The role of sheep ked (*Melophagus ovinus*) as potential vector of protozoa and bacterial pathogens

Joanna Werszko¹*, Marek Asman², Joanna Witecka², Żaneta Steiner-Bogdaszewska¹, Tomasz Szewczyk¹, Grzegorz Kuryło³, Konrad Wilamowski³ & Grzegorz Karbowiak¹

The sheep ked (*Melophagus ovinus*) hematophagous insect may act as a potential vector of vector-borne pathogens. The aim of this study was to detect the presence of *Trypanosoma* spp., *Bartonella* spp., *Anaplasma phagocytophilum* and *Borrelia burgdorferi* s.l. in sheep ked collected from sheep in Poland. In total, *Trypanosoma* spp. was detected in 58.91% of *M. ovinus*, whereas *Bartonella* spp. and *B. burgdorferi* s.l. were found in 86.82% and 1.55% of the studied insects, respectively. *A. phagocytophilum* was not detected in the studied material. In turn, co-infection by *Trypanosoma* spp. and *Bartonella* spp. was detected in 50.39%, while co-infection with *Trypanosoma* spp. and *Bartonella* spp. and *B. burgdorferi* s.l. was found in 1.55% of the studied insects. The conducted study showed for the first time the presence of *B. burgdorferi* s. l. in *M. ovinus*, as well as for the first time in Poland the presence of *Trypanosoma* spp. and *Bartonella* spp. The obtained results suggest that these insects may be a potential vector for these pathogens, but further-more detailed studies are required.

The family Hippoboscidae (Diptera) is a group of blood-sucking flies of veterinary importance that parasitize on mammals and birds. Worldwide, the fauna of Hippoboscinae consists of more than 213 species, 21 genera and three subfamilies: (Ornithomyinae, Hippoboscinae and Lipopteinae)¹². In Europe, about 30 species of hippoboscid have been described, of which 10 species are found in Poland²³. The sheep ked (*Melophagus ovinus*) is a blood-sucking wingless ectoparasite of sheep. Their life-cycle consists of three stages: larva, pupa and adult, and occurs in the fleece of the sheep host and can be carried from one sheep to another by direct contact⁴. Although the sheep ked parasitizes mainly sheep, their incidental occurrence has also been reported in red fox, rabbit and the European bison⁴⁵. This species of flies occurs in North America, Oceania, Asia, China, Africa and Europe⁴⁶. The sheep keds have an economic impact by reducing the production of meat, milk and the wool of sheep, and the infestation of sheep also has harmful effects, such as: weight loss, anemia, anxiety and reduction in wool growth. In addition, skin damage due to abrasion and scratching can lead to secondary microbiological infections⁴. The sheep ked has been reported to be responsible for the transmission of zoonotic pathogens, such as: *Bartonella* spp., *Anaplasma plasmodium* spp., bluetongue virus, border disease virus (BDV), Rickettsia spp., *Trypanosoma* spp.⁶–¹³. The occurrence of arthropod-borne pathogens in *M. ovinus* has not yet been studied in Poland.

Trypanosomes (genus *Trypanosoma*, family Trypanosomatidae, order Kinetoplastea), are flagellated protozoa with a worldwide distribution and have been isolated from the gut of sheep ked and the blood of sheep¹⁴. Due to the developmental mode, it belong to the Stercorarian group. The infection of trypanosomes in the mammalian host takes place through damaged skin or mucous membranes when the trypanosomes leave the insect organism with the faeces¹⁴. Trypanosomiasis in animals are usually subclinical, although anaemia, leucocytosis, weight loss, neonate death and decreased milk production have been noted¹⁵.

*Anaplasma phagocytophilum* causes granulocytic anaplasmosis in humans (HGE) as well tick-borne fever in ruminants, equine anaplasmosis in horses, and severe febrile diseases in dogs and cats⁶⁶. It is Gram-negative intracellular bacteria of the family Anaplasmataceae that grow and multiply in the membrane-bound vacuoles of vertebrate and invertebrate host cells¹⁷. The disease is multi-systemic and causes lethargy, ataxia, loss of

¹Witold Stefański Institute of Parasitology, Polish Academy of Sciences, Twarda 51/55, 00-818 Warsaw, Poland. ²Department of Parasitology, Faculty of Pharmaceutical Sciences in Sosnowiec, Medical University of Silesia, Jedności 8, 41-218 Sosnowiec, Poland. ³Institute of Forest Sciences, Faculty of Civil Engineering and Environmental Sciences, Białystok University of Technology, Wiejska 45e, 15-351 Białystok, Poland. ⁴email: joanna.werszko@gmail.com
appetite, and weak or painful limbs. The cells most commonly infected are neutrophilic granulocytes. Humans can be the host, and the animal reservoir for *A. phagocytophilum* depends on the geographic region and includes many animal species, including wild animals such as rodents, carnivores, deer and domestic animals, such as cattle, goats, and sheep18–20. Molecular studies based on the 16S rRNA gene, two different genetic variants of *A. phagocytophilum* have been described. The AP-ha strain is pathogenic to both humans and animals, while the AP -variant 1 strain is infectious to animals but not to humans21,22. In Europe, zoonotic reservoirs of human *A. phagocytophilum* strains are wild boar, the hedgehog, and possibly carnivores23,24. The *Ixodes ricinus* tick is a primary vector of this bacteria, but their presence has been also confirmed in deer keds (*Lipoptena cervi*) nor in containing more than one subspecies28. The clinical manifestations of human bartonellosis depend on the species *Bartonella*, two (*B. burgdorferi s.l.* complex consist of 22 genospecies, of which 11 are circulating in Europe and five of them, namely *B. afzelii*, are pathogenic to humans and associated with Lyme disease31,32. Blood-sucking flies, such as the deer fly, horse fly and flea, have been found to be infected with *B. burgdorferi* s.l. in Europe and North America33,34. These pathogens have been described recently in sheep ked in China9.

In the current study, a molecular screening was conducted of sheep keds for the presence of *Trypanosoma* spp. *Anaplasma* spp. *Bartonella* and *B. burgdorferi* s.l. pathogens in sheep ked collected from a sheep farm near the Białowieża Primeval Forest in north-eastern Poland. To the best of the authors’ knowledge, this for the first time in Poland the presence of a protozoan (*spp.*) and bacteria (*spp.* and *B. burgdorferi s.l.*) can co-infect sheep ked (*Melophagus ovinus*).

**Results**

In total, 129 *M. ovinus* (♀ 69 ; 60 ♂) were collected from sheep (Fig. 1) The presence *Trypanosoma* spp. was detected in 76 of the 129 (58.91%) studied insects. In turn, *Bartonella* spp. was found in 122 of the 129 (86.82%) flies. The presence of *B. burgdorferi* s.l. was detected in 2 of the 129 (1.55%) sheep keds, whereas no *A. phagocytophilum* was detected in the tested group of insects. The positivity to protozoan and bacterial pathogens DNA among female and male *M. ovinus* from different locations is given in Table 1. Co-infection with the two pathogens *Trypanosoma* spp. and *Bartonella* spp. was detected in 65 of the 129 (50.39%) *M. ovinus*, whereas co-infection with *Trypanosoma* spp. and *Bartonella* spp. and *B. burgdorferi* s.l. was detected in only 2 of the 129 (1.55%) sheep keds (Fig. 2). In the current study, *A. phagocytophilum* was not detected in the tested group of flies.

Sequence analysis showed that four partial rpoB gene sequences of *Bartonella* spp. (Gen Bank Accession No., MW929188, MW929189, MW929190, MW929191) were identical to each other and showed 100% identity with *Bartonella melophagi* from sheep ked from the USA (EF605288). In total, eight partial 18S rDNA sequences of *Trypanosoma* spp. were obtained in the current study, three of which (Acc. No., MZ2014571, MZ2014572, MZ2014565) shared 100% similarity with *Trypanosoma melophagium* from *M. ovinus* in the United Kingdom and Croatia (FN666409, HQ664912). While the other five sequences (Acc. No., MZ2014566, MZ2014567, MZ2014568, MZ2014569, MZ2014570) showed 100% identity with *Trypanosoma* spp. from *Lipoptena fortisitosa* in Poland (MT393991). Analysis of two partial fla B gene nucleotide sequences of *B. burgdorferi* s.l. (GenBank Acc. No., MW929186, MW929187) obtained in this study showed that they were identical to each other, and shared 100% similarity with *B. burgdorferi* strains from *Ixodes ricinus* ticks in Poland (MK604273, MK604272, MF150052, KX64620, KF422802, HM345911), Switzerland (KF422803) and Serbia (AB189460) and with *B. burgdorferi* isolates obtained from the human serum of a patient with Lyme in the Czech Republic (FJ231333–FJ231335). This result confirm the presence of strain typical for Middle Europe. Moreover, the presence were also identical with *B. burgdorferi* from cotton mouse (*Peromyscus gossypinus*) from the USA (EU220782).

Statistical comparisons (Table 2) revealed that there were three significant associations between variables, i.e., for prevalence of *Trypanosoma* spp. on *M. ovinus* and sampling location (*X^2^ = 51.8768, p ≤ 0.01) and for prevalence of any of examined pathogens on *M. ovinus* and sampling location (*X^2^ = 15.6845, p ≤ 0.01) as well as for prevalence of *Bartonella* spp. on *M. ovinus* and subject gender (*X^2^ = 7.864, p ≤ 0.01). All of the other associations tested were not statistically significant.

**Discussion**

The sheep keds in this study were collected in north-eastern Poland, recognized as an endemic region with a high risk of tick-borne disease infection. Despite that, in Poland there is no official data about sheep ked and their role in the transmission of pathogens and their vector competency for infectious agents. The study records for the first time in Poland the presence of a protozoan (*Trypanosoma* spp.) and bacteria (*Bartonella* spp., *B. burgdorferi* s.l., and *A. phagocytophilum*).
Figure 1. Female of *Melophagus ovinus* dorsal (A) and ventral view (B), posterior end (C) and male of *Melophagus ovinus* dorsal (D) and ventral view (E); Posterior end (F).

Table 1. Specimens of *Melophagus ovinus* analysed for *Trypanosoma* spp., *Bartonella* spp., *Borrelia burgdorferi* s.l. and *Anaplasma phagocytophilum* infection.
burgdorferi s.l. and A. phagocytophilum) in sheep ked by using molecular methods. The results obtained indicate a high positivity of Trypanosoma spp. infection among sheep ked collected in Poland (58.91%), although a higher prevalence (82.4%) of trypanosomes was recorded for St Kilda sheep ked in the Outer Hebrides, Scotland.

In the current study, a high frequency of Bartonella spp. (86.82%) in M. ovinus was found, with similar results obtained by Halos et al. who detected this bacteria in all specimens in the tested group of sheep ked in Europe. Similarly, Kumsa et al. noted a high positivity of Bartonella melophagi infection (88.6%) in sheep ked collected in Africa. Moreover, Rudolf et al. identified Bartonella melophagi in sheep keds in Central Europe, in which all investigated pools (399 specimens) of keds were positive for Bartonella spp. Similarly, in Algeria, 36.87% of sheep ked were infected with Bartonella spp.

The results obtained in the current study show for the first time in Europe evidence of Bartonella burgdorferi s.l. in M. ovinus collected from sheep. However, this bacteria was evident in only 1.5% of the studied insects. The study conducted in China by Chu et al. showed a twice as high percentage in M. ovinus infected with B. garinii and B. valaisiana (related group of Bartonella burgdorferi s.l.).

In the presented study, DNA of A. phagocytophilum was not detected in the tested group of flies, while Hornok et al. detected the presence DNA of Anaplasma ovis in all (81 specimens) of sheep ked collected from sheep in Hungary. In Algeria, 25.88% of the M. ovinus were infected by bacteria from the Anaplasmataceae family. In a study conducted by Zhang et al. the infection rates were 39.1%, 17.4%, and 9.8% for A. ovis, A. bovis, and A. phagocytophilum in M. ovinus, respectively.

The mixed infection of sheep keds with two bacterial genus, Bartonella and Anaplasma, were noted, with frequency co-infection at 18.64%. The obtained results also demonstrated that two pathogens, Trypanosoma spp. and Bartonella spp., can co-infect the same sheep ked.
The presence of *Trypanosoma* spp., *Bartonella* spp., and *B. burgdorferi* s.l. pathogens in *M. ovinus* collected from sheep may be related to their biology. The sheep ked spends its entire life cycle on the host; however, adults may circulate among the animals of the same herd, and are commonly transferred from ewes to their offspring. Hippoboscids are also likely to be mechanical vectors of infectious agents due to their blood feeding behavior. Some pathogens may be transferred from an infected host to non-infected individuals through their mouthparts, although the keds were probably infected through receiving the pathogens from sheep. However, it is interesting that keds and sheep are generally thought to be reservoirs incompetent for *B. burgdorferi* s.l. In the current study, the keds probably acquired the *B. burgdorferi* s.l. infections via co-feeding transmission when one infected *Ixodes* spp. tick infected a ked feeding nearby. At this stage of the study, it is difficult to explain this speculation. This is the first report in Europe on the detection of *B. burgdorferi* s.l. DNA in sheep keds.

Recently, the vertical transmission of *A. ovis* in sheep keds has been described. The presence of *Bartonella* DNA in all of the *M. ovinus* samples, even at the pupal stage, has been described. This provides new evidence for the potential of these flies as mechanical or biological vectors.

Due to the results of statistically significant comparisons (chi-square tests) between prevalence of *Trypanosoma* spp. and *Bartonella* spp. on *M. ovinus* versus sampling location and sex of the fly further research on this subject should be carried out.

In conclusion, this study provides the first molecular evidence of the presence of *Trypanosoma* spp. *Bartonella* spp., and *M. ovinus* on *M. ovinus* versus sampling location and sex of the fly further research on this subject should be carried out.

**Materials and methods**

Adult *M. ovinus* were collected during veterinary procedures from sheep on four sheep farms located near forest areas in north-eastern Poland, located in the villages of Rzepiska (52° 49' 56" N, 23° 33' 56" E), Nowoberezowo (52° 45' 36" N, 23° 33' 43" E), Wałbity (53° 08' 30" N, 23° 35' 25" E), and Grodek (52° 05' 48" N, 23° 39' 24" E). After collection, the flies were preserved in pure 70% ethanol for further morphological and molecular processing. Before identification, specimens were rinsed in pure water (Direct-Pure® adept Ultrapure Lab Water Systems, RepliLe Bioscience, Ltd. China) and air-dried. Gender determination and species identification were carried out using taxonomic keys, according to Borowiec under an OPTA-TECH microscope (Warsaw, Poland).

The DNA was isolated from single individuals by using a Genomic Mini AX Tissue kit (A&A Biotechnology, Gdynia, Poland), according to the manufacturer’s recommended protocol. Concentration was measured spectrophotometrically at 260/280 nm wave length. Isolated material was stored at −20°C until further molecular analysis. Pathogens in *M. ovinus* were detected by PCR and nested PCR methods.

The detection of *Trypanosoma* spp. was based on PCR amplification of a 185 rDNA gene fragment of approximately 650 bp. Two oligonucleotide primers, TrypF 150 and TrypR 800, were used, as previously described. For amplification, a 200 ng DNA template was used, and for the reactions Allegro Taq DNA Polymerase (Novazym, Poznan, Poland), was used, and to detect *Bartonella* spp., a pair of primers—1400F and 2300R—were used to detect *B. burgdorferi* s.l. DNA in sheep keds. Detection of the pathogen in *M. ovinus* is important evidence that other blood-sucking flies, including hippoboscid flies, are important candidates as potential vectors of infectious diseases.
