Abstract

**Background:** *Crocus sativus* L. (saffron) is used in folk medicine, for example as an antiedematogenic agent. We aimed to evaluate the antinociceptive and anti-inflammatory activity of saffron extracts in mice.

**Results:** We used aqueous and ethanolic maceration extracts of *Crocus sativus* L. stigma and petals. Antinociceptive activity was examined using the hot plate and writhing tests. The effect of extracts against acute inflammation was studied using xylene induced ear edema in mice. The activity of the extracts against chronic inflammation was assessed by formalin-induced edema in the rat paw. In the hot plate tests, intraperitoneal injection of both extracts showed no significant antinociceptive activity in mice. The extracts exhibited antinociceptive activity against acetic acid induced writhing. Naloxone partially blocked only the antinociceptive activity of the stigma aqueous extract. Only the stigma extracts showed weak to moderate effect against acute inflammation. In chronic inflammation, both aqueous and ethanolic stigma extracts, as well as ethanolic petal extract, exerted anti-inflammatory effects.

**Conclusions:** We conclude that aqueous and ethanolic extracts of saffron stigma and petal have an antinociceptive effect, as well as acute and/or chronic anti-inflammatory activity.

Background

*Crocus sativus* L. (Iridaceae), commonly known as saffron is used in folk medicine for various purposes such as an aphrodisiac, antispasmodic and expectorant [1]. Modern pharmacological studies have demonstrated that saffron extracts have antitumour [2–4], radical scavenger, hypolipidaemic [5], anticonvulsant effects [6] and improve activity on learning and memory [5,7].

Chemical studies on *C. sativus* have shown the presence of constituents such as crocin, crocetin, safranal and picrocrocin [8–10]. Among the constituents of saffron extract, crocetin is mainly responsible for these pharmacological activities [5].

In traditional medicine, the stigma of this plant is used as an antiedematogenic remedy [1]. The aim of this study was to validate the anti-inflammatory and antinociceptive effect of the saffron stigma and petal extracts.
Results
The maximum non-fatal doses of stigma aqueous and ethanolic extracts were 0.8 g/kg and 2 g/kg (i.p.), respectively. The maximum non-fatal doses of petal aqueous and ethanolic extracts were 3.6 g/kg and 8 g/kg (i.p.), respectively. LD₅₀ values of the petal aqueous and ethanolic extracts were 6.67 g/kg, i.p. (4.95, 8.99) and 9.99 g/kg, i.p. (8.13, 12.28), respectively.

Phytochemical screening of the extracts indicated the presence of flavonoids, tannins and anthocyanins in the petal aqueous and ethanolic extracts. Alkaloids and saponins were found in the stigma aqueous and ethanolic extracts (Table 1).

Table 1: Phytochemical screening of Crocus sativus petal and stigma aqueous and ethanolic extracts.

| Extract  | Alkaloids | Flavonoids | Tannins | Saponins | Anthocyanins |
|----------|-----------|------------|---------|----------|--------------|
| Petal    |           |            |         |          |              |
| Aqueous  | -         | +          | +       | -        | +            |
| Ethanolic| -         | +          | +       | -        | +            |
| Stigma   |           |            |         |          |              |
| Aqueous  | +         | -          | -       | +        | -            |
| Ethanolic| +         | -          | -       | +        | -            |

The aqueous and ethanolic extracts of C. sativus petal and stigma significantly reduce the number of mouse abdominal constrictions induced by a 0.7% acetic acid solution in a dose dependent manner (P<0.001, except for the dose of 0.36 g/kg of aqueous stigma which was P<0.01). Morphine and diclofenac induced a protection against abdominal constrictions (P<0.001). Naloxone, (2 mg/kg, s.c.) pretreatment after i.p. injection of the extracts practically did not inhibit the antinociceptive activity of both extracts (figures 1, 2, 3, and 4). Only, the antinociceptive effect of aqueous stigma extract, 0.32 g/kg, was partially blocked by naloxone (figure 3). Naloxone completely antagonized the antinociceptive activity of morphine.

In hot plate test, aqueous (1.4, 2.5 and 3.6 g/kg, i.p.) and ethanolic (0.8, 3.2 and 5.6 g/kg, i.p.) petal extracts showed no significant antinociceptive activity (P>0.05) (figures 5 and 6). The aqueous (0.32, 0.56 and 0.8 g/kg, i.p.) and ethanolic (0.8, 1.4 and 2 g/kg, i.p.) stigma extracts also exerted no significant analgesic activity (P>0.05) (figures 7 and 8). Morphine, a positive reference, (10 mg/kg, i.p.) showed significant analgesic effect in the hot-plate test beginning 30 min after treatment (P<0.001). In the xylene induced ear edema, the aqueous and ethanolic extracts of petal showed no significant anti-inflammatory activity but diclofenac and dexamethasone reduced the edema about 50% (Tables 2 and 3). In higher doses, the aqueous (0.56 g/kg, P<0.05; 0.8 g/kg, P<0.01) and ethanolic (1.4 g/kg, P<0.05; 2 g/kg, P<0.05) extracts of stigma showed significant activity against the acute inflammation (Tables 4 and 5).

In the chronic inflammation (formalin test), the aqueous petal extracts did not exhibit significant anti-inflammatory activity (P>0.05) but the ethanolic petal extract showed significant activity (figure 9). Both extracts of the stigma exerted significant anti-inflammatory activity (figure 10). In diclofenac and the ethanolic stigma extract (1.4 g/kg), the hind paw edema of rat disappeared after 6 days (P<0.001) (figure 10). Diclofenac as well as the aqueous (0.8 g/kg) and ethanolic stigma extract (1.4 g/kg) showed anti-inflammatory effect on day one (P<0.05) (figure 10). On days 4 and 5, both diclofenac and the extracts did not demonstrate anti-inflammatory activity (P>0.05).

Discussion
The present results indicate that aqueous and ethanolic extracts of C. sativus petal and stigma have antinociceptive activity in chemical pain tests. The stigma extracts showed activity against acute and chronic inflammation. The petal ethanolic extract showed anti-inflammatory activity in the chronic inflammatory test.

In respect to LD₅₀ values and maximum non-fatal doses, the stigma extracts were more toxic than the petal extracts. LD₅₀ values of aqueous and ethanolic stigma extracts have been reported as 1.6 g/kg, i.p. (1.16, 2.22) and 3.38 g/kg, i.p. (2.55, 4.52) in mice [6]. According to a toxicity classification [11], stigma and petal extracts are "relatively toxic" and "low toxic", respectively. Treatment with the C. sativus extract also significantly prolonged the life span of cisplatin-treated mice almost three-fold [12]. Toxicity studies showed that the hematological and biochemical parameters were within normal range with saffron extract [2].

As preliminary phytochemical results indicated, it could be suggested that the antinociceptive and anti-inflammatory effects of the petal extracts may be due to their content of flavonoids, tannins and anthocyanins. Other studies have demonstrated that various flavonoids such as rutin, quercetin, luteolin, hesperidin and biflavonoids produced significant antinociceptive and/or anti-inflammatory activities [13–16]. There are few reports on the role of tannins in antinociceptive and anti-inflammatory activities [17]. Recently, it has been shown that crocins, Crocus glycosides, exhibited an anti-inflammatory effect in some models of inflammation [18].
In the present study, morphine, a centrally acting analgesic drug, produced an inhibitory effect on the nociceptive response in the hot plate test, a central antinociceptive test [19], while the aqueous and ethanolic extracts showed no antinociceptive activity in this test. Thus, the extracts may not act via central mechanisms, although agents that alter the motor performance of animals may increase the latency time on the hot plate test without acting on the central nervous system [19]. Antinociceptive activity of opioid agonists, opioid partial agonists, and non-steroidal anti-inflammatory agents can be determined by the writhing test [20]. It has also been shown that some plants such as Hunteria zeylanica [21] and Ocotea suaveolens [22] decrease stretching induced by acid acetic acid but have no effect on heat-induced pain. The association of both antinociceptive activity and moderate anti-inflammatory effect observed with the extracts has also been shown in non-steroidal anti-inflammatory drugs (NSAIDs). It is a well-established fact that NSAIDs exert their analgesic and anti-inflammatory activity by the inhibition of cyclo-oxygenase activity [23]. As the antinociceptive activity of most extracts in the writhing test was not inhibited by naloxone, the extracts may not act via opioid receptors and may exert their activity via a peripheral mechanism. The stigma extracts and the ethanolic petal extracts significantly diminished in a dose dependent way the induced paw edema in rats. The extracts were able to reduce the inflammation in acute and chronic phases.

It is concluded that saffron stigma and petal aqueous and ethanolic maceration extracts have antinociceptive effects in chemical pain tests and have acute and/or chronic anti-inflammatory activity. The antinociceptive and anti-inflammatory effects of the extracts may be due to their content of flavonoids, tannins, anthocyanins, alkaloids and saponins. However, the chemical constituents and mech-
anism(s) responsible for the pharmacological activities remain to be investigated.

Materials and Methods

Animals
Male and female albino mice 25–30 g and Wistar rats weighing 150–210 g were obtained from a random bred colony in the animal house of Mashhad University of Medical Sciences. Animals were housed in colony room 12/12 hr light/dark cycle at 21 ± 2°C and had free access to water and food.

Plant material
Plants were collected from Torabat Hydarieh (in south of Khorassan province, I.R. of Iran) in October 1998 and dried in shadow and ground. The C. sativus L. was identified by Ferdowsi University (Ms. Molaei) and voucher samples were preserved for reference in the herbarium of School of Pharmacy, Mashhad, IR. Iran (143-0319-1).

Preparation of extracts
The powder of stigma or petal was extracted using maceration with ethanol or water. The powdered plant was macerated in water or ethanol (80 %, v/v) for 3 days and, subsequently, the mixture was filtered and concentrated under reduced pressure at 40°C. The yield (w/w) of aqueous and ethanolic extracts of stigma was 50.8% and 56.6%, respectively. The yield (w/w) of aqueous and ethanolic extracts of petal was 15.5% and 19%, respectively. The extracts were dissolved in normal saline.

Phytochemical screening
Phytochemical screening of the extract was performed using the following reagents and chemicals: Alkaloids with Dragendorff’s reagent, flavonoids with the use of Mg and HCl; tannins with 1% gelatin and 10% NaCl solutions and saponins with ability to produce suds [24].
The maximum non-fatal dose (MNFD) and acute toxicity

Different doses of the extracts were injected to separate groups of five animals. After 48 h, the highest dose that did not induce any mortality was considered as the maximum non-fatal dose. The number of deaths was counted at 48 h after treatment. LD50 values and the corresponding confidence limits (CL, 95%) were determined by the Litchfield and Wilcoxon method (PHARM/PCS Version 4). Doses of 10, 40 (50), 70 and 100 % MNFD were chosen for most tests. Lower doses were found to be effective in the writhing test.

Antinociceptive study

Hot-plate test

The hot-plate test was assessed on groups of 8 mice. The temperature of a metal surface was maintained at 55 ± 0.2°C. Latency to a discomfort reaction (licking paws or jumping) was determined before and after drug administration. The cut-off time was 20 s. The latency was recorded before and 30, 60, 120, 150 and 240 min following intraperitoneal administration of the agents. The prolongation of the latency times compared with the values of the control was used for statistical comparison. Control received normal saline (10 ml/kg, i.p.) and morphine (10 mg/kg, i.p.) was used as reference drug [25].

Writihing test

Groups of 8 mice were used for controls and test mice. One hour after the administration of the extract, the mice were given an intraperitoneal injection of 0.7% v/v acetic acid solution (volume of injection 0.1 ml/10 g). The mice were placed individually into glass beakers and five min were allowed to elapse. The number of writhes produced in these animals was counted for 30 min. For scoring purposes, a writhes is indicated by stretching of the abdomen with simultaneous stretching of at least one hind limb. Control received normal saline (10 ml/kg, i.p.), diclofenac (10 mg/kg, i.p.) and morphine (10 mg/kg, i.p.) were used as reference drugs. Naloxone (2 mg/kg, s.c.) was administered 15 min prior to the extracts or morphine injections [25].

Anti-inflammatory study

Xylene-induced ear edema

Mice were divided into groups of seven. Thirty minutes after i.p. injection of the extract, diclofenac and dexametha-
sone, 0.03 ml of xylene was applied to the anterior and posterior surfaces of the right ear. The left ear was considered as control. Two hours after xylene application, mice were killed and both ears were removed. Circular sections were taken, using a cork borer with a diameter of 7 mm, and weighed. The increase in weight caused by the irritant was measured by subtracting the weight of the untreated left ear section from that of the treated right ear sections. The formula for computing percent inhibition was: average writhes in the control group (normal saline) minus writhes in the drug group divided by writhes in the control group times 100%. Control received normal saline (10 ml/kg, i.p.), diclofenac (10 mg/kg, i.p.) and dexamethasone (15 mg/kg, i.p.) were used as reference drugs [25].

**Formalin induced inflammation**

Rats were divided into groups of six. The inflammation was produced by subaponeurotic injection of 0.1 ml of 2% formaldehyde in the right hind paw of the rats on the first and third day. The animals were treated daily with the extracts or diclofenac intraperitoneally for 10 days. The daily changes in paw size were measured by wrapping a

| Treatment                  | Dose   | Ear swelling (mg) | Inhibition (%) |
|---------------------------|--------|-------------------|----------------|
| Control                   | 10 ml/kg | 7.6 ± 0.6         | -              |
| Diclofenac                | 15 mg/kg | 3.9 ± 0.4***      | 49.1           |
| Dexamethasone             | 15 mg/kg | 3.2 ± 0.3***      | 58.2           |
| Extract                   | 1.4 g/kg | 6.8 ± 0.3         | 11.7           |
| Extract                   | 2.5 g/kg | 6.4 ± 0.4         | 15.9           |
| Extract                   | 3.6 g/kg | 6.3 ± 0.3         | 17.2           |

The increase in weight caused by the irritant (xylene) was measured by subtracting the weight of the untreated left ear section from that of the treated right ear sections. Values are the mean ± S.E.M. for 7 mice, ***P<0.001, compared to control (normal saline), Tukey-Kramer.
piece of cotton thread round the paw and measuring the circumference with a meter rule [26].

### Materials
The following reagents were used: morphine and dexamethasone (Dam Pakhsh, I.R. Iran), naloxone hydrochloride (Tolid Daru, I.R. Iran), diclofenac (Zahrawi, I.R. Iran), acetic acid, xylene and formaldehyde (Merck).

### Statistical analysis
The data were expressed as mean values ± S.E.M. and tested with analysis of variance followed by the multiple comparison test of Tukey-Kramer.
Figure 10
Effect of stigma Crocus sativus aqueous and ethanolic extracts and diclofenac on formaldehyde induced arthritis in hind paw of rats. The inflammation was produced by subaponeurotic injection of 0.1 ml of 2% formaldehyde in the right hind paw of the rats on the first and third day. The animals were treated daily with the extracts or diclofenac intraperitoneally for 10 days. All agents were administered intraperitoneally.
