Abstract
We consider operator scaling $\alpha$-stable random sheets, which were introduced in Hoffmann (Operator scaling stable random sheets with application to binary mixtures. Dissertation Universität Siegen, 2011). The idea behind such fields is to combine the properties of operator scaling $\alpha$-stable random fields introduced in Biermé et al. (Stoch Proc Appl 117(3):312–332, 2007) and fractional Brownian sheets introduced in Kamont (Probab Math Stat 16:85–98, 1996). We establish a general uniform modulus of continuity of such fields in terms of the polar coordinates introduced in Biermé et al. (2007). Based on this, we determine the box-counting dimension and the Hausdorff dimension of the graph of a trajectory over a non-degenerate cube $I \subset \mathbb{R}^d$.

1 Introduction
In this paper, we consider a harmonizable operator scaling $\alpha$-stable random sheet as introduced in [11]. The main idea is to combine the properties of operator scaling $\alpha$-stable random fields and fractional Brownian sheets in order to obtain a more general class of random fields. Let us recall that a scalar valued random field $\{X(x) : x \in \mathbb{R}^d\}$ is said to be operator scaling for some matrix $E \in \mathbb{R}^{d \times d}$ and some $H > 0$ if

$$\{X(cE \cdot x) : x \in \mathbb{R}^d\} \stackrel{f.d.}{=} \{c^H X(x) : x \in \mathbb{R}^d\} \text{ for all } c > 0,$$

(1.1)
where \( f.d. \) means equality of all finite-dimensional marginal distributions and, as usual, 
\[ c^E = \sum_{k=0}^{\infty} \frac{(\log c)^k}{k!} E^k \]
is the matrix exponential. These fields can be regarded as an anisotropic generalization of self-similar random fields (see, e.g., [8]), whereas the fractional Brownian sheet \( \{ B_{H_1,\ldots,H_d}(x) : x \in \mathbb{R}^d \} \) with Hurst indices \( 0 < H_1,\ldots,H_d < 1 \) can be seen as an anisotropic generalization of the well-known fractional Brownian field (see, e.g., [13]) and satisfies the scaling property

\[
\{ B_{H_1,\ldots,H_d}(c_{1}x_1,\ldots,c_d x_d) : x = (x_1,\ldots,x_d) \in \mathbb{R}^d \}
\]
\[ f.d. \Rightarrow \{ c_{1}^{H_1} \cdots c_d^{H_d} B_{H_1,\ldots,H_d}(x) : x \in \mathbb{R}^d \}
\]

for all constants \( c_1,\ldots,c_d > 0 \). See [3,10,27] and the references therein for more information on the fractional Brownian sheet.

Throughout this paper, let \( d = \sum_{j=1}^{m} d_j \) for some \( m \in \mathbb{N} \) and \( \tilde{E}_j \in \mathbb{R}^{d_j \times d_j} \), \( j = 1,\ldots,m \) be matrices with positive real parts of their eigenvalues. We define matrices \( E_1,\ldots,E_m \in \mathbb{R}^{d \times d} \) as

\[
E_j = \begin{pmatrix}
0 & & & 0 \\
& \ddots & & \\
& & 0 & \tilde{E}_j \\
0 & & & 0 \\
\end{pmatrix}.
\]

Further, we define the block diagonal matrix \( E \in \mathbb{R}^{d \times d} \) as

\[
E = \sum_{j=1}^{m} E_j = \begin{pmatrix}
\tilde{E}_1 & 0 \\
& \ddots & \\
0 & & \tilde{E}_m \\
\end{pmatrix}.
\]

In analogy to the terminology in [11, Definition 1.1.1], a random field \( \{ X(x) : x \in \mathbb{R}^d \} \) is called operator scaling stable random sheet if for some \( H_1,\ldots,H_m > 0 \) we have

\[
\{ X(c^{E_j} x) : x \in \mathbb{R}^d \} \ f.d. \Rightarrow \{ c^{H_j} X(x) : x \in \mathbb{R}^d \}
\]

for all \( c > 0 \) and \( j = 1,\ldots,m \). Note that, by applying (1.2) iteratively, any operator scaling stable random sheet is also operator scaling for the matrix \( E \) and the exponent \( H = \sum_{j=1}^{m} H_j \) in the sense of (1.1). Further, note that this definition is indeed a generalization of operator scaling random fields, since for \( m = 1, d = d_1 \) and \( E = E_1 = \tilde{E}_1 \), (1.2) coincides with the definition introduced in [4]. Another example of a random field satisfying (1.2) is given by the fractional Brownian sheet, where \( E_j = d_j = 1 \) for \( j = 1,\ldots,m \) in this case. Operator scaling stable random sheets have been proven to be quite flexible in modeling physical phenomena and can be
applied in order to extend the well-known Cahn–Hilliard phase-field model. See [1]
and the references therein for more information.

Random fields satisfying a scaling property such as (1.1) or (1.2) are very popular
in modeling, see [14,22] and the references in [5] for some applications. Most of these
fields are Gaussian. However, Gaussian fields are not always flexible for example in
modeling heavy tail phenomena. For this purpose, \( \alpha \)-stable random fields have been
introduced. See [17] for a good introduction to \( \alpha \)-stable random fields.

Using a moving average and a harmonizable representation, the authors in [4]
defined and analyzed two different classes of symmetric \( \alpha \)-stable random fields sat-
sifying (1.1). Following the outline in [4,5], these two classes were generalized to
random fields satisfying (1.2) in [11]. The fields constructed in [4] have stationary
increments, i.e., they satisfy

\[
\{ X(x + h) - X(h) : x \in \mathbb{R}^d \} \overset{f.d.}{=} \{ X(x) : x \in \mathbb{R}^d \} \quad \text{for all } h \in \mathbb{R}^d.
\]

This property has been proven to be quite useful in studying the sample path properties.
However, the property of stationary increments is no more true for the fields constructed
in [11]. The absence of this property is one of the challenging difficulties we face in
determining results about their sample paths.

Another main tool in studying sample paths of operator scaling stable random sheets
are polar coordinates with respect to the matrices \( E_j \), \( j = 1, \ldots, m \), introduced in
[16] and used in [4,5]. If \( \{ X(x) : x \in \mathbb{R}^d \} \) is an operator scaling symmetric \( \alpha \)-stable
random sheet with \( \alpha = 2 \), using (1.2), one can write the variance of \( X(x), x \in \mathbb{R}^d \), as

\[
\mathbb{E}[X^2(x)] = \tau_E(x)^{2H} \mathbb{E}[X^2(l_E(x))],
\]

where \( H = \sum_{j=1}^m H_j \) and \( \tau_E(x) \) is the radial part of \( x \) with respect to \( E \) and \( l_E(x) \) is
its polar part. Therefore, if the random field has stationary increments in the Gaussian
case information about the behavior of the polar coordinates \( (\tau_{E_j}(x), l_{E_j}(x)) \) contains
information about the sample path regularity. This property also holds in the stable
case \( \alpha \in (0, 2) \). Moreover, this also remains to be true for operator scaling random
sheets which do not have stationary increments but satisfy a slightly weaker property,
see Corollary 3.3 below.

This paper is organized as follows. In Sect. 2, we introduce the main tools we need
for the study in this paper. Section 2.1 is devoted to a spectral decomposition result
from [16]. Section 2.2 is about the change to polar coordinates with respect to scaling
matrices and we establish a relation between the radius \( \tau_E(x) \) and the radii \( \tau_{E_j}(x) \),
\( 1 \leq j \leq m \), in Lemma 2.2 below. In Sect. 3, we present the results in [11] about
the existence of harmonizable and moving average representations of operator scaling
\( \alpha \)-stable random sheets. Here, we will only focus on a harmonizable representation.
Moreover, we prove that these random sheets fulfill a generalized type of modulus of
continuity, which is deduced by showing the applicability of results in [5,6]. Based
on this and generalizing a combination of methods used in [2,4,5,24], in Sect. 4 we
present our results on the Hausdorff dimension and box-counting dimension of the
graph of harmonizable operator scaling stable random sheets.
2 Preliminaries

2.1 Spectral Decomposition

Let $A \in \mathbb{R}^{d \times d}$ be a matrix with $p$ distinct positive real parts of its eigenvalues $0 < a_1 < \cdots < a_p$ for some $p \leq d$. Factor the minimal polynomial of $A$ into $f_1, \ldots, f_p$, where all roots of $f_i$ have real part equal to $a_i$, and define $V_i = \ker \left( f_i(A) \right)$. Then, by [16, Theorem 2.1.14],

$$\mathbb{R}^d = V_1 \oplus \cdots \oplus V_p$$

is a direct sum decomposition, i.e. we can write any $x \in \mathbb{R}^d$ uniquely as

$$x = x_1 + \cdots + x_p$$

for $x_i \in V_i$, $1 \leq i \leq p$. Further, we can choose an inner product on $\mathbb{R}^d$ such that the subspaces $V_1, \ldots, V_p$ are mutually orthogonal. Throughout this paper, for any $x \in \mathbb{R}^d$ we will choose $\|x\| = \langle x, x \rangle^{1/2}$ as the corresponding Euclidean norm. In view of our methods this will entail no loss of generality, since all norms are equivalent.

2.2 Polar Coordinates

We now recall the results about the change to polar coordinates used in [4,5]. As before, let $A \in \mathbb{R}^{d \times d}$ be a matrix with distinct positive real parts of its eigenvalues $0 < a_1 < \cdots < a_p$ for some $p \leq d$. According to [4, Sect. 2] there exists a norm $\| \cdot \|_A$ on $\mathbb{R}^d$ such that for the unit sphere $S_A = \{ x \in \mathbb{R}^d : \|x\|_A = 1 \}$ the mapping

$$\Psi_A : (0, \infty) \times S_A \to \mathbb{R}^d \setminus \{0\}$$

defined by $\Psi_A(r, \theta) = r^A \theta$ is a homeomorphism. To be more precise, the norm $\| \cdot \|_A$ is defined by

$$\|x\|_A = \int_0^1 \|t^A x\| \frac{dt}{t}, \quad x \in \mathbb{R}^d. \tag{2.1}$$

Thus, we can write any $x \in \mathbb{R}^d \setminus \{0\}$ uniquely as

$$x = \tau_A(x)^A l_A(x), \tag{2.2}$$

where $\tau_A(x) > 0$ is called the radial part of $x$ with respect to $A$ and $l_A(x) \in \{ x \in \mathbb{R}^d : \tau_A(x) = 1 \}$ is called the direction. It is clear that $\tau_A(x) \to \infty$ as $\|x\| \to \infty$ and $\tau_A(x) \to 0$ as $\|x\| \to 0$. Further, one can extend $\tau_A(\cdot)$ continuously to $\mathbb{R}^d$ by setting $\tau_A(0) = 0$. Note that, by (2.2), it is straightforward to see that $\tau_A(\cdot)$ satisfies

$$\tau_A(c^A x) = c \cdot \tau_A(x) \quad \text{for all } c > 0.$$ 

Such functions are called $A$-homogeneous.

Let us recall a result about bounds on the growth rate of $\tau_A(\cdot)$ in terms of $a_1, \ldots, a_p$ established in [4, Lemma 2.1].

\[ \text{Springer} \]
Lemma 2.1  Let \( \varepsilon > 0 \) be small enough. Then, there exist constants \( K_1, \ldots, K_4 > 0 \) such that

\[
K_1 \| x \|_1^{\frac{1}{\varepsilon_1} + \varepsilon} \leq \tau_A(x) \leq K_2 \| x \|_p^{\frac{1}{\varepsilon_p} - \varepsilon}
\]

for all \( x \) with \( \tau_A(x) \leq 1 \), and

\[
K_3 \| x \|_p^{\frac{1}{\varepsilon_p} - \varepsilon} \leq \tau_A(x) \leq K_4 \| x \|_1^{\frac{1}{\varepsilon_1} + \varepsilon}
\]

for all \( x \) with \( \tau_A(x) \geq 1 \).

We remark that the bounds on the growth rate of \( \tau_A(\cdot) \) have been improved in [5, Proposition 3.3], but the bounds given in Lemma 2.1 suffice for our purposes.

The following Lemma will be needed in the next section in order to give an upper bound on the modulus of continuity.

Lemma 2.2  Let \( E, \tilde{E}_1, \ldots, \tilde{E}_m \) be as above. Then, there exists a constant \( C \geq 1 \) such that

\[
C^{-1} \sum_{j=1}^{m} \tau_{\tilde{E}_j} (x_j) \leq \tau_E (x) \leq C \sum_{j=1}^{m} \tau_{\tilde{E}_j} (x_j)
\]

for any \( x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} = \mathbb{R}^d \).

Proof  Let \( \mathbb{R}^{d_j} := \{0\} \times \cdots \times \{0\} \times \mathbb{R}^{d_j} \times \{0\} \times \cdots \times \{0\} \subset \mathbb{R}^d, 1 \leq j \leq m, \) be a subspace and note that

\[
\mathbb{R}^d = \mathbb{R}^{d_1} \oplus \cdots \oplus \mathbb{R}^{d_m}
\]

is a direct sum decomposition with respect to \( E \). Throughout, write \( x = (x_1, \ldots, x_m) = \tilde{x}_1 + \cdots + \tilde{x}_m \) with respect to this decomposition. From [15, Lemma 2.2], we have for some \( c \geq 1 \)

\[
\frac{1}{c} \sum_{i=1}^{m} \tau_E (\tilde{x}_i) \leq \tau_E (x) \leq c \sum_{i=1}^{m} \tau_E (\tilde{x}_i).
\]

It remains to prove \( \tau_E (\tilde{x}_i) = \tau_{\tilde{E}_i} (x_i) \) for \( 1 \leq i \leq m \). Without loss of generality assume \( i = 1 \) and for simplicity in this proof let us assume that \( m = 2 \). Thus, for any vector \( x \in \mathbb{R}^d \) let us write \( x = (x_1, x_2) \in \mathbb{R}^{d_1} \times \mathbb{R}^{d_2} \). Note that by definition

\[
(x_1, 0) = \tau_E(x_1, 0)^{E_1} I_E (x_1, 0) = \left( \tau_{E_1}(x_1, 0)^{E_1} I_{E_1} (x_1, 0)_1, \tau_{E_1}(x_1, 0)^{E_2_1} I_{E_2} (x_1, 0)_2 \right)
\]

\[
= \left( \tau_{E_1}(x_1, 0)^{E_1} I_{E_1} (x_1, 0)_1, 0 \right).
\]
where we used the notation $l_E(x) = (l_E(x)_1, l_E(x)_2) \in \mathbb{R}^{d_1} \times \mathbb{R}^{d_2}$. But on the other hand one can write

$$x_1 = \tau_{\tilde{E}_1}(x_1)\tilde{E}_1 l_{\tilde{E}_1}(x_1)$$

yielding that

$$\tau_{\tilde{E}_1}(x_1)\tilde{E}_1 l_{\tilde{E}_1}(x_1) = \tau_E(x_1, 0)\tilde{E}_1 l_E(x_1, 0)_{1}.$$ 

Further noting that

$$l_{\tilde{E}_1}(x_1, 0) = (l_{\tilde{E}_1}(x_1, 0)_1, l_{\tilde{E}_1}(x_1, 0)_2) = (l_E(x_1, 0)_1, 0)$$

and taking into account the definition of the norm $\| \cdot \|_{\tilde{E}_1}$ given in (2.1) we obtain

$$\|l_{\tilde{E}_1}(x_1)\|_{\tilde{E}_1} = 1 = \|l_E(x_1, 0)_1, 0\|_E = \int_0^1 \|t E(l_E(x_1, 0)_1, 0)\| \frac{dt}{t}$$

$$= \int_0^1 \|t \tilde{E}_1 l_E(x_1, 0)_1\| \frac{dt}{t} = \|l_E(x_1, 0)_1\|_{\tilde{E}_1}$$

Thus, by the uniqueness of the representation we have $\tau_{\tilde{E}_1}(x_1) = \tau_E(x_1, 0)$ and $l_{\tilde{E}_1}(x_1) = l_E(x_1, 0)_1$ as desired. This concludes the proof. $\square$

**Corollary 2.3** Let $E, \tilde{E}_1, \ldots, \tilde{E}_m$ be as above. Then, there exists a constant $C \geq 1$ such that

$$C^{-1} \sum_{j=1}^{m} \tau_{\tilde{E}_j}(x_j)^H \leq \tau_E(x)^H$$

for any $H > 0$ and $x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} = \mathbb{R}^d$.

### 3 Harmonizable Operator Scaling Random Sheets

We consider harmonizable operator scaling stable random sheets defined in [11] and present some related results established in [11]. Most of these will also follow from the results derived in [4, 5]. Throughout this paper, for $j = 1, \ldots, m$ assume that the real parts of the eigenvalues of $\tilde{E}_j$ are given by $0 < a_1^j < \cdots < a_{p_j}^j$ for some $p_j \leq d_j$. Let $q_j = \text{trace}(\tilde{E}_j)$. Suppose that $\psi_j : \mathbb{R}^{d_j} \to [0, \infty)$ are continuous $\tilde{E}_j^T$-homogeneous functions, which means according to [4, Definition 2.6] that

$$\psi_j(c \tilde{E}_j^T x) = c \psi_j(x) \quad \text{for all } c > 0.$$ 

Moreover, we assume that $\psi_j(x) \neq 0$ for $x \neq 0$. See [4, 5] for various examples of such functions.
Let $0 < \alpha \leq 2$ and $W_\alpha(d\xi)$ be a complex isotropic symmetric $\alpha$-stable random measure on $\mathbb{R}^d$ with Lebesgue control measure (see [17, Chapter 6.3]).

**Theorem 3.1** For any vector $x \in \mathbb{R}^d$ let $x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} = \mathbb{R}^d$. The random field

$$X_\alpha(x) = \text{Re} \int_{\mathbb{R}^d} \prod_{j=1}^m (e^{i \langle x_j, \xi_j \rangle} - 1) \psi_j(\xi_j)^{-H_j - q_j} W_\alpha(d\xi), \quad x \in \mathbb{R}^d \quad (3.1)$$

exists and is stochastically continuous if and only if $H_j \in (0, a_j^\perp)$ for all $j = 1, \ldots, m$.

**Proof** This result has been proven in detail in [11], but it also follows as an easy consequence of [4, Theorem 4.1]. By the definition of stable integrals (see [17]), $X_\alpha(x)$ exists if and only if

$$\Gamma_\alpha(x) = \int_{\mathbb{R}^d} \prod_{j=1}^m |e^{i \langle x_j, \xi_j \rangle} - 1|^\alpha \psi_j(\xi_j)^{-\alpha H_j - q_j} d\xi < \infty,$$

but this is equivalent to

$$\Gamma_j^{\perp}(x) = \int_{\mathbb{R}^d_j} |e^{i \langle x_j, \xi_j \rangle} - 1|^\alpha \psi_j(\xi_j)^{-\alpha H_j - q_j} d\xi_j < \infty,$$

for all $j = 1, \ldots, m$. Since, in [4, Theorem 4.1], it is shown that $\Gamma_j^{\perp}(x)$ is finite if and only if $H_j \in (0, a_j^\perp)$ the statement follows, see [11] for details. The stochastic continuity can be deduced similarly as a consequence of [4, Theorem 4.1]. \qed

Note that from (3.1) it follows that $X_\alpha(x) = 0$ for all $x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} = \mathbb{R}^d$ such that $x_j = 0$ for at least one $j \in \{1, \ldots, m\}$.

The following result has been established in [11, Corollary 4.2.1]. The proof is carried out as the proof of [4, Corollary 4.2 (a)] via characteristic functions of stable integrals and by noting that $cE_j x = (x_1, \ldots, x_j-1, cE_j x_j, x_{j+1}, \ldots, x_m)$ for all $c > 0$ and $x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} = \mathbb{R}^d$.

**Corollary 3.2** Under the conditions of Theorem 3.1, the random field $\{X_\alpha(x) : x \in \mathbb{R}^d\}$ is operator scaling in the sense of (1.2), that is, for any $c > 0$

$$\{X(cE_j x) : x \in \mathbb{R}^d\} \overset{\text{f.d.}}{=} \{cH_j X(x) : x \in \mathbb{R}^d\}. \quad (3.2)$$

As we shall see below, fractional Brownian sheets fall into the class of random fields given by (3.1). It is known that a fractional Brownian sheet does not have stationary increments. Thus, in general, a random field given by (3.1) does not possess stationary increments. But it satisfies a slightly weaker property, as the following statement shows.
Corollary 3.3 Under the conditions of Theorem 3.1, for any \( h \in \mathbb{R}^{d_j}, \ j = 1, \ldots, m \)
\[
\{X_{\alpha}(x_1, \ldots, x_{j-1}, x_j + h, x_{j+1}, \ldots, x_m) - X_{\alpha}(x_1, \ldots, x_{j-1}, h, x_{j+1}, \ldots, x_m) : x \in \mathbb{R}^d\}
\]
\[
td \{X_{\alpha}(x) : x \in \mathbb{R}^d\},
\]
where we used the notation \( x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \ldots \times \mathbb{R}^{d_m} = \mathbb{R}^d \).

Proof This result has been established in [11, Corollary 4.2.2] and is proven similarly to [4, Corollary 4.2 (b)].

As an easy consequence of the results in this paper, we will derive global Hölder critical exponents of the random fields defined in (3.1). Following [7, Definition 5], \( \beta \in (0, 1) \) is said to be the Hölder critical exponent of the random field \( \{X(x) : x \in \mathbb{R}^d\} \), if there exists a modification \( X^* \) of \( X \) such that for any \( s \in (0, \beta) \) the sample paths of \( X^* \) satisfy almost surely a uniform Hölder condition of order \( s \) on any compact set \( I \subset \mathbb{R}^d \), i.e., there exists a positive and finite random variable \( Z \) such that almost surely

\[
|X^*(x) - X^*(y)| \leq Z\|x - y\|^s \quad \text{for all } x, y \in I,
\]
whereas, for any \( s \in (\beta, 1) \), (3.3) almost surely fails.

Let us now state our main result of this section. Note that under the assumption \( H_j < a_1^j \) and up to considering matrices \( \bar{E}_j = \frac{E_j}{\mu_j} \) instead of \( E_j \) in (1.2), \( 1 \leq j \leq m \), and with the observation that

\[
c_1^j \tau_{\bar{E}_j}(x_j)^H_j \leq \frac{\tau_{\bar{E}_j}(x_j)^H_j}{\mu_j} \leq c_2^j \tau_{\bar{E}_j}(x_j)^H_j, \quad \forall x_j \in \mathbb{R}^{d_j}
\]

for some positive and finite constants \( c_1^j, c_2^j \) as noted in [6, Remark 5.1], without loss of generality we will assume \( H_j = 1 < a_1^j \) in the proof of the following statement. We will make this assumption for notational convenience.

Proposition 3.4 Under the above assumptions and the assumption that \( H_j = 1 \) or, equivalently \( a_1^j > 1 \) for \( j = 1, \ldots, m \) there exists a modification \( X_{\alpha}^* \) of the random field in (3.1) such that for any \( \epsilon > 0 \) and any non-empty compact set \( G_d \subset \mathbb{R}^d \)

\[
\sup_{x, y \in G_d} \frac{|X_{\alpha}^*(x) - X_{\alpha}^*(y)|}{\sum_{j=1}^m \tau_{\bar{E}_j}(x_j - y_j)^H_j \left[ \log \left( 1 + \sum_{j=1}^n \tau_{\bar{E}_j}(x_j - y_j)^{-1} \right) \right]^{\frac{1}{2}}} < \infty \quad a.s.
\]

if \( \alpha = 2 \) and

\[
\sup_{x, y \in G_d} \frac{|X_{\alpha}^*(x) - X_{\alpha}^*(y)|}{\sum_{j=1}^m \tau_{\bar{E}_j}(x_j - y_j)^H_j \left[ \log \left( 1 + \sum_{j=1}^n \tau_{\bar{E}_j}(x_j - y_j)^{-1} \right) \right]^{\frac{1}{2} + \frac{1}{\alpha}}} < \infty \quad a.s.
\]
if \( \alpha \in (0, 2) \), where we used the notation \( x = (x_1, \ldots, x_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} = \mathbb{R}^d \). In particular, for any \( 0 < \gamma < H_j \) and \( x = (x_1, \ldots, x_m) \), \( y = (y_1, \ldots, y_m) \in G_d \) one can find a positive and finite constant \( C \) such that

\[
|X^*_\alpha(x) - X^*_\alpha(y)| \leq C \sum_{j=1}^m \tau_{E_j}(x_j - y_j)^\gamma
\]

holds almost surely.

**Proof** Let us first assume that \( \alpha = 2 \). In the following let \( \|\cdot\|_p \) denote the \( p \)-norm for \( p \geq 1 \), \( c \) an unspecified positive constant, \( G_d \subset \mathbb{R}^d \) an arbitrary compact set, \( r > 0 \) and \( B_E(r) = \{x \in \mathbb{R}^d : \tau_E(x) \leq r\} \). Moreover, by

\[
d_X(x, y) = \mathbb{E}[|X_2(x) - X_2(y)|^2]^{1/2}, \quad x, y \in \mathbb{R}^d,
\]

we denote the canonical metric associated to \( X_2 \). We first show for \( x, y \in G_d \) that

\[
d_X(x, y) \leq c \tau_E(x - y).
\]

By the equivalence of norms one can find a constant \( c \) such that

\[
\frac{1}{c} \sum_{i=1}^m |u_i|^2 \leq \left( \sum_{i=1}^m |u_i| \right)^2 \leq c \sum_{i=1}^m |u_i|^2
\]

for any \( u \in \mathbb{R}^m \). Further let us remark that by definition the variance of the centered Gaussian random variable \( X_2(x) \) in (3.1) is given by

\[
\Gamma^2(x) = \mathbb{E}[X_2(x)^2] = c \int_{\mathbb{R}^d} \prod_{j=1}^m |e^{i(x_j, \xi_j)} - 1|^2 \psi_j(\xi_j)^{-2-q_j} d\xi.
\]

Note that for all \( 1 \leq j \leq m \) and \( x = (x_1, \ldots, x_m) \in G_d \) one can find a constant \( 0 < M(x) < \infty \) such that

\[
\Gamma^2(x_1, \ldots, x_{j-1}, \theta, x_{j+1}, \ldots, x_n) \leq M(x) \leq \max_{x \in G_d} M(x) =: M \in (0, \infty),
\]

where \( \theta \in \mathbb{R}^{d_j} \) with \( \tau_{E_j}(\theta) = 1 \). Using all this and the elementary inequality

\[
|X_2(x) - X_2(y)| \leq \sum_{i=1}^m |X_2(x_1, \ldots, x_{i-1}, x_i, y_{i+1}, \ldots, y_m) - X_2(x_1, \ldots, x_{i-1}, y_i, y_{i+1}, \ldots, y_m)|
\]
with the convention that
\[ X_2(x_1, \ldots, x_{i-1}, y_i, y_{i+1}, \ldots, y_m) = X_2(y) \]
for \( i = 1 \) and
\[ X_2(x_1, \ldots, x_{i-1}, x_i, y_{i+1}, \ldots, y_m) = X_2(x) \]
for \( i = m \) we get for all \( x = (x_1, \ldots, x_m) \) and \( y = (y_1, \ldots, y_m) \in G_d \)
\[
\mathbb{E}[(|X_2(x) - X_2(y)|^2)] 
\leq c \mathbb{E} \left[ \sum_{i=1}^{m} |X_2(x_1, \ldots, x_{i-1}, x_i, y_{i+1}, \ldots, y_m) - X_2(x_1, \ldots, x_{i-1}, y_i, y_{i+1}, \ldots, y_m)|^2 \right] 
\leq c \mathbb{E} \left[ \sum_{i=1}^{m} |X_2(x_1, \ldots, x_{i-1}, x_i, y_{i+1}, \ldots, y_m) - X_2(x_1, \ldots, x_{i-1}, y_i, y_{i+1}, \ldots, y_m)|^2 \right] 
= c \mathbb{E} \left[ \left( \sum_{i=1}^{m} |X_2(x_1, \ldots, x_{i-1}, x_i - y_i, y_{i+1}, \ldots, y_m)| \right)^2 \right],
\]
where we used Corollary 3.3 in the equality and the equivalence of norms in the last inequality. Using the operator scaling property and the generalized polar coordinates for \( x_i - y_i \) we can further get an upper estimate of the last expression by
\[
c \sum_{i=1}^{m} \tau_{\tilde{E}_i}^2(x_i - y_i)^2 \mathbb{E} \left[ |X_2(x_1, \ldots, x_{i-1}, l_{\tilde{E}_i}(x_i - y_i), y_{i+1}, \ldots, y_m)|^2 \right] 
\leq c M \sum_{i=1}^{m} \tau_{\tilde{E}_i}^2(x_i - y_i)^2 \leq c M \tau_E^2 (x - y)^2,
\]
where we used Corollary 2.3 with \( H = 2 \) in the last inequality, which proves \( (3.5) \).

Now define an auxiliary Gaussian random field \( Y = \{Y(t, s) : t \in G_d, s \in B_E(r)\} \) by
\[
Y(t, s) = X_2(t + s) - X_2(t), \quad t \in G_d, s \in B_E(r),
\]
where \( r > 0 \) is such that \( B_E(r) \subset G_d \). Denote by \( D \) the diameter of \( G_d \times B_E(r) \) in the metric \( d_Y \) associated with \( Y \). Then, using \( (3.5) \) it is easy to see that \( D \leq cr \) for some positive constant \( c \). Using the latter inequality, by the arguments made in the proof of [15, Theorem 4.2] if \( N(\varepsilon) \) denotes the smallest number of open \( d_Y \)-balls of radius \( \varepsilon > 0 \) needed to cover \( G_d \times B_E(r) \) we obtain that
\[
\int_0^D \sqrt{\log N(\varepsilon)} d\varepsilon \leq c r \sqrt{\log(1 + r^{-1})}.
\]
Then, it follows from [21, Lemma 2.1] that for all $u \geq 2cr\sqrt{\log(1+r^{-1})}$

$$
P\left( \sup_{(t,s)\in G_d \times B_E(r)} |X_2(t+s) - X_2(t)| \geq u \right) \leq \exp\left(-\frac{u^2}{4D^2}\right).
$$

Therefore, by a standard Borel-Cantelli argument we conclude

$$
\sup_{x,y \in G_d \times B_E(r)} \frac{|X_2^*(x) - X_2^*(y)|}{\tau_E(x-y)\sqrt{\log(1+\tau_E(x-y)^{-1})}} < \infty \text{ a.s. (3.6)}
$$

for a continuous modification $X_2^*$ of $X_2$, which by Lemma 2.2 is equivalent to

$$
\sup_{x,y \in G_d \times B_E(r)} \frac{|X_2^*(x) - X_2^*(y)|}{\tau_E(x-y)\sqrt{\log(1+\tau_E(x-y)^{-1})}} < \infty \text{ a.s.}
$$

Let us now assume that $\alpha \in (0, 2)$. In this case, the proof is a slight modification and extension of the proof of [6, Proposition 5.1] and the idea is to check the assumptions (i), (ii) and (iii) of Proposition 4.3 of the latter reference. Throughout this proof, we let $c$ be a universal unspecified positive and finite constant and in the following let

$$
f_{\alpha}(u, \xi) = \prod_{j=1}^{m} (e^{i(u_j, \xi_j)} - 1)\psi_{\alpha}(\xi)
$$

with

$$
\psi_{\alpha}(\xi) = \prod_{j=1}^{m} \tau_E(\xi_j)^{-1-\frac{q_j}{\alpha}}.
$$

As in [6, Example 5.1] one checks that for all $\xi \in \mathbb{R}^d$, $\xi_j \neq 0$,

$$
\psi_{\alpha}(\xi) \leq c \prod_{j=1}^{m} \tau_E(\xi_j)^{-1-\frac{q_j}{\alpha}} \quad (3.7)
$$

and, in particular there exist constants $A_j > 0$, $1 \leq j \leq m$, such that (3.7) holds for all $\|\xi_j\| > A_j$. For $\zeta > 0$ chosen arbitrarily small we consider the function $\tilde{\mu}$ on $\mathbb{R}^d$ given by $\tilde{\mu}(\xi) = \prod_{j=1}^{m} \tilde{\mu}_j(\xi_j)$ with

$$
\tilde{\mu}_j(\xi_j) = \left(\|\xi_j\| + 1\right)^{\alpha} \prod_{\|\xi_j\| \geq A_j} + \tau_E(\xi_j)^{-q_j} |\log \tau_E(\xi_j)|^{-1-\zeta} \prod_{\|\xi_j\| > A_j}.
$$
We observe that \( \tilde{\mu} \) is positive on \( \mathbb{R}^d \setminus \{0\} \) and, similarly to the calculations made in the proof of [6, Proposition 5.1], we obtain that

\[
\int_{\mathbb{R}^d_{j}} \tilde{\mu}_j(\xi_j)d\xi_j = c \in (0, \infty), \quad \forall 1 \leq j \leq m.
\]

Define \( \mu_j = \frac{\tilde{\mu}_j}{c} \). Moreover, note that

\[
\int_{\mathbb{R}^d} \tilde{\mu}(\xi)d\xi = c \in (0, \infty).
\]

Hence, \( \mu = \frac{\tilde{\mu}}{c} \) is well defined and now, as in the proof of [6, Proposition 5.1], we are going to check the assumptions (i), (ii) and (iii) of [6, Proposition 4.3] for

\[
V_1(u) = f_{\alpha}(u, \Xi)\mu(\Xi)^{-\frac{1}{\alpha}},
\]

where \( u \in \mathbb{R}^d \) and \( \Xi \) is assumed to be a random vector on \( \mathbb{R}^d \) with density \( \mu \).

We choose a constant \( c \in (0, \infty) \) such that

\[
\left| \prod_{j=1}^{m} (e^{i(x_j \cdot \xi_j)} - 1) - \prod_{j=1}^{m} (e^{i(y_j \cdot \xi_j)} - 1) \right| \leq \prod_{j=1}^{m} c \| \tau_E(x - y) \bar{E}_j \xi_j \| \bar{E}_j.
\]

Note that this is possible. Then, it follows

\[
|V_1(x) - V_1(y)| \leq |\psi_{\alpha}(\xi)| \prod_{j=1}^{m} \min \left( c \| \rho(x, y) \bar{E}_j \xi_j \| \bar{E}_j, 1 \right)
\]

for the quasi-metric \( \rho \) on \( \mathbb{R}^d \) defined by

\[
\rho(x, y) = \tau_E(x - y), \quad \forall x, y \in \mathbb{R}^d.
\]

Hence, we have

\[
|V_1(x) - V_1(y)| \leq g \left( \rho(x, y), \Xi \right)
\]

with \( g \) defined by

\[
g(h, \xi) = |\psi_{\alpha}(\xi)| \prod_{j=1}^{m} \min \left( c \| h \bar{E}_j \xi_j \| \bar{E}_j, 1 \right),
\]

so that we precisely recover assumption (i) in [6, Proposition 4.3] for the random field \( \mathcal{G} = (g(h, \xi))_{h \in [0, \infty)} \). Moreover, assumption (ii) immediately follows as in the proof of [6, Proposition 5.1] from the definition of the norms \( \| \cdot \| \bar{E}_j \) and by noting that the
product of monotonic functions again is monotonic. It remains to prove assumption (iii) in [6, Proposition 4.3]. To this end we write

\[ I(h) := \mathbb{E}[\mathcal{G}^2(h)] = \int_{\mathbb{R}^d} g(h, \xi)^2 \mu(\xi)^{1 - \frac{2}{a}} d\xi \]

\[ = \prod_{j=1}^m \int_{\mathbb{R}^{d_j}} \min \left( c \| h \tilde{E}_j \xi_j \| \tilde{E}_j^T, 1 \right)^2 \psi_j(\xi_j)^{-2 - \frac{2q_j}{a}} \mu_j(\xi_j)^{1 - \frac{2}{a}} d\xi_j. \]

Using equality (3.7) similarly as shown in the calculations made in the proof of [6, Proposition 5.1] we obtain that

\[ \int_{\mathbb{R}^{d_j}} \min \left( c \| h \tilde{E}_j \xi_j \| \tilde{E}_j^T, 1 \right)^2 \psi_j(\xi_j)^{-2 - \frac{2q_j}{a}} \mu_j(\xi_j)^{1 - \frac{2}{a}} d\xi_j \leq c h^2 | \log(h) |^{2(1+\zeta)(\frac{1}{a} - \frac{1}{2})} \]

which yields that

\[ I(h) = \prod_{j=1}^m \int_{\mathbb{R}^{d_j}} \min \left( c \| h \tilde{E}_j \xi_j \| \tilde{E}_j^T, 1 \right)^2 \psi_j(\xi_j)^{-2 - \frac{2q_j}{a}} \mu_j(\xi_j)^{1 - \frac{2}{a}} d\xi_j \]

\[ \leq c h^{2m} | \log(h) |^{2m(1+\zeta)(\frac{1}{a} - \frac{1}{2})}, \]

so that assumption (iii) in [6, Proposition 4.3] with \( pm \) instead of \( p \) is fulfilled. Following the lines of the proof of [6, Proposition 5.1], we obtain that there exists a modification \( X^*_\alpha \) of \( X_\alpha \) such that

\[ \sup_{x, y \in G_d, x \neq y} \frac{|X^*_\alpha(x) - X^*_\alpha(y)|}{\tau_E(x - y) \left[ \log \left( 1 + \tau_E(x - y)^{-1} \right) \right]^{\frac{1}{1 + \frac{1}{a}}}} < \infty \ a.s. \]

for any \( \varepsilon > 0 \) and any non-empty compact set \( G_d \subset \mathbb{R}^d \), which by Lemma 2.2 is equivalent to

\[ \sup_{x, y \in G_d, x \neq y} \frac{|X^*_\alpha(x) - X^*_\alpha(y)|}{\sum_{j=1}^m \tau_{\tilde{E}_j}(x_j - y_j) \left[ \log \left( 1 + \sum_{j=1}^m \tau_{\tilde{E}_j}(x_j - y_j)^{-1} \right) \right]^{\frac{1}{1 + \frac{1}{a}}}} < \infty \ a.s. \]

This completes the proof. \( \Box \)

**Corollary 3.5** Under the assumptions of Theorem 3.1, there exist a positive and finite random variable \( Z \) and a continuous modification of \( X_\alpha \) such that for any \( s \in (0, \min_{1 \leq j \leq m} \frac{H_j}{a p_j}) \) the uniform Hölder condition (3.3) holds almost surely.

We remark that Corollary 3.5 is not a statement about critical Hölder exponents. However, as a consequence of Theorem 4.1 below, we will see that any continuous version of \( X_\alpha \) admits \( \min_{1 \leq j \leq m} \frac{H_j}{a p_j} \) as the critical exponent.
4 Hausdorff Dimension

We now state our main result on the Hausdorff and box-counting dimension of the graph of $X_\alpha$ defined in (3.1). In the following, for a set $B \subset \mathbb{R}^d$ we denote by $\dim_B B$, $\dim B$ and $\dim_H B$ its lower, upper box-counting and Hausdorff dimension, respectively. We refer to [9] for a definition of these objects.

**Theorem 4.1** Suppose that the conditions of Theorem 3.1 hold. Then, for any continuous version of $X_\alpha$, almost surely

$$\dim_H G X_\alpha([0, 1]^d) = \dim_B G X_\alpha([0, 1]^d) = d + 1 - \min_{1 \leq j \leq m} \frac{H_j}{a_{p_j}}, \quad (4.1)$$

where

$$G X_\alpha([0, 1]^d) = \{(x, X_\alpha(x)) : x \in [0, 1]^d\}$$

is the graph of $X_\alpha$ over $[0, 1]^d$.

**Proof** Let us choose a continuous version of $X_\alpha$ by Corollary 3.5. From Corollary 3.5, for any $0 < s < \min_{1 \leq j \leq m} \frac{H_j}{a_{p_j}}$, the sample paths of $X_\alpha$ satisfy almost surely a uniform Hölder condition of order $s$ on $[0, 1]^d$. Thus, by a $d$-dimensional version of [9, Corollary 11.2] we have

$$\dim_H G X_\alpha([0, 1]^d) \leq \dim_B G X_\alpha([0, 1]^d) \leq d + 1 - s, \quad a.s.$$ 

Letting $s \uparrow \min_{1 \leq j \leq m} \frac{H_j}{a_{p_j}}$ along rational numbers yields the upper bound in (4.1).

It remains to prove the lower bound in (4.1). Since the inequality

$$\dim_B B \geq \dim_H B$$

holds for every $B \subset \mathbb{R}^d$ (see [9, Chapter 3.1]), it suffices to show

$$\dim_H G X_\alpha([0, 1]^d) \geq d + 1 - \min_{1 \leq j \leq m} \frac{H_j}{a_{p_j}}, \quad a.s.$$ 

Further, note that, since $Q = [\frac{1}{2}, 1]^d \subset [0, 1]^d$, we have

$$\dim_H G X_\alpha([0, 1]^d) \geq \dim_H G X_\alpha(Q)$$

by monotonicity of the Hausdorff dimension. Thus, it is even enough to show that

$$\dim_H G X_\alpha(Q) \geq d + 1 - \min_{1 \leq j \leq m} \frac{H_j}{a_{p_j}}, \quad a.s. \quad (4.2)$$
We will show this by combining the methods used in [2,4,5]. From now on, without loss of generality, we will assume that

$$\min_{1 \leq j \leq m} \frac{H_j}{\alpha_{p_j}} = \frac{H_1}{\alpha_{p_1}}.$$  

Let $\gamma > 1$. Following the argument in [4, Theorem 5.6], in view of the Frostman criterion [9, Theorem 4.13 (a)], it suffices to show that

$$I_{\gamma} := \int_{Q \times Q} \mathbb{E}\left[ (\|x - y\|^2 + |X_\alpha(x) - X_\alpha(y)|^2)^{-\frac{\gamma}{2}} \right] dx dy < \infty$$

in order to obtain $\dim_H G_{X_\alpha}(Q) \geq \gamma$ almost surely.

Using the characteristic function of the symmetric $\alpha$-stable random field $X_\alpha$, as in the proof of [5, Proposition 5.7], it can be shown that there is a constant $C_1 > 0$ such that

$$I_{\gamma} \leq C_1 \int_{Q \times Q} \|x - y\|^{1 - \gamma} \sigma^{-1}(x, y) dx dy,$$

where

$$\sigma(x, y) = \|X_\alpha(x) - X_\alpha(y)\|_\alpha.$$

Combining this with Theorem 4.2 below we get

$$I_{\gamma} \leq \tilde{C}_1 \int_{Q \times Q_1} \|x_1 - y_1\|^{1 - \gamma} \tau_{\tilde{E}_1}(x_1 - y_1)^{-H_1} dx_1 dy_1,$$

for some $\tilde{C}_1 > 0$ and $Q_1 = [\frac{1}{2}, 1)^{d_1}$. With this inequality the assertion readily follows from the proof of [4, Theorem 5.6].

The following Theorem is crucial for proving Theorem 4.1 and its proof is based on [23, Theorem 1]. See also [24–26]. Let us remark that a similar method of the following proof has been applied in [24, Theorem 3.4] for certain $\alpha$-stable random fields if $1 \leq \alpha \leq 2$. In the following, we are able to extend this method for $0 < \alpha < 1$ and, in particular this shows that the statement of [24, Theorem 3.5] can be formulated for $0 < \alpha < 1$ as well.

**Theorem 4.2** There exists a constant $C_4 > 0$, depending on $H_1, \ldots, H_m, q_1, \ldots, q_m$ and $d$ only, such that for all $x = (x_1, \ldots, x_m), y = (y_1, \ldots, y_m) \in [\frac{1}{2}, 1)^{d_1} \times \cdots \times [\frac{1}{2}, 1)^{d_m}$ we have

$$\sigma(x, y) \geq C_4 \cdot \tau_{\tilde{E}_1}(x_1 - y_1)^{H_1},$$

where $\tau_{\tilde{E}_1}(\cdot)$ is the radial part with respect to $\tilde{E}_1$.  

\[ Springer \]
Proof Throughout this proof, we fix $x = (x_1, \ldots , x_m), y = (y_1, \ldots , y_m) \in \left[ \frac{1}{2}, 1 \right)^{d_1} \times \cdots \times \left[ \frac{1}{2}, 1 \right)^{d_m}$. We will show that

$$\sigma(x, y) \geq CrH_{l}$$

(4.3)

for some constant $C > 0$ independent of $x$ and $y$ and $r = \tau_{\tilde{E}_{1}}(x_1 - y_1)$. Without loss of generality we will assume that $r > 0$, since for $r = 0$ (4.3) always holds. By definition, we have

$$\sigma^{\alpha}(x, y) = \int_{\mathbb{R}^{d}} | \prod_{j=1}^{m} (e^{i(x_j, \xi_j)} - 1) - \prod_{j=1}^{m} (e^{i(y_j, \xi_j)} - 1) |^{\alpha} \prod_{j=1}^{m} |\psi_{j}(\xi_j)|^{-\alpha H_{j} - a_{j}} d\xi.$$  

(4.4)

Now, for every $j = 1, \ldots , m$ we consider a so-called bump function $\delta_{j} \in C^{\infty}(\mathbb{R}^{d+j})$ with values in $[0, 1]$ such that $\delta_{j}(0) = 1$ and $\delta_{j}$ vanishes outside the open ball

$$B(K_{j}, 0) = \{ z \in \mathbb{R}^{d_{j}} : \tau_{\tilde{E}_{j}}(z) < K_{j} \}$$

for

$$K_{j} = \min \left\{ 1, \frac{K_{j}^{1}}{K_{2}} \left( \sqrt{d_{1}} \frac{1}{2} \right)_{a_{1}}^{1-a_{1}+2\varepsilon}, \frac{K_{j}^{2}}{K_{4}} \left( \sqrt{d_{1}} \frac{1}{2} \right)_{a_{1}}^{1-a_{1}-2\varepsilon}, K_{j}^{3} \left( \sqrt{d_{1}} \frac{1}{2} \right)_{a_{1}+\varepsilon}, K_{3}^{4} \left( \sqrt{d_{1}} \frac{1}{2} \right)_{a_{1}+\varepsilon}, K_{3}^{3} \left( \sqrt{d_{1}} \frac{1}{2} \right)_{a_{1}^{2}}^{a_{1}^{2} - \varepsilon} \right\},$$

where $\varepsilon > 0$ is some (sufficiently) small number and $K_{1}^{1}, \ldots , K_{4}^{j}$ are the suitable constants derived from Lemma 2.1 corresponding to the matrix $\tilde{E}_{j}$. The choice of the constant $K_{j} > 0$ will be clear later in this proof. Let $\hat{\delta}_{j}$ be the Fourier transform of $\delta_{j}$. It can be verified that $\hat{\delta}_{j} \in C^{\infty}(\mathbb{R}^{d+j})$ as well and that $\hat{\delta}_{j}(\lambda_{j})$ decays rapidly as $\| \lambda_{j} \| \to \infty$. By the Fourier inversion formula, we have

$$\delta_{j}(s_{j}) = \frac{1}{(2\pi)^{d_{j}}} \int_{\mathbb{R}^{d_{j}}} e^{-i(s_{j}, \lambda_{j})} \hat{\delta}_{j}(\lambda_{j}) d\lambda_{j}$$

(4.5)

for all $s_{j} \in \mathbb{R}^{d_{j}}$. Let $\delta_{1}^{*}(s_{1}) = \frac{1}{r_{1}^{\alpha}} \delta_{1}(r_{1}^{\frac{1}{2}} \tilde{E}_{1} s_{1})$. Then, by a change of variables in (4.5), for all $s_{1} \in \mathbb{R}^{d_{1}}$ we obtain

$$\delta_{1}^{*}(s_{1}) = \frac{1}{(2\pi)^{d_{1}}} \int_{\mathbb{R}^{d_{1}}} e^{-i(s_{1}, \lambda_{1})} \hat{\delta}_{1}(r_{1}^{\frac{1}{2}} \tilde{E}_{1} \lambda_{1}) d\lambda_{1}.$$  

(4.6)

Using Lemma 2.1 and the fact that $\tau_{\tilde{E}_{1}}(\cdot)$ is $\tilde{E}_{1}$-homogeneous, it is straightforward to see that $\tau_{\tilde{E}_{1}}(x_{1}) \geq K_{1}, \tau_{\tilde{E}_{1}}(\frac{1}{r_{1}} \tilde{E}_{1} (x_{1} - y_{1})) \geq K_{1}$ and $\tau_{\tilde{E}_{1}}(\frac{1}{r_{1}} \tilde{E}_{1} x_{1}) \geq K_{1}$ for
\( r = \tau_{E_1} (x_1 - y_1) > 0 \). Therefore, we have \( \delta_1^r (x_1) = 0, \delta_1^r (x_1 - y_1) = 0 \) and \( \delta_j (x_j) = 0 \) for all \( j = 2, \ldots, m \). Hence, combining this with (4.5) and (4.6) it follows that

\[
I := \int_{\mathbb{R}^d} \left( \prod_{j=1}^m (e^{i(x_j, \lambda_j)} - 1) - \prod_{j=1}^m (e^{i(y_j, \lambda_j)} - 1) \right)
\cdot e^{-i(x_1, \lambda_1)} \delta_1^r (r E_1^{T}) \prod_{j=2}^m \delta_j (\lambda_j) d\lambda
\]

\[
= (2\pi)^d \left( \delta_1^r (0) - \delta_1^r (x_1) \right) \prod_{j=2}^m \left( \delta_j (0) - \delta_j (x_j) \right)
\]

\[
- (2\pi)^d \left( \delta_1^r (x_1 - y_1) - \delta_1^r (x_1) \right) \prod_{j=2}^m \left( \delta_j (x_j - y_j) - \delta_j (x_j) \right)
\]

\[
= (2\pi)^d \frac{1}{r_1 q_1}. \tag{4.7}
\]

For every \( \alpha \in (0, 2) \) we can choose \( k \in \mathbb{N} \) such that \( k\alpha \geq 1 \) and let \( \beta' > 1 \) be the constant such that \( \frac{1}{k\alpha} + \frac{1}{\beta'} = 1 \). We first show that

\[
\left( \int_{\mathbb{R}^d} \prod_{j=1}^m (e^{i(x_j, \lambda_j)} - 1) - \prod_{j=1}^m (e^{i(y_j, \lambda_j)} - 1) \right)^{k\alpha} \prod_{j=1}^m |\psi_j (\lambda_j)|^{-\alpha H_j - q_j} d\lambda \frac{1}{k\alpha}
\]

\[
\leq 2^{k\alpha (m+1)} \sigma (x, y) \frac{1}{r_1}. \tag{4.8}
\]

For \( \lambda = (\lambda_1, \ldots, \lambda_m) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_m} \), let

\[
z(\lambda) = \prod_{j=1}^m (e^{i(x_j, \lambda_j)} - 1) - \prod_{j=1}^m (e^{i(y_j, \lambda_j)} - 1)
\]

and note that, since \( |e^{it} - 1|^2 = 2 - 2 \cos t \leq 4 \) for all \( t \in \mathbb{R} \), it follows that

\[
|z(\lambda)| \leq \prod_{j=1}^m |e^{i(x_j, \lambda_j)} - 1| + \prod_{j=1}^m |e^{i(y_j, \lambda_j)} - 1| \leq 2^{m+1}.
\]

From this, we obtain

\[
\left( \int_{\mathbb{R}^d} |z(\lambda)|^{k\alpha} \prod_{j=1}^m |\psi_j (\lambda_j)|^{-\alpha H_j - q_j} d\lambda \right)^{1/k\alpha}
\]

\[
= \left( \int_{\{\lambda \in \mathbb{R}^{d_1}, |z(\lambda)| \leq 1\}} |z(\lambda)|^{k\alpha} \prod_{j=1}^m |\psi_j (\lambda_j)|^{-\alpha H_j - q_j} d\lambda \right)^{1/k\alpha}
\]

\( \Box \) Springer
Remark 4.4

Let \( \psi \) where \( \psi(\xi_j) = |\xi_j| \) for all \( \xi_j \in \mathbb{R} \). Clearly, \( \psi \) is a homogeneous function and satisfies \( \psi_j(\xi_j) \neq 0 \) for all \( \xi_j \neq 0 \). Thus, by Theorem 3.1, we can define

\[
X_2(x) = \text{Re} \int_{\mathbb{R}^d} \prod_{j=1}^{d} (e^{i x_j \xi_j} - 1)|\xi_j|^{-H_j - \frac{d}{2} H_j} W_2(d\xi), \quad x = (x_1, \ldots, x_d) \in \mathbb{R}^d,
\]

Now, using (4.8), by Hölder’s inequality and (4.4) we have

\[
I \leq \left( \int_{\mathbb{R}^d} \left| \prod_{j=1}^{m} \left( e^{i(x_j,\lambda_j)} - 1 \right) \prod_{j=1}^{m} \left( e^{i(y_j,\lambda_j)} - 1 \right) \right|^{k\alpha} \right)^{1/k\alpha} \cdot \left( \int_{\mathbb{R}^d} \left| \delta_1(r \tilde{E}^T \lambda_1) \prod_{j=2}^{m} \delta_j(\lambda_j) \right|^{\beta'} \right)^{1/\beta'}
\leq 2^{k\alpha(m+1)} \sigma (x, y)^{\frac{1}{2}} \cdot r^{-H_1 - \frac{d}{2}} \left( \int_{\mathbb{R}^d} \left| \delta_1(r \tilde{E}^T \lambda_1) \prod_{j=2}^{m} \delta_j(\lambda_j) \right|^{\beta'} \right)^{1/\beta'}
\leq \tilde{C} \cdot \left( \sigma (x, y) \cdot r^{-H_1 - q_1} \right)^{\frac{1}{2}},
\]

where \( \tilde{C} > 0 \) is a constant, which only depends on \( H_1, \ldots, H_m, q_1, \ldots, q_m, k, \alpha, d \) and \( \delta \). It is clear that (4.3) follows from (4.7) and (4.9). This finishes the proof of the Theorem. \( \square \)

As an immediate consequence of Theorem 4.1, we obtain the following.

**Corollary 4.3** Let the assumptions of Theorem 3.1 hold. Then any continuous version of \( X_\alpha \) admits \( \min_{1 \leq j \leq m} \frac{H_j}{d\beta_j} \) as the Hölder critical exponent.

**Remark 4.4** Let \( \alpha = 2, d_j = \tilde{E}_j = 1 \) for all \( j = 1, \ldots, m \) and consider the function \( \psi(\xi_j) = |\xi_j| \) for all \( \xi_j \in \mathbb{R} \). Clearly, \( \psi \) is a homogeneous function and satisfies \( \psi_j(\xi_j) \neq 0 \) for all \( \xi_j \neq 0 \). Thus, by Theorem 3.1, we can define

\[
X_2(x) = \text{Re} \int_{\mathbb{R}^d} \prod_{j=1}^{d} (e^{i x_j \xi_j} - 1)|\xi_j|^{-H_j - \frac{d}{2} H_j} W_2(d\xi), \quad x = (x_1, \ldots, x_d) \in \mathbb{R}^d,
\]
for all $0 < H_j < 1$, $j = 1, \ldots, d$ and the statement of Theorem 4.1 becomes

$$\dim_{\mathcal{H}} G_{X_2}([0, 1]^d) = \dim_{\mathcal{B}} G_{X_2}([0, 1]^d) = d + 1 - \min_{1 \leq j \leq d} H_j, \ a.s.$$ 

Further, up to a multiplicative constant, the random field $X_2$ is a fractional Brownian sheet with Hurst indices $H_1, \ldots, H_d$ (see [10]). Thus, Theorem 4.1 can be seen as a generalization of [2, Theorem 1.3]. Further, as noted above, for $m = 1, d = d_1$ and $E = E_1 = \tilde{E}_1$ the random field $X_\alpha$ given by (3.1) coincides with the random field in [4, Theorem 4.1] and the statement of Theorem 4.1 becomes

$$\dim_{\mathcal{H}} G_{X_\alpha}([0, 1]^d) = \dim_{\mathcal{B}} G_{X_\alpha}([0, 1]^d) = d + 1 - \frac{H_1}{a_p^1}, \ a.s.$$ 

which is the statement of [4, Theorem 5.6] for $\alpha = 2$ and [5, Proposition 5.7] for $\alpha \in (0, 2)$. We finally remark that Theorem 4.1 can be proven similarly, if we replace $[0, 1]^d$ in (4.1) by any other compact cube of $\mathbb{R}^d$.

We finally remark that the Hausdorff dimension only depends on solely one index $\min_{1 \leq j \leq m} \frac{H_j}{a_p^j}$, whereas in higher space dimensions all indices are relevant and the corresponding results in more general dimensions can be found in [18]. See also [19,20] for related results.
