatments appear to be only moderately effective in treating individual symptoms [2,3]. Conventional pharmaceutical management is limited by the prevalence of contraindications in women with PCOS [3], non-effectiveness in some circumstances [4], side effects [5] and by preferences of women with PCOS for alternatives to pharmaceutical management [6]. This review examines the mechanisms of effect for a potential alternative treatment, herbal medicine, and reveals six herbal medicines with both pre-clinical and clinical data explaining the reproductive endocrinological effects in PCOS and associated oligo/amenorrhoea and hyperandrogenism.

Complementary medicine (CM) use by women has increased during the past ten years [7-11] with rates of use ranging between 26% and 91% [8,9]. One of the popular types of CM is herbal medicine [11,12]. Herbal medicines are known to contain pharmacologically active constituents with physiological effects on female endocrinology and have been positively associated with reduced incidences of breast cancer, osteoporosis and cardiovascular disease [13-18].

PCOS is a life-long condition and although the exact cause is yet to be identified, it is believed to have epigenetic origins, influenced by the uterine environment and behavioural factors [19]. Being overweight exacerbates all aspects of PCOS due to underlying metabolic disturbances [3]. Signs and symptoms are mediated by hormonal disorder including elevated androgens and fasting insulin, and abnormal relative ratio of the gonadotropins luteinising hormone (LH) and follicle stimulating hormone (FSH) [19]. Endocrine imbalances occur within the framework of disordered ovarian folliculogenesis, chronic anovulation, clinical signs of hyperandrogenism and metabolic syndrome [19].

Pharmaceutical treatment for menstrual irregularity includes the oral contraceptive pill (OCP) and ovulation induction with clomiphene citrate (clomiphene) [20,21] depending on fertility needs. Women with PCOS are however likely to exhibit contraindications for the OCP [3] and whilst induction of ovulation with clomiphene has demonstrated success, pregnancy rates remain inexplicably low [4]. Up to thirty 30% of women, particularly overweight women with PCOS, fail to respond to clomiphene therapy [4,22,23]. Management for hyperandrogenism includes anti-androgens and hypoglycaemic pharmaceuticals such as metformin [24]. Metformin has demonstrated effectiveness for improving insulin sensitivity and hyperandrogenism, however use of metformin is associated with the high incidence of adverse effects including nausea, vomiting and gastro-intestinal disturbances [5].

Herbal medicines are complex interventions with the potential for synergistic and antagonistic interactions between compounds [25]. Effects within the body may also exhibit complexity by simultaneous interactions with various body systems, both biochemically and by altering organ function [26]. The focus of this review was studies investigating whole herbal medicine extracts with direct effects on reproductive endocrinology for the treatment of women with irregular menstruation, hyperandrogenism and PCOS. The rationale for using this methodology was to identify herbal medicines with current scientific evidence explaining specific reproductive endocrinological effects in PCOS, oligo/amenorrhoea and hyperandrogenism, to develop understanding for the direct effects of herbal medicines on reproductive endocrinology and to highlight herbal medicines for which there was current scientific evidence supporting herbal medicine selection.

The purpose of this review is to inform clinical decisions in integrative settings and meet clinicians and consumers preferences for pragmatic herbal management within an holistic, individualised treatment frame [27,28].

We compared laboratory evidence including scientific studies using cell culture and animal models, with clinical data for proof-of-concept effects. A narrative synthesis of pre-clinical studies explaining reproductive endocrinological effects for herbal medicines with corroborative clinical evidence is presented.

Methods

We used the following definitions. PCOS according to the Rotterdam diagnostic criteria, specified by the presence of two out of three features: oligo/amenorrhoea, hyperandrogenism and polycystic ovaries on ultrasound [29,30]. Associated endocrine features for PCOS included elevated LH [31], which is strongly associated with infertility (p = 0.0003) [32] and miscarriage [33] and elevated fasting glucose which is prevalent in approximately 31% of women with PCOS including normal weight women [34].

Oligomenorrhoea was defined as menstrual cycle length that extended beyond 35 days (day one being the first day of menses). Amenorrhoea was defined as no menstrual period for three to six months or more [19]. This review was focussed on hypothalamic, pituitary and ovarian causes of menstrual irregularity with associated elevated gonadotropins including LH and prolactin and arrested folliculogenesis typically observed in polycystic ovaries. Hyperprolactinaemia is usually considered a unique cause for oligo/amenorrhoea; however in the present case it was included due to the potential co-existence for elevated prolactin, LH and PCOS, [32,35].

Hyperandrogenism was defined as clinical or biochemically excessive androgens. Clinical markers in females...
include cutaneous manifestations such as the presence of acne, hirsutism and/or male pattern alopecia. Biochemical indications include elevated plasma concentration of androgens.

We conducted two searches. The first was sensitive and aimed to capture all pre-clinical studies explaining the reproductive endocrine effects of whole herbal extracts in PCOS or associated oligo/amenorrhoea and hyperandrogenism. The second search was specific and sought only clinical studies investigating herbal medicines revealed during the first search (for which a mechanism of effect had been demonstrated). We additionally searched, on a case by case basis for pre-clinical evidence for herbal medicines identified during the second search, but not included in the results of the first search. Clinical studies were excluded based on the absence of evidence for a mechanism of effect for the whole herbal extract in reproductive endocrinology associated with PCOS, oligo/amenorrhoea and hyperandrogenism. We used this approach to improve transparency and to limit confirmation bias for herbal medicines favoured by the authors in clinical practice.

The first search revealed ten herbal medicines with a demonstrated mechanism of reproductive endocrinological effect for the whole herbal extract in PCOS, oligo/amenorrhoea and hyperandrogenism. These were Cimicifuga racemosa, Cinnamomum cassia, Curcuma longa, Glycyrrhiza spp., Matricaria chamomilla, Mentha piperita, Paeonia lactiflora, Silybum marianum, Tribulus terrestris and Vitex agnus-castus. Herbal medicines with a demonstrated mechanism of effect were entered as key terms in the second search.

We searched the following electronic databases: the Cochrane Library, MEDLINE ovidSP, CINAHL (1936 to present), SciVerse, EMBASE, PubMed, from the date of database inception to June 2014. In addition, we manually searched bibliographies of review articles.

Key terms for the first search included: title or abstract CONTAINS ‘herbal medicine’ OR ‘herbal extract’ OR ‘phytotherapy’ OR ‘botanical’ AND title or abstract CONTAINS ‘androgen’ OR ‘oestrogen’ OR ‘follicle stimulating hormone’ OR ‘luteinising hormone’ OR ‘prolactin’ OR ‘insulin’ OR ‘glucose’ OR ‘polycystic ovar’’. Search terms for the second search included the following key words in the title or abstract, CONTAINS; ‘menstrual irregularity’ OR ‘oligomenorrhoea’ OR ‘amenorrhoea’ OR ‘hyperandrogenism’ OR ‘hirsutism’ OR ‘acne’, OR ‘polycystic ovary syndrome’ OR ‘PCOS’ OR ‘polycystic ovar’ OR ‘oligo-ovulation’ OR ‘anovulation’ OR ‘fertility’ OR ‘infertility’ OR ‘pregnancy’ AND ten herbal medicines identified from the laboratory search; ‘Cimicifuga racemosa’ OR ‘Cinnamomum cassia’ OR ‘Curcuma longa’ OR ‘Glycyrrhiza’ OR ‘Matricaria chamomilla’ OR ‘Mentha piperita’ OR ‘Paeonia lactiflora’ OR ‘Silybum marianum’ OR ‘Tribulus terrestris’ OR ‘Vitex agnus-castus’. Truncation was used to capture plural key words and synonyms, and acronyms were used for some hormones (FSH and LH).

Our laboratory search included investigations into the effects of herbal medicine using computer models, cell cultures, animals with PCOS induced with oestradiol valerate and androgens and sterilised and ovariectomised rats. We excluded laboratory studies which commenced using isolated chemicals not directly extracted from crude herbal medicines and studies examining androgen effects in male animals.

Our second search for clinical trials was performed without language restriction and included randomised controlled trials, non-randomised, open label and single arm clinical trials. We included clinical studies investigating commercially available herbal extracts and investigations that compared the effectiveness of herbal medicine with pharmaceuticals. We excluded clinical studies investigating herbal medicines with unrelated outcomes (including pre-menstrual syndrome, endometriosis and mastalgia) and clinical studies examining the effectiveness of complex herbal formulas for PCOS and associated oligo/amenorrhoea and hyperandrogenism, without demonstration of a mechanism of effect for the whole complex formula. We compared data from laboratory and animal studies with the outcomes of clinical trials. Clinical studies were assessed for risks of bias at study and outcome levels with risks summarised, tabulated (Tables 1 and 2) and presented in contextual narrative.

Results
Laboratory studies
Our search identified 33 laboratory (pre-clinical) studies (Figure 1). Eighteen studies met the inclusion criteria, nine reported on receptor binding assays or ovarian or pituitary (brain) cell cultures, [36-44] and nine used an animal experimental model with hormone assays and/or post-mortem examination of ovarian, uterine and brain histology, [45-53] (Table 1). We excluded 15 studies for the following reasons; investigation of effects in male animals (n = 4) and investigations which commenced with constituents that were isolated from herbal medicines (n = 5). Six studies were excluded due to no clinical evidence found (n = 6).

Clinical studies
Following the electronic and manual searches of bibliographies, forty six clinical studies were identified for inclusion/exclusion assessment (Figure 1). A pre-requisite for the inclusion of clinical studies was identified laboratory evidence explaining the mechanism of effect in reproductive endocrinology. Fifteen met the inclusion criteria [54-68]. Eight were randomised controlled trials (RCTs) including 762 women [61-68] (Table 2). Thirty one studies were excluded for the following reasons; investigation of
| Herbal medicine | Evidence | Clinical RCTs (detailed in Table 2) | Physiological effects in menstrual irregularity (oligo/amenorrhoea), hyperandrogenism and/or PCOS. |
|----------------|----------|------------------------------------|-----------------------------------------------|
| **Herbal extract** | **Pre-clinical in vitro and in vivo** | |  |
| **Herbal medicine** | **Botanic name** | |  |
| **Vitex agnus-castus** | Eight studies investigated gonadotropin hormone concentration effects of Vitex agnus-castus. | Three RCTs investigate clinical effectiveness for Vitex agnus-castus for oligo/amenorrhoea and PCOS [61,62,64]. | 1. Lowers prolactin due to dopaminergic effects [38-41,63]. |
| Ethanol extracts | 1. Investigation for equivalence of dopaminergic effects for Vitex agnus-castus and the pharmaceutical Lisuride using rat pituitary cell cultures (basal and stimulated cells) [41] | 2. No change for serum prolactin [64] | |
| Strontan®, Mastodynon®, Phyto-hypophyson®, Agnacaston® | 2. Brain (calf, guinea pig and rats) receptor tissue cultures including DA2, histamine and 5HT transporters. Radio ligand and super-fusion experiments [40] | 3. FSH no change [39] | |
| | 3. Three investigations found affinity for Vitex agnus-castus and β oestrogen receptors [38,43,69] | 4. LH no change [39] | |
| | 4. Using recombinant human dopamine (DA2) receptor proteins [38] | 5. LH lowered [49] | |
| | 5. The affinity of Vitex agnus-castus extract (with and without fatty acids) for human μ opioid receptor cells cloned and transfected into hamster ovary cells [70] | 6. Binds to β oestrogen receptors [38,43,69] | |
| | 6. The endocrine effects for Vitex agnus-castus were investigated in normal and ovariectomised rats [49] | 7. Increased serum oestradiol [49,64] | |
| | 7. Corpus striatum membrane including D2 receptors to assess the inhibitory properties of Vitex agnus-castus on prolactin, FSH and LH [39] | 8. Increased serum progesterone [49,62] | |
| | 8. Increased serum progesterone [49,62] | 9. Improved pregnancy rates [61,62] | |
| **Cimicifuga racemosa** | Four laboratory studies investigated pituitary oestrogen receptor binding and gonadotropin concentrations following exposure to Cimicifuga racemosa. | Three RCTs demonstrate positive fertility effects for Cimicifuga racemosa in women with PCOS [65,67,68] | 1. Binds with α oestrogen receptors [44] in the pituitary and reduces LH secretion [45,52,68]. |
| Ethanol extract | 1. One study investigated a constituent flavonoid of Cimicifuga racemosa, discovered during the course of the study for reduction for LH in ovariectomised rats [37] | 2. Increases luteal progesterone concentration [65,67,68] | |
| Klimadynon® | 2. Oestrogen receptor binding affinity for Cimicifuga racemosa was studied using pituitary cell cultures from ovariectomised rats. This study followed a clinical study demonstrating significantly lowered LH in post-menopausal women following administration of Cimicifuga racemosa (2 mg for two months) against placebo control (n=110) [45] | 3. Improves endometrial thickness for infertile women with PCOS [65,67,68]. | |
| | 3. Binding affinity for oestrogen receptors (ERa) for Cimicifuga racemosa examined using MCF7 cell cultures [44] | 4. Lowers LH in women with PCOS [65,67,68] | |
| | 4. Chronic and acute dosage effects of Cimicifuga racemosa and oestradiol on oestrogen receptors, gene expression, uterine and bone tissue of ovariectomised rats [52] | 5. Improves FSH:LH ratio for women with PCOS [67] | |
| | | 6. Limits anti-oestrogen effects when used in combination with Clomiphene citrate for women with PCOS [65,68] | |
Table 1 Summary of evidence for the reproductive endocrinological effects of six herbal medicines in oligo/amenorrhoea, hyperandrogenism and PCOS (Continued)

| Herbal medicine | Evidence | Data from clinical studies (non RCTs) |
|-----------------|----------|-------------------------------------|
| **Herbal medicine** | **Botanic name** | **Physiological effects in oligo/amenorrhoea, hyperandrogenism and/or PCOS** |
| **Cinnamon cassia** | Aqueous extract (animal study) | One animal study compared the effectiveness of *Cinnamomum cassia* with metformin against controls in rats with PCOS. Hormone concentration was measured at 15 and 30 days [48]. |
| **Tribulus terrestris** | Ethanol extracts | Three animal studies investigated the effects of *Tribulus terrestris*, two for polycystic ovaries and one on oestrogen sensitive tissues in rats. |
| | | 1. One study examined the oestrogenic effects of *Tribulus terrestris* on uterine and vaginal tissue of ovariectomised rats [51]. |
| | | 2. Two studies investigated the ovulation rates, number of corpus luteum and follicle characteristics in rats with polycystic ovaries following exposure to various doses of *Tribulus terrestris* [46,47]. |
| **Glycyrrhiza glabra** (European liquorice) | Ethanol extract | Two preclinical studies investigated the effects of *Glycyrrhiza glabra* spp. for steroid hormone concentration and in polycystic ovaries. |
| | | 1. Steroid hormone concentration in sterilised and oophrectomised rats following exposure to *Glycyrrhiza glabra* spp. (kanzo) [53]. |
| | | 2. Morphological features of polycystic ovaries of rats following exposure to two Chinese herbal compounds with only *Glycyrrhiza glabra* spp. as a common ingredient [50]. |
| **Glycyrrhiza uralensis** (Chinese liquorice) | Aqueous extract used in two pre-clinical studies | Two clinical trials |
| | | 1. Single arm clinical trial investigating serum androgen concentration in healthy women aged 22–26, (n = 9) following administration of *Glycyrrhiza uralensis* 7grams per day [53]. |
| | | 2. Single arm clinical trial including women with PCOS (n = 32) taking Spirinolactone [54]. |

1. Equivalence for metformin for reduced testosterone in PCOS [48].
2. Equivalence for metformin for reduced LH in PCOS [48].
3. Equivalence for metformin for reduced LH in PCOS [48].
4. Equivalence for metformin for reduced insulin resistance [48].
5. Improved metabolic profile for overweight women with PCOS [66].
Table 1 Summary of evidence for the reproductive endocrinological effects of six herbal medicines in oligo/amenorrhoea, hyperandrogenism and PCOS (Continued)

| Herbal Medicine Combination | Effects on Endocrine Parameters |
|-----------------------------|--------------------------------|
| **Paeonia lactiflora** in combination with *Glycyrrhiza spp.* Aqueous extract Shakuyaku-kanzo-to (TJ-68) | One laboratory study examined the effects for the combination *Paeonia lactiflora* and *Glycyrrhiza uralensis* on testosterone, oestradiol, FSH and LH in sterilised female rats [53]. | **1.** Reduced total and free testosterone [53,58,59].  
**2.** Increased SHBG [59].  
**3.** Reduced LH [53].  
**4.** Reduced LH:FSH ratio [59].  
**5.** Oestradiol slight increase (not significant) [53]. |
| **Paeonia lactiflora** in combination with *Cinnamomum cassia* Aqueous extract Unkei-to | *Paeonia lactiflora* and *Cinnamomum cassia* combination was investigated for steroid hormonal effects on cultured human granulosas cells (obtained from women undergoing IVF). Cells were incubated with different doses for 48 hour [42]. | **1.** Increased granulosa production of oestradiol [42].  
**2.** Increased granulosa production of progesterone [42].  
**3.** Reduced LH in oligo/amenorrhoea [57].  
**4.** Improved ovulation rates in oligo/amenorrhoea [57]. |
Table 2 Summary of randomised controlled trials for five herbal medicines in oligo/amenorrhoea, hyperandrogenism and PCOS

| Author and year of publication | Study design and duration | Subjects | Intervention | Outcome measures | Results and level of significance | Comments |
|-------------------------------|---------------------------|----------|--------------|-----------------|---------------------------------|----------|
| Kilicdag [63]                 | Randomised comparative effectiveness trial. Treatment for 3 months. | Eighty women, 40 with hyperprolactin-aemia, 40 with cyclical mastalgia. | Herbal extract Vitis agnus-castus 40 mg in the commercial preparation Agnucaston® by Biornica, Germany. 1 tablet per day. | Comparison of difference between Vitis agnus-castus and Bromocriptine for serum prolactin concentration on days 5–8 of the menstrual cycle. | Mean prolactin concentration before and after in the Vaguss-castus arm: 946 mIU/L (±173.5) to 529 mIU/L (±279.7), p < 0.0001. In the Bromocriptine arm: 885 mIU/L (±177.5) to 472 mIU/L (±265.0), p < 0.0001. | All participants completed the trial. Adverse reactions: zero reported in V. agnus-castus group; 12.5% of participants reported adverse reactions in the Bromocriptine group (nausea and vomiting). Small sample sizes with 2 subgroups. Insufficiently powered to correctly identify the effects; 37 participants were required (±2%, 95% confidence). |
| Gerhard I, Luft B, et al. [61] | Randomised, double blind, placebo controlled trial. Three months. Follow up at 2 years | Ninety-six women with fertility disorders and confirmed infertility (2 years). | Vitis agnus-castus 32.4 mg/d in the commercial preparation Mastodynon® liquid extract produced by Biornica, Germany. 30 drops per day over 3 months. | Spontaneous menstruation, luteal phase length, serum hormone concentrations and pregnancy rates. | Hormonal data from 32 cases. In the third treatment month 66 complete data sets were available. Reasons were as follows: 4 due to drug reactions and 15 due to pregnancy. Four withdrew for unknown reasons. Non-significant improvement in clinical parameters in 57.6% of women in treatment group versus 36.0% in placebo group, P = 0.069. In a subgroup of women with luteal insufficiency (n = 21) there were significant improvements in clinical parameters in the treatment group compared to placebo (p = 0.023). 15 women conceived in the treatment group compared to 8 in placebo group in the first 3 months (while women were treated). All pregnant women were withdrawn from the study. 4 women had miscarriages, all in the active arm. After 2 years there were 21 more pregnancies with 2 miscarriages – evenly spread over active and placebo groups. | Numbers too small for statistical significance in clinical outcomes. Preparation ‘Mastodynon’ contains V. agnus-castus plus other herbal extracts which may have confounded outcome measures. Inconsistencies in data assessment include the recommendation for treatment with Mastodynon over 3–6 months yet it was tested for 3 months. Women with infertility were included in this study however data from women who conceived were excluded. This may have led to an underestimation of treatment effect (type 1 error). |
| Bergmann I, Peter A, et al. [62] | Randomised, placebo controlled double blind study. Three months or 3 menstrual cycles. | Women with fertility disorders, (n = 67). Two sub-groups. | Herbal extract Phyto-Hypophyson® by Steri-Pharma GmbH Hemsching, Germany; contains Vitis agnus-castus plus Ochledonium majus and Silybum marianum (St Mary’s thistle) in homeopathic form. Additional herbal extracts have reported activity in hepatic function. There are no reports for direct reproductive effects. | History for participants with amenorrhoea: at least one spontaneous menses. For progestrone < 1 ng/ml: an increase to > 5 ng/ml at the end of 3rd cycle. | For oligomenorrhoea: Shortened menstrual cycle of at least 4 days. Earlier ovulation of at least 3 days. For anovulatory oligomenorrhoea: Mid luteal progesterone increase (> 50%) 5–10 days before menstruation. Secondary clinical outcomes, pregnancy rates and take home baby rates. | Oligomenorrhoeic subgroup - clinical outcomes were significantly improved in the treatment arm at 80% compared to 45% in placebo arm P = 0.001. When the amenorrhoeic group were included in analysis, differences were not significant p = 0.13. Mid luteal progesterone concentration in oligomenorrhoeic sub-group was significantly higher than the placebo group p = 0.0049. At 6 months following conclusion of treatment, the take home baby rate with treatment was 18.7% compared to 6.4% in placebo group. Not statistically significant. | Diagnosis for anovulatory oligomenorrhoea is not well described. Non-statistically significant take home baby rates were complicated by insufficient sample size. 366 patients are required to have a 95% chance, as significant at the 5% level, an increase in take home baby rates from 6% in the placebo group to 18% in the experimental group. The authors conclude that this preparation may be useful if given 3–6 months, yet they only tested for 3 months. |
Table 2 Summary of randomised controlled trials for five herbal medicines in oligo/amenorrhoea, hyperandrogenism and PCOS (Continued)

| Study Authors | Trial Design | Sample Description | Study Intervention | Study Outcomes |
|---------------|--------------|-------------------|-------------------|---------------|
| Milewicz A, Gejdel E, et al. [64] | Randomised placebo controlled, double blind, trial. Three months. | 52 women with latent hyperprolactinaemia and luteal phase defects. Participants stratified for cycle length, height (cm) and weight (kg) and randomised. Baseline differences between arms were not significant. p = 0.63, p = 0.48 and p = 0.37 respectively. 37 complete case reports: Treatment arm n = 17, placebo n = 20. | Vitis agnus-castus extract 20 mg in the commercial preparation of Strotan® Hersteller: Pharma Stroschein GmbH, Hamburg, Germany. 1 capsule per day or placebo. | Serum prolactin concentration at 15 and 30 minutes following intra venous TRH (200mcg) stimulation. Luteal phase length, number of days. Measurements on menstrual cycle days 5 to 8 and 20 for FSH, LH, oestradiol, progesterone, DHEAS, thyroid stimulating hormone (TSH), T3, T4, testosterone. No significant changes in prolactin before and after in either group. In this study 52 women were eligible to participate, statistical analyses were performed on data from 37 women. There is missing data due to the presence of luteinised, unruptured follicles (9 women). These data were not included in analyses. Six women did not present for further investigation. No description of the distribution of drop-outs or missing data. This suggests the potential imbalance between intervention and control and a possible over-exaggeration for treatment effect. |}

| Shahin et al. [65] | Randomised controlled trial using an active control arm for comparative assessment. One menstrual cycle. | 147 women aged less than 35 years with un-explained infertility and recurrent clomiphene resistance for ovulation induction. Anovulatory participants were excluded (n = 28). Anovulation was diagnosed by serum oestradiol < 200 ng/ml and absence of a dominant ovarian follicle on day 9 of the menstrual cycle. Complete data sets available for 119 women. All women received Clomiphene citrate (clomiphene) 150 mg on menstrual cycle days 3–7. A randomised group also took Cimicifuga racemosa 20 mg per day between days 1–12. Cimicifuga racemosa described as ‘phytoestrogens’ was provided in the commercial preparation Klimadynon®, manufactured by Norica in Germany. A trigger injection (human chorionic gonadotropin, 10 000 IU) and timed intercourse was recommended when a dominant follicle > 17 mm was observed. | Clomiphene citrate (clomiphene) 150 mg on menstrual cycle days 3–7. A randomised group also took Cimicifuga racemosa 20 mg per day between days 1–12. Cimicifuga racemosa described as ‘phytoestrogens’ was provided in the commercial preparation Klimadynon®, manufactured by Norica in Germany. A trigger injection (human chorionic gonadotropin, 10 000 IU) and timed intercourse was recommended when a dominant follicle > 17 mm was observed. | Pregnancy rate measured as increasing serum human chorionic gonadotropin (HCG) over two days. Clinical pregnancy defined as detection of gestational sac with embryonic heart-beat. Endometrial thickness measured by ultrasound concurrent with follicle maturation monitoring. Number of days to ovulation (trigger injection) Serum concentration for FSH, oestradiol and LH. Luteal progesterone measured on days 21–23 of the menstrual cycle. Miscarriage and multiple pregnancy rates. | Number of days to ovulation (trigger injection) Serum concentration for FSH, oestradiol and LH. Luteal progesterone measured on days 21–23 of the menstrual cycle. Miscarriage and multiple pregnancy rates. | Pregnancy rate in clomiphene alone group was 20.3% and 43.3% in the clomiphene plus Cimicifuga racemosa group (P < 0.01). Clinical pregnancy rate in the combination group was 36.7% versus 13.6% in the clomiphene alone group (P < 0.01). Endometrial thickness in combination group was 89 (±14) versus 75 (±13) (P < 0.001). Days to ovulation in clomiphene alone group was 13.0 ± 1.1 and in the clomiphene plus Cimicifuga racemosa group 14.2 ± 1.3 (n.s.). Luteal progesterone peak (ng/ml) in combination group was 13.3 (±3.1) versus 9.3 (±2.0) in clomiphene alone group (P < 0.01). All other hormone measures were not significantly different. |}

| Arentz et al. BMC Complementary and Alternative Medicine 2014, 14:511 | Randomised placebo controlled, double blind, trial. Three months. | 52 women with latent hyperprolactinaemia and luteal phase defects. Participants stratified for cycle length, height (cm) and weight (kg) and randomised. Baseline differences between arms were not significant. p = 0.63, p = 0.48 and p = 0.37 respectively. 37 complete case reports: Treatment arm n = 17, placebo n = 20. | Vitis agnus-castus extract 20 mg in the commercial preparation of Strotan® Hersteller: Pharma Stroschein GmbH, Hamburg, Germany. 1 capsule per day or placebo. | Serum prolactin concentration at 15 and 30 minutes following intra venous TRH (200mcg) stimulation. Luteal phase length, number of days. Measurements on menstrual cycle days 5 to 8 and 20 for FSH, LH, oestradiol, progesterone, DHEAS, thyroid stimulating hormone (TSH), T3, T4, testosterone. No significant changes in prolactin before and after in either group. In this study 52 women were eligible to participate, statistical analyses were performed on data from 37 women. There is missing data due to the presence of luteinised, unruptured follicles (9 women). These data were not included in analyses. Six women did not present for further investigation. No description of the distribution of drop-outs or missing data. This suggests the potential imbalance between intervention and control and a possible over-exaggeration for treatment effect. | Pregnancy rate measured as increasing serum human chorionic gonadotropin (HCG) over two days. Clinical pregnancy defined as detection of gestational sac with embryonic heart-beat. Endometrial thickness measured by ultrasound concurrent with follicle maturation monitoring. Number of days to ovulation (trigger injection) Serum concentration for FSH, oestradiol and LH. Luteal progesterone measured on days 21–23 of the menstrual cycle. Miscarriage and multiple pregnancy rates. | Pregnancy rate in clomiphene alone group was 20.3% and 43.3% in the clomiphene plus Cimicifuga racemosa group (P < 0.01). Clinical pregnancy rate in the combination group was 36.7% versus 13.6% in the clomiphene alone group (P < 0.01). Endometrial thickness in combination group was 89 (±14) versus 75 (±13) (P < 0.001). Days to ovulation in clomiphene alone group was 13.0 ± 1.1 and in the clomiphene plus Cimicifuga racemosa group 14.2 ± 1.3 (n.s.). Luteal progesterone peak (ng/ml) in combination group was 13.3 (±3.1) versus 9.3 (±2.0) in clomiphene alone group (P < 0.01). All other hormone measures were not significantly different. | Unaccounted confounding factors include medications, fertility status, duration of latent hyperprolactinaemia. No detailed current baseline criteria for other causes of infertility. Confounding factors include current male fertility status. This may have caused an imbalance between the two groups. There is no description of the distribution of excluded (anovulatory) participants between groups. |
Table 2 Summary of randomised controlled trials for five herbal medicines in oligo/amenorrhoea, hyperandrogenism and PCOS (Continued)

| Trial | Design | Participants | Intervention | Outcome Measures | Comments |
|-------|--------|--------------|--------------|------------------|----------|
| Kamel [67] | Randomised controlled trial with an active control group. Comparative effectiveness trial for ovulation induction in women with PCOS. Three menstrual cycles. | Women aged 21–27 with primary or secondary infertility. Diagnosis of PCOS by ultrasound and clinical history (n = 100). Gynaecology outpatient clinic. Two groups. Group one (n = 50) received Clomiphene citrate 100 mg days 2–7 of menstrual cycle; group two (n = 50) received 20 mg Cimicifuga racemosa for days 2–12 of the menstrual cycle. | Cimicifuga racemosa extract Klimadynon® by Bionorica, Neumarkt i.d. OBF Germany. 20 mg twice daily days 2–12 of menstrual cycle Clomiphene citrate (clomiphene) 100 mg daily for days 2–7 of menstrual cycle. Trigger injection (human chorionic gonadotropin Pregnyl) and timed intercourse recommended when dominant follicle (>18 mm) was observed on ultrasound. | Serum measurements during follicular phase for FSH, LH and FSH:LH ratio. Mid luteal progesterone. Ultrasound observation of endometrial thickness. Pregnancy rates including twin pregnancies. Adverse events including hyperstimulation. | Positive outcomes for Cimicifuga racemosa compared to clomiphene for reduced day 2–5; LH (p = 0.007) and improved FSH to LH ratio (p = 0.06), mid luteal progesterone (p = 0.0001), endometrial thickness (p = 0.0004). Pregnancy rates were higher in the Cimicifuga racemosa group (7/50 compared to 4/50) but not statistically significant (p = 0.1). Adverse events (4 women) and twin pregnancy's (2 women) were not significantly different between groups. |
| Shahin [68] | Non-blinded randomised controlled trial. | Women with PCOS and infertility, n = 194. | All participants received pharmaceutical ovulation induction (Clomiphene citrate 150 mg on days 3–7 of cycle); trigger injection (HCG 10000 IU Pregnyl), timed intercourse and progesterone support (oral micronized progesterone). A randomly selected group additional took Cimicifuga racemosa 120 mg per day (Klimadynon®). | Primary outcomes pregnancy rates. Secondary outcomes: 1. Number of days to ovulation (trigger injection). Follicular maturation monitored by ultrasound. 2. Endometrial thickness monitored by ultrasound. 3. Serum hormones during follicular phase oestradiol, LH and FSH. Luteal progesterone measured day 21–23 of the cycle. 4. Pregnancy outcomes for early miscarriage. | Pregnancy rates were 33 out of 192 cycles (17.2%) for the clomiphene alone group and 71 out of 204 cycles (34.8%) for the clomiphene plus Cimicifuga racemosa group. |
| Arentz et al. BMC Complementary and Alternative Medicine 2014, 14:511 | Three menstrual cycles each separated by two months of no treatment. | Two groups matched for demographics, age, BMI, primary and secondary infertility and duration of infertility (months). Treatment arm n = 96, control n = 98. Randomisation for 206 women 12 were excluded due to failure to respond (treatment group n = 7, control n = 5). | | Pregnancy rates were 33 out of 192 cycles (17.2%) for the clomiphene alone group and 71 out of 204 cycles (34.8%) for the clomiphene plus Cimicifuga racemosa group. Number of days to trigger injection was 15 (±1.7) for the clomiphene alone group and 12.0 (±1.9) in the clomiphene plus Cimicifuga racemosa group (p = 0.01). Endometrial thickness in the clomiphene alone group was 8.5 mm (±1.9) compared to 12.9 (±2.3) in the clomiphene plus Cimicifuga racemosa group (p < 0.001). Serum LH was 8.0 (±0.9) in the clomiphene group and 5.7 (±0.9) in the clomiphene plus Cimicifuga racemosa group (p < 0.001) and oestradiol was 228.3 (±30.2) in the clomiphene alone group and 299.5 (±38.9) in the clomiphene plus Cimicifuga racemosa group (p = 0.01). | | Non-blinding compromised the internal validity of the findings in this study. Confounding variables include variations in participants and clinicians attitudes and may have led to differences which were unaccounted for between the two groups. However the outcomes are objective with a statistically powered sample size. Measures for miscarriages are based on per cycle are not valid. Miscarriages per pregnancy are of greater relevance. The miscarriage rate per pregnancy for the clomiphene alone group was 5 out of 33 (15.2%) and 6 out of 71 (8.5%) in the clomiphene plus Cimicifuga racemosa group. |
| Study            | Design                  | Participants                                                                 | Interventions                                                                 | Primary outcomes                                                                 | Secondary outcomes                                                                 | Adverse events                                                                 | Comments                                                                 |
|------------------|-------------------------|------------------------------------------------------------------------------|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------|------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Wang et al. 2008 | Double blinded, placebo | 15 overweight women with oligo/amenorrhea and polycystic ovaries on ultrasound. Mean body mass index 28.8 ± 1.3 kg/m². Mean age 31.1 ± 2.0 years. | Cinnamomum cassia extract 333 mg (Integrity Nutraceuticals International Sarasota, Florida) or placebo. One tablet three times per day. | Insulin resistance and sensitivity. Improved insulin sensitivity (QUICKI) in the treatment group. 0.35 to 0.38, (7.7%) p < 0.03. Insulin resistance (HOMO-IR) significantly reduced in treatment group 2.57 to 1.43 (44.5%) p < 0.03. Controls no change in insulin sensitivity or insulin resistance. No change in either group for BMI, testosterone and oestradiol. Differences between Cinnamomum cassia group and normal weight and ovulatory controls were not significant. (P < 0.17). No reported adverse reactions. | No change in either group for BMI, testosterone and oestradiol. Differences between Cinnamomum cassia group and normal weight and ovulatory controls were not significant. (P < 0.17). No reported adverse reactions. | Small pilot study, the authors report that larger studies are required to confirm findings. Small sample size may explain non-significant comparison with normal weight and ovulating women. Reproductive outcomes were unchanged in this study however the duration of the study was insufficient to demonstrate reproductive changes. |
isolated herbal chemicals (n = 3); inclusion of male subjects (n = 4); no pre-clinical evidence (n = 11) and conditions different to those specified (n = 13).

**Excluded studies**
Details of excluded studies investigating herbal medicines with clinical evidence but no preclinical evidence were provided in Table 3. Herbal medicines with preclinical evidence but no clinical evidence were provided in Table 4, and investigations into isolated chemicals derived from herbal medicine were presented in Table 5.

Seven RCTs examined commercially produced herbal medicine extracts. These were *Vitex agnus-castus* in the form of Strontan®[64], Mastodynon®[61], Phyto Hypophyson®[62] and Agnacaston®[63] and *Cimicifuga racemosa* in the form of Klimadynon® [65,67,68] (Table 2).

**Herbal medicines with effects in oligo/amenorrhoea, hyperandrogenism and PCOS**
The results of preclinical studies and clinical studies have been summarised together for each of the six herbal medicines.

**Vitex agnus-castus**
Pre-clinical and clinical evidence was found for *Vitex agnus-castus* for lowered prolactin, improved menstrual regularity and treatment of infertility. *Vitex agnus-castus* contains a variety of compounds which bind to dopamine type 2 (DA-2) receptors in the brain; reduce cyclic adenosine mono phosphate (cAMP) and lowered prolactin secretion (Table 1). This was demonstrated in studies using recombinant DA-2 receptor proteins, and basal and stimulated rat pituitary cell cultures [38-41]. Prolactin lowering effects were found in normal and ovariectomised rats [49]. Additional agonistic opiate effects were

Table 3 Herbal medicines with clinical evidence not included in this review

| Herbal medicine             | Clinical evidence (or potential) for PCOS and associated oligo/amenorrhoea or hyperandrogenism | Reason for non-inclusion – insufficient pre-clinical evidence for mechanism of effects for whole herbal extract |
|----------------------------|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Camellia sinensis          | Hormone concentration in obese women with PCOS [71].                                            | Isolated constituent (epigallocatechin gallate 1) examined in PCOS, oligo/amenorrhoea and hyperandrogenism. |
| Mentha spicata             | Lowered testosterone in women with PCOS [73,74].                                               | No evidence for mechanism of effect found for PCOS, oligo/amenorrhoea or hyperandrogenism.                 |
| Grifola frondosa (maitake mushroom) | Metabolic hormone management for type two diabetes [75].                                  | No evidence for mechanism of effect in PCOS, oligo/amenorrhoea or hyperandrogenism found.                  |
| Linum usitatissimum         | Ovulation rates in PCOS [76].                                                                 | No evidence for mechanism of effect in PCOS, oligo/amenorrhoea or PCOS revealed.                          |
| Pygeum africanum           | Anti-androgen effects in prostatic hypertrophy [81].                                             | No evidence for mechanism of effect found in PCOS, oligo/amenorrhoea or hyperandrogenism.                  |
| Silybum marianum           | Menstrual regulation [77,78] and hormonal concentration [78-80] in post-menopausal women.        | No mechanism of effect in PCOS, oligo/amenorrhoea or hyperandrogenism found.                             |
| Serenoa repens             | Anti-androgen effects in chronic pelvic pain and prostatitis [82-84].                           | No mechanism of effect in PCOS, oligo/amenorrhoea or hyperandrogenism (in female cell cultures or animals).|
| Stachys lavandulifolia      | Fatty liver disease in type two diabetes [85].                                                   | No mechanism of effect in PCOS, oligo/amenorrhoea or hyperandrogenism.                                   |
| Urtica dioica              | Anti-androgen effects in women [87].                                                             | Anti-androgen effects through interaction with SHBG in prostate cells [88-90].                           |

Reason for exclusion:

- Isolated constituent (epigallocatechin gallate 1) examined in PCOS, oligo/amenorrhoea and hyperandrogenism.
- No evidence for mechanism of effect found for PCOS, oligo/amenorrhoea or hyperandrogenism.
- No evidence for mechanism of effect found in PCOS, oligo/amenorrhoea or hyperandrogenism.
- No evidence for mechanism of effect found in PCOS, oligo/amenorrhoea or PCOS revealed.
- No evidence for mechanism of effect in PCOS, oligo/amenorrhoea or hyperandrogenism (in female cell cultures or animals).
- No mechanism of effect found in PCOS, oligo/amenorrhoea or hyperandrogenism (in female cell cultures or animals).
- No mechanism of effect in PCOS, oligo/amenorrhoea or hyperandrogenism.
- Anti-androgen effects through interaction with SHBG in prostate cells [88-90].
- Anti-inflammatory and anti-nociceptive effects [91].
- No evidence for effects of Urtica dioica in female cell cultures or animals.

Other excluded studies investigated the herbal medicines included in this review examining conditions other than PCOS, oligo/amenorrhoea and hyperandrogenism. These included investigations into effectiveness for Vitex agnus-castus for pre-menstrual syndrome [92-97] and mastalgia [98,99], Cimicifuga racemosa for menopausal symptoms [100] and Glycyrrhiza spp with Paeonia lactiflora libido in males [101].

observed in studies using human opiate receptors cell cultures [70].

Clinical equivalence for prolactin lowering effects of Vitex agnus-castus (Agnucaston® 40 mg per day) and the pharmaceutical Bromocriptine (Parlodel® 5 mg per day) was found in one study including 40 women with hyperprolactinaemia [63]. Mean concentrations for prolactin were effective treatment for women with hyperprolactinaemia (normal reference range 25-628 mIU/l). The mean difference in prolactin reduction of the two groups was not significant (p = 0.96) (Table 2).

Positive effects for Vitex agnus-castus in oligo/amenorrhoea and infertility was demonstrated in three placebo controlled RCTs [61,62,64]. In a study including prolactin concentration in the Bromocriptine group was significantly reduced from 885 mIU/l (±178) to 473 mIU/l (±266) (p < 0.001) demonstrating that both treatments were effective treatment for women with hyperprolactinaemia (normal reference range 25-628 mIU/l). The mean difference in prolactin reduction of the two groups was not significant (p = 0.96) (Table 2). Studies investigating chemical compounds derived from the herbal medicines, included in this review but investigating different outcomes were found for Vitex agnus-castus [70] and Cimicifuga racemosa [106].

Table 4 Herbal medicines with pre-clinical evidence not included in this review

| Herbal medicine              | Pre-clinical evidence for (potential) effects in reproductive endocrinology in PCOS and associated oligo/amenorrhoea and hyperandrogenism | Reason for exclusion |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Curcuma longa (turmeric)     | Anti-androgen effects [102].                                                                                                      | No clinical evidence examining effectiveness in women was found. |
| Matricaria chamomilla (Chamomile) | Reduced luteinising hormone and improved ovarian morphology in animals with PCOS [103].                                                 | No clinical data found. |
| Mentha piperita (peppermint) | Anti-androgen effects in animals [104].                                                                                          | No clinical data for women. |
| Silybum marianum (St Marys thistle) | Anti-proliferative antioxidant and biochemical effects in the liver [105].                                                           | No clinical evidence including women was found. |

Studies investigating chemical compounds derived from the herbal medicines, included in this review but investigating different outcomes were found for Vitex agnus-castus [70] and Cimicifuga racemosa [106].
Table 5: Chemicals derived from herbal medicines not included in this review

| Isolated chemicals                             | Evidence for effects                                                                 |
|------------------------------------------------|----------------------------------------------------------------------------------------|
| Phytoestrogens                                 | Hormonal effects in ovarian granulosa cells [107].                                     |
| Berberine                                      | Comparison with metformin in PCOS [16]; ovarian theca cell hormone production [108].  |
| Catechin derived from Camellia sinensis        | Effects of epigallocatechin gallate 1 on cellular metabolic endocrinology [72].        |
| Saponins derived from Tribulus terrestris      | Effects on reproductive endocrinology [109].                                           |
| Paeoniflorin, glycyrrhizin and glycyrrhetic acid| Ovarian androgen production [110].                                                    |
| Isoflavones isolated from Vitex agnus-castus    | Selective oestrogen receptor activity (competitive inhibition via beta oestrogen receptors) [36]. |

women with menstrual irregularity and infertility (n = 96), menstrual cyclicity was significantly improved for women treated with Vitex agnus-castus (Mastodynon® 30 drops per day for three months) compared to placebo (p = 0.023) [61] (Table 2). Another study, including women with sub fertility (n = 67), showed improved menstrual cyclicity for a sub-group of women with oligomenorrhoea following treatment with Vitex agnus-castus (Phyto-Hypophyson® 7.5 ml per day) compared to placebo, (p = 0.023) [62] (Table 2). A third study including women with hyperprolactinaemia (n = 37) demonstrated improved menstrual cyclicity by an increased average number of luteal days from 3.4 days (±5.0) to 10.5 days (±4.3) (p < 0.005) following treatment with Vitex agnus-castus (Strotan® 20 mg per day) for three months. The placebo group reported average number of days in the luteal phase was 3.4 (±5.1) at baseline and 5.5 (±5.2) at three months, which was not significant (p = 0.22) [64] (Table 2). Methodological shortcomings included not reporting baseline characteristics for subgroups and small sample sizes; however clinical outcomes demonstrated physiological effects consistent with laboratory and animal findings (Tables 1 and 2).

Cimicifuga racemosa

Cimicifuga racemosa was found to lower LH in two laboratory studies both examining cell cultures from ovariectomised rats [45,52] (Table 1). The mechanism occurred through competitive inhibition of oestrogen following the selective binding of oestrogen receptors (ERa) on the hypothalamus and pituitary [52]. An earlier study found contrary results for reduction of LH, however this study investigated an isolated flavonoid and suggested that other constituents may be active [37].

Three RCTs corroborate the positive fertility effects for Cimicifuga racemosa in women with PCOS, used in conjunction and when compared with the pharmaceutical Clomiphen citrate (clomiphene), [65,68,71] (Table 2). Results were reported for 441 women and show improved pregnancy rates when Cimicifuga racemosa was added to clomiphene during one menstrual cycle. In a study including women with PCOS (n = 147), pregnancy rates for the group receiving combined therapy (clomiphene 150 mg plus Cimicifuga racemosa 20 mg per day (Klimadynon®)) were 43.3% compared to 20.3% for women receiving only clomiphene [65] (Table 2). In another study using similar methodology (n = 100) pregnancy rates were 34.8% for the group treated with Cimicifuga racemosa plus clomiphene compared to 17.2% for women treated with clomiphene alone [68] (Table 2). Another study included women with PCOS and infertility (n = 100) compared Cimicifuga racemosa (Klimadynon®) and clomiphene over three months for hormone concentrations and pregnancy rates. Pregnancy rates were higher in the women in taking Cimicifuga racemosa compared to clomiphene, 14% and 8% respectively; however differences were not statistically significant. This study found significant effects for lowered luteinising hormone for women with PCOS receiving Cimicifuga racemosa compared to clomiphene (p = 0.007) [67]. Findings from clinical studies concur with laboratory and animal studies; however potential risks for bias include performance and collection bias due to lack of blinding (Table 2).

Tribulus terrestris

Two laboratory based RCT’s examined the effects of Tribulus Terrestis in rats with polycystic ovaries induced with oestradiol valerate [46,47] (Table 1). Both studies demonstrate significantly improved ovulation rates for animals treated with two doses of Tribulus terrestris extracts compared to controls. Although the endocrinological effects were not described in either study, laboratory findings of ovulation induction are supported by the clinical findings of elevated FSH following treatment with Tribulus terrestris [56] (Table 2). A prospective, observational clinical trial examined the endocrine effects of Tribulus terrestris 750 mg per day, over five days in eight healthy women (aged 28–45). A significant increase in mean serum FSH concentration from 11 mIU/ml before treatment to 17.75 mIU/ml following treatment (P < 0.001) was demonstrated. Pretreatment FSH levels returned following cessation of treatment (Table 1). Another clinical study evaluated the equivalence of Tribulus terrestris (Tribestan®) and pharmaceuticals for ovulation induction in women with oligo/anovular infertility (n = 148), [60]. During the three month follow up, ovulation rates were highest with epi-mestrol (74%), followed by Tribulus terrestris (60%), clomiphene (47%) and cyclofenil (24%). However, the evidence for Tribulus terrestris should be interpreted...
with caution due to risks for bias in clinical studies. One study was uncontrolled with a small number of healthy participants [56], the second study did not report baseline characteristics, methods for allocation to treatment groups and data were not statistically analysed [60] (Table 1).

**Glycyrrhiza spp**
Androgen lowering effects for *Glycyrrhiza spp.* have been demonstrated in one laboratory study examining hormone concentration in female rats (*Glycyrrhiza uralensis*), [53] and corroborated in two clinical trials, one including healthy women [55] and the other including women with PCOS (*Glycyrrhiza glabra*) [54] (Table 1). The animal study reported significantly reduced free and total testosterone and increased oestradiol in sterilised rats and no hormonal changes in oophrectomised rats. The authors conclude that the hormonal effects occurred primarily in the ovary via enhanced aromatisation of testosterone to 17-beta oestradiol. The investigators also observed significantly increased oestradiol. There were no changes to FSH or LH in androgen sterilised or oophrectomised rats [53].

Another animal study examined the effects of *Glycyrrhiza uralensis* on the morphological features of polycystic ovaries using immunohistochemistry [50] (Table 1). This study demonstrated significantly increased ovulation rates by the number of corpus luteum in polycystic ovaries compared with controls. The authors propose that the mechanism of effect for *Glycyrrhiza uralensis* was competitive inhibition of oestrogen at oestrogen receptor sites, limiting the production of nerve growth factor (NGF), its neurotropic effects and inhibition of sympathetic neurological involvement in the pathogenesis of polycystic ovaries.

Two clinical studies examined the androgen lowering effects of *Glycyrrhiza Glabra*. A single arm clinical trial demonstrated reduced testosterone in healthy women aged 22–26 years (n = 9) over two menstrual cycles. Treatment with *Glycyrrhiza glabra*, 7 grams per day reduced testosterone from 27.8(±8.2) to 17.5 (±6.4), p < 0.05 [55]. Another single arm clinical trial investigated the effects of *Glycyrrhiza glabra* in women with PCOS, (n = 32). *Glycyrrhiza glabra* 3.5 g per day was added to anti-androgen pharmaceutical treatment, Spirinolactone 100 mg/day over two menstrual cycles. An unwanted side effect for Spirinolactone was the flare of androgens during the initial phase of treatment. This study demonstrated reduced concentrations of testosterone during the first four days of treatment at 103 ± 29 ng/d in the Spirinolactone group compared to 91 ng/d (±19) when combined with *Glycyrrhiza glabra* (p < 0.05) [54] (Table 1). Consistent laboratory and clinical outcomes were demonstrated however limitations included design shortcomings. Both clinical studies were open label observational design with small sample sizes; one included healthy participants. Rigorous studies are needed to confirm the androgen lowering effects of *Glycyrrhiza spp.* in hyperandrogenism and PCOS.

Results for *Glycyrrhiza Spp.* (and indeed any herbal ingredient) were complicated in this case by the variation in herbal extraction processes and subsequent variability in chemical profiles of the herbal ingredients. The laboratory studies of the herbal material were based on aqueous extracts of crude material whilst the clinical studies were based on ethanol extracts. Despite variability in the herbal extraction methods, both laboratory and clinical studies demonstrated anti-androgenic effects.

**Paeonia lactiflora and glycyrrhiza uralensis**
One laboratory study and two clinical investigations provided evidence for the two herb combination, *Glycyrrhiza uralensis* and *Paeonia lactiflora* [53,58,59] (Table 1). An animal study found significant reductions in free and total testosterone following exposure to the combination [53] (Table 1). These findings were supported in two open label clinical trials including women with PCOS (n = 34) [59] and women with hyperandrogenism (n = 8) [58]. Both trials examined the effects on androgens for the aqueous extract TJ-68 (equal parts *Glycyrrhiza uralensis* and *Paeonia lactiflora*), 75 grams per day for 24 weeks and 5–10 grams per day for 2–8 weeks respectively. In the trial including women with PCOS, mean serum testosterone was significantly reduced from 137.1 ng/dL (±27.6) to 85.3 ng/dL (±38), p < 0.001 at four weeks of treatment [59]. Similar effects were observed in the women with oligomenorrhoea and hyperandrogenism which showed serum testosterone reduced from 50-160 ng/dL prior to treatment to less than 50 ng/dL [58]. However statistical significance was not reached due to the small sample size despite positive outcomes in seven out of eight participants (Table 1).

**Paeonia lactiflora and cinnamomum cassia**
*Paeonia lactiflora* combined with *Cinnamomum cassia* in a preparation called Unkei-to was investigated in an in-vitro study for ovarian production of 17-beta-oestradiol and progesterone, [42] (Table 1). Granulosa cells obtained from women undergoing IVF were examined for steroid hormone concentration following incubation with different doses over 48 hours. Oestradiol was significantly increased (p < 0.01) following exposure to doses of 0.3 ug/ml of Unkei-to. Supporting clinical evidence was found in one clinical trial of 157 infertile women aged 17–29 years, including a subgroup of 42 women with hyper-functioning (PCOS) oligo/amenorrhoea. Treatment with Unkei-to, 7.5 grams per day for eight weeks, demonstrated significant reductions of mean LH in the PCOS sub-group of 49.7% (±15.3). Ovulation was confirmed in 30 out of 42
oligo/amenorrheic women [57] (Table 1). Limitations however include findings based on sub-group comparisons without description of subgroup baseline characteristics (other than oligomenorrhea). Although the same aqueous extract intervention was investigated in preclinical and clinical studies, it contained additional herbal extracts and it was irrational to attribute hormonal effects to *Paeonia lactiflora* and *Cinnamomum cassia*.

### Cinnamomum cassia

An animal study compared the effectiveness of *Cinnamomum cassia* and the pharmaceutical Metformin on hormone concentration in rats with PCOS [48] (Table 1). Both interventions demonstrated significant improvements compared to controls at 15 days for measures of testosterone ng/ml (control 0.747 ± 0.039; metformin 0.647 ± 0.027; *Cinnamomum cassia* 0.625 ± 0.029; LH ng/ml (control 7.641 ± 0.267; metformin 6.873 ± 0.214; *Cinnamomum cassia* 6.891 ± 0.221) and insulin resistance (HOMA-IR) (control 10.018 ± 0.217; metformin 7.067 ± 0.184 *Cinnamomum cassia* 8.772 ± 0.196) (p < 0.05) [48]. The metabolic effects for *Cinnamomum cassia* were further demonstrated in overweight women with oligo/amenorrhea and PCOS in a placebo controlled RCT [66] (Table 2). However, although the RCT had low risks for bias, it was a pilot study primarily investigating feasibility. Outcomes were promising for metabolic profile in PCOS however the sample size was small and the authors recommended further studies.

### Summary of results

This review includes 18 preclinical laboratory based studies and 15 clinical trials. We found reproductive endocrine effects in oligo/amenorrhea, hyperandrogenism and/or PCOS for six herbal medicines. The quality of evidence, as determined by the volume of pre-clinical studies and the methodological quality of clinical trials, was highest for the herbal medicines *Vitex agnus-castus*, *Cimicifuga racemosa* and *Cinnamomum cassia*, for which there were laboratory and/or animal studies demonstrating endocrine mechanisms of action consistent with clinical outcomes shown in RCT’s with low risks for bias. However, replicated RCT data was only found for one herbal medicine, *Cimicifuga racemosa*.

Evidence for *Tribulus terrestris*, *Glycyrrhiza spp.* alone and in combination with *Paeonia lactiflora* and *Paeonia lactiflora* with *Cinnamomum cassia* was limited by the volume of laboratory and animal studies, with only one to two studies found for each herb or herbal combination. There was supporting clinical data, however many were small single arm, open label studies measuring endocrine effects in healthy women. Evidence for these herbal medicines is preliminary and in an emergent phase.

### Discussion

This review synthesises the evidence for mechanisms of effect for herbal medicine in oligo/amenorrhoea, hyperandrogenism and PCOS. Laboratory, animal and clinical studies demonstrate that the herbal medicines *Vitex agnus-castus*, *Cimicifuga racemosa* and *Tribulus terrestris* initiate endocrine effects in the pituitary as measured by lowered prolactin and LH and raised FSH. Four herbal medicines, *Tribulus terrestris*, *Glycyrrhiza spp.* (alone and in combination with *Paeonia lactiflora*), *Paeonia lactiflora* (in combination with *Cinnamomum cassia*) and *Cinnamomum cassia* demonstrated morphological changes in polycystic ovaries and steroidogenesis, including reduced ovarian volume and cysts, lowered androgens, improved insulin sensitivity and increased oestradiol.

Clinical investigations found no adverse effects for the six herbal medicines included in this review (Table 2). A comparative study investigating the pharmaceutical Bromocriptine and the herbal medicine *Vitex agnus-castus* found no side effects associated *Vitex agnus-castus* compared to 12.5% of participants taking Bromocriptine reporting nausea and vomiting [63]. No studies comparing the effectiveness for herbal medicines and the oral contraceptive pill in PCOS, oligo/amenorrhea and hyperandrogenism were found.

Herbal medicine may present a treatment option for women with oligo/amenorrhea, hyperandrogenism and PCOS as an adjunct or alternative treatment to pharmaceuticals with a high degree of acceptability by women with PCOS [6]. Preliminary evidence for equivalent treatment effects were found for the two pharmaceuticals and three herbal medicines. These were bromocriptine, in the management of hyperprolactinaemia and *Vitex agnus-castus* and clomiphene for infertility and ovulation induction and *Cimicifuga racemosa* and *Tribulus terrestris*. Herbal medicine had positive adjunct effects with the pharmaceuticals Spirinolactone in the management of hyperandrogenism (*Glycyrrhiza Spp.*), and clomiphene for PCOS related infertility (*Cimicifuga racemosa*). It is important however to highlight that evidence was provided by a limited number of clinical studies, some with significant risks for bias; particularly *Tribulus terrestris*, *Glycyrrhiza glabra* alone and in combination with *Paeonia lactiflora* and *Paeonia lactiflora* in combination with *Cinnamomum cassia*.

Selection of herbal medicines for the management of PCOS often includes the combined prescription of *Glycyrrhiza spp.* and *Paeonia lactiflora* [72-75]. We found preliminary evidence for this combination for hyperandrogenism only, and the evidence was more robust for *Glycyrrhiza spp.* alone than when combined with *Paeonia lactiflora*. Comparatively, our findings for the combination of *Paeonia lactiflora* and *Cinnamomum cassia* demonstrated no change in androgen concentration, suggesting that the anti-
androgen activity in the *Glycyrrhiza* spp. and *Paeonia lactiflora* combination more likely attributable to *Glycyrrhiza* spp. However our findings may be complicated by the aqueous extraction methods used in the *Paeonia lactiflora* and *Cinnamomum cassia* combination and the preclinical studies into the *Glycyrrhiza* spp. and *Paeonia lactiflora* combination. More research into the antiandrogen effects of the combination *Glycyrrhiza* spp. and *Paeonia lactiflora* is needed to clarify the antiandrogen mechanism particularly if this herbal combination remains cornerstone herbal management for hyperandrogenism.

This review has some limitations. We used a methodological approach which was deductive and not consistent with traditional rationale for herbal selection. Our inclusion criteria for clinical studies were specific and relied upon our identification of herbal medicines with preclinical (laboratory based) evidence explaining the mechanisms of reproductive endocrinological effects in oligo/amenorrhoea, hyperandrogenism and PCOS. Clinical studies were excluded from this review due to the absence of evidence for whole herbal extracts. This was the case for *Camellia sinensis* (green tea) for which only one laboratory study investigated the effects of injecting epigallocatechin, a catechin found in green tea in animals [76]. High quality clinical evidence for *Camellia sinensis* was not presented in this review due to the absence of pre-clinical data explaining the mechanism for effect for the whole herbal extract [77]. *Mentha spicata* (spearmint) was another herbal medicine excluded from this review despite the availability of high quality clinical evidence demonstrating testosterone lowering effects in women with PCOS [78]. We found no laboratory evidence describing the mechanism of action for *Mentha spicata* in hyperandrogenism. *Camilla sinensis* and *Mentha spicata* are examples of herbal medicines excluded from this review due to not meeting the inclusion criteria. Studies investigating western herbal medicines excluded from this review are provided in Tables 3, 4 and 5.

Our search strategy may have restricted access due to limited search terms. We didn’t include alternative spelling of oestrogen and additional search terms for herbal medicine could have been included to increase sensitivity of the search.

This study synthesises the evidence for reproductive endocrine effects for six whole herbal medicine extracts that may be used to treat PCOS and associated oligo/amenorrhoea and hyperandrogenism. The findings were intended to add to clinicians understanding for the mechanisms of action for herbal medicine for treatment in these common conditions and reveal herbal medicines with reproductive endocrinological effects, currently demonstrated in scientific literature.

**Conclusions**

Preclinical and clinical studies provide preliminary evidence that six herbal medicines may have beneficial effects for women with oligo/amenorrhoea, hyperandrogenism and PCOS. The quality of the evidence is variable and strongest for *Vitex agnus-castus* and *Cimicifuga racemosa* in the management of oligo/amenorrhoea and infertility associated with PCOS; and *Cinnamomum cassia* for improving metabolic hormones in PCOS. Evidence for *Tribulus terrestris*, *Glycyrrhiza* spp. alone and in combination with *Paeonia lactiflora* and *Paeonia lactiflora* combined with *Cinnamomum cassia* is promising but in an emergent phase. Further investigations into the mechanisms of effect for herbal extracts are needed to complete our understanding of the reproductive endocrinological effects for herbal medicine for these common conditions.
