Abstract—Coded Caching is a promising solution to reduce the peak traffic in broadcast networks by prefetching the popular content close to end users and using coded transmissions. One of the chief issues of most coded caching schemes in literature is the issue of large subpacketization, i.e., they require each file to be divided into a large number of subfiles. In this work, we present a coded caching scheme using line graphs of bipartite graphs in conjunction with projective geometries over finite fields. The presented scheme achieves a rate $\Theta(\log_q K)$ ($K$ being the number of users, $q$ is some prime power) with subexponential subpacketization $q^{O((\log_q K)^2)}$ when cached fraction is upper bounded by a constant $\frac{\gamma}{\alpha}$ for some positive integer $\alpha$). Compared to earlier schemes, the presented scheme has a lower subpacketization (albeit possessing a higher rate). We also present a new subpacketization dependent lower bound on the rate for caching schemes in which each subfile is cached in the same number of users. Compared to the previously known bounds, this bound seems to perform better for a range of parameters of the caching system.

I. INTRODUCTION

The key performance challenges that next generation wireless networks (5G) face are low latency, high throughput and energy efficiency [1]. Content delivery networks have been estimated to carry 72% of the global internet traffic by 2022 [2]. Coded caching was proposed recently in a landmark paper by Maddah-Ali and Niesen [3] and has emerged as an important tool to address major challenges of future communication networks. Since its inception coded caching has proved as an efficient tool to trade-off expensive bandwidth communication networks. Since then several new coded caching schemes with lower subpacketization have been constructed at the cost of increase in rate, or cache requirement, or the number of users [5]–[8]. Among these, an important construction was reported in [6], via a combinatorial object that the authors defined, known as Placement Delivery Arrays (PDAs). The PDA constructed in [6] achieved a global caching gain of $\frac{K}{\log_q K}$ (one less than that of [3]), while improving the subpacketization by an exponential factor compared to [3]. However, in this construction, as well as in most others in literature, the subpacketization required for the caching schemes continues to be exponential in $K$ (for some positive integer $r$) to the best of our knowledge.

Recently, a line graph based approach to coded caching was introduced in [9]. Using this framework, a construction for a caching scheme was given via a projective geometry over a finite field. The scheme presented in [9] achieves a constant rate with subpacketization subexponential in $K$ $\left( F = q^{O(\log_q K^2)} \right)$ for some prime power $q$). However the drawback of this scheme is that the uncached fraction of each file has to be large $\left(1 - \frac{\gamma F}{K}\right) = \Theta\left(\frac{1}{\sqrt{K}}\right)$. We remedy this drawback (to some extent) in this work.

The contributions and organization of this paper are as follows. In Section I, we review the line graph based coded caching scheme proposed in [9], while refining it slightly for our purposes. In Section II, we propose a new lower bound for the optimal rate $R^*$ given parameters $K,F$, and $\gamma$, for the caching schemes in which each subfile is cached in the same number of users, which is a property satisfied by all known centralized caching designs in literature (to the best of our knowledge). Using some numerical examples, we see that this lower bound performs better (for a range of parameters) compared to the previously known bounds in [4], [7]. In Section IV, we present a new coded caching scheme of each client is populated with some popular files of same size (divided into user/network nodes.

In [3], the setup consists of a single server with $N$ equipopular files of same size (divided into $F$ subfiles each of the same size, where $F$ is known as the subpacketization parameter), and $K$ users/clients each having a local memory called cache that can store $MF$ subfiles. The centralized coded caching scheme of [3] works in two phases. In the caching phase (which occurs during off peak times) the cache of each client is populated with some $\frac{\gamma F}{K}$ fraction of each file in the server. In the delivery phase (which happens during peak traffic times), the clients demand one file each from the server, to satisfy which the server sends coded transmissions. The rate ($R$) of such a coded caching scheme is defined as the ratio of the number of bits transmitted to the size of each file, which can be calculated as

$$R = \frac{\text{Number of transmissions in the delivery phase}}{\text{Number of subfiles in a file}}$$

when each transmission is of the same size as the subfiles. The Ali-Niesen scheme in [3] achieves $R = \frac{K(1 - \frac{\gamma}{\alpha})}{2\gamma}$, where $\gamma = 1 + \frac{\gamma F}{K}$ is the global caching gain, i.e., the number of users served by each transmission in the delivery scheme. This rate was shown to be optimal for uncoded cache placement [4]. Further, the subpacketization level used by the Ali-Niesen scheme to achieve this rate is $F = \left(\frac{K}{\log_q K}\right)^\gamma$. Note that as $K$ grows large, $F \approx 2^{KH(M/N)}$, (for constant $\frac{M}{N}$, $H(.)$ being the binary entropy). This means that the files have to be extremely large for even 50-100 clients, making the Ali-Niesen scheme impractical for applications.
scheme using projective geometries over finite fields in the line graph framework of [9]. In Section [V] we give the asymptotic analysis of the scheme proposed. We show that the scheme achieves a rate \( R = \Theta \left( \frac{K}{\log q} \right) \) (\( q \) being a prime power) for a constant cache requirement, which can be extremely small (\( \frac{N}{D} \leq \frac{1}{2} \), for some constant positive integer \( a \)). The subpacketization achieved is subexponential in \( K, F = q^{O(\log (log q)^2)} \). We provide a table in Section [V] which compares the parameters of our scheme to that of [6].

Notations and Terminology: \( \mathbb{Z}^+ \) denotes the set of positive integers. We denote the set \( \{1, \ldots, n\} \) by \([n]\) where \( n \in \mathbb{Z}^+ \). We give the basic definitions in graph theory. The sets \( V(G), E(G) \) denote vertex set and edge set of a graph \( G \) respectively, where \( E(G) \subseteq \{\{u, v\} : u, v \in V(G)\} \). All graphs considered in this paper are undirected graphs with no self loops. The neighbourhood of a vertex \( u \in V(G) \) is \( N(u) = \{v \in V(G) : \{u, v\} \in E(G)\} \). The degree of the vertex \( u \) is \( d(u) = |N(u)| \). A graph \( G \) is \( k \)-regular if \( d(u) = k \) for all \( u \in V(G) \).

Let \( |F| = \frac{M}{D} = \frac{1}{2} \). The uncached fraction \( \frac{M}{D} \) can be extremely small (\( \frac{N}{D} \leq \frac{1}{2} \), for some constant positive integer \( a \)). The subpacketization achieved is subexponential in \( K, F = q^{O(\log (log q)^2)} \). We provide a table in Section [V] which compares the parameters of our scheme to that of [6].

Lemma 1. [9] A graph \( L \) containing \( K \times D \) vertices is the line graph of a \( D \)-left-regular bipartite graph \( B(K, D, F) \) if and only if the following conditions are satisfied.

- The vertices of \( L \) can be partitioned into \( K \) disjoint cliques containing \( D \) vertices each. We denote these cliques by \( U_k : k \in K \) and call them as the user-cliques.
- Consider distinct \( k_1, k_2 \in K \). For any vertex \( v \in U_{k_1} \), there exists at most one vertex \( w \in U_{k_2} \) such that \( \{v, w\} \in E(L) \).
- For any \( k \in K \) and any vertex \( v \in U_k \), the set \( \{v\} \cup N(v) \setminus U_k \) (containing \( v \) and all adjacent vertices of \( v \) except those in \( U_k \)), forms a clique. We refer to these cliques as the subfile-cliques.
- Let \( r \) be the number of subfile-cliques in \( L \) and the subfile-cliques be denoted as \( S_i : i \in [r] \). Then the number of right vertices of \( B \) is \( r \).

Any graph \( L \) that satisfies the above conditions for some \( K \) and \( D \) is called as a line graph. Since there are \( r = F \) subfile cliques, we can denote the subfile-cliques as \( S_f : f \in F \). It also holds by the construction of \( L \) that there is at most one vertex in the intersection of any given user-clique \( U_k \) and a subfile-clique \( S_f \). Further, note that the subfile-cliques also partition the vertices of \( L \). Thus each vertex of \( L \) lies precisely in one user-clique and one subfile-clique.

Therefore the vertices of \( L \) can be indexed using a subset of \( K \times F \), i.e., \( V(L) = \{(k, f) : k \in K \times F \} \). With this notation, we have \( U_k = \{(k, f) : f \in F \} \) and \( S_f = \{(k, f) \in V(L) : k \in K \} \). Furthermore, it follows that \( E(L) = \{(k, f), (k', f')\} \subseteq V(L) : k = k' \) or \( f = f' \) but not both.

Following [9], the delivery scheme follows according to a clique cover of \( \mathbb{L}^2 \). In order to find the cliques in \( \mathbb{L}^2 \) (called transmission cliques), first we need to identify the structure of \( \mathbb{L}^2 \). It is easy to see that \( V(\mathbb{L}^2) = V(L) \). In Lemma [2] we present the conditions under which an edge exist in \( \mathbb{L}^2 \). We will use this lemma in Section [V] to identify such transmission cliques in the construction we give.

Lemma 2. Let \( \{(k_1, f_1), (k_2, f_2)\} \in V(L) \). The edge \( \{(k_1, f_1), (k_2, f_2)\} \in E(\mathbb{L}^2) \) if and only if \( k_1 \neq k_2, f_1 \neq f_2 \) and \( (k_1, f_2), (k_2, f_1) \notin V(L) \).

Proof: The If part of the lemma follows from the definition of \( \mathbb{L}^2 \). We prove the only if part here. Let \( \{(k_1, f_1), (k_2, f_2)\} \in E(\mathbb{L}^2) \). Suppose \( k_1 = k_2 \). Then by the construction of \( L \) we have \( \{(k_1, f_1), (k_2, f_2)\} \in E(L) \). Therefore \( \{(k_1, f_1), (k_2, f_2)\} \notin E(\mathbb{L}^2) \) which is a contradiction. Hence \( k_1 \neq k_2 \). Similarly \( f_1 \neq f_2 \). Suppose \( (k_1, f_2) \in V(L) \). Then \( (k_1, f_1), (k_2, f_2) \in V(L) \). By the construction of \( L \) we have \( \{(k_1, f_2), (k_1, f_1)\} \in E(L) \). Thus the edge is not in \( \mathbb{L}^2 \). Therefore \( \{(k_1, f_1), (k_2, f_2)\} \notin E(\mathbb{L}^2) \) which is a contradiction. Hence \( k_1 \neq k_2 \). Similarly \( f_1 \neq f_2 \). Suppose \( (k_1, f_2) \in V(L) \). Then \( (k_1, f_1), (k_2, f_2) \in V(L) \). By the construction of \( L \) we have \( \{(k_1, f_2), (k_1, f_1)\} \in E(L) \). Therefore \( \{(k_1, f_1), (k_2, f_2)\} \notin E(\mathbb{L}^2) \) which is a contradiction. Hence \( k_1 \neq k_2 \). Similarly \( f_1 \neq f_2 \). Suppose \( (k_1, f_2) \in V(L) \). Then \( (k_1, f_1), (k_2, f_2) \in V(L) \). By the construction of \( L \) we have \( \{(k_1, f_2), (k_1, f_1)\} \in E(L) \). Thus the edge is not in \( \mathbb{L}^2 \). Therefore \( \{(k_1, f_1), (k_2, f_2)\} \notin E(\mathbb{L}^2) \) which is a contradiction. Hence \( k_1 \neq k_2 \). Similarly \( f_1 \neq f_2 \). Suppose \( (k_1, f_2) \in V(L) \). Then \( (k_1, f_1), (k_2, f_2) \in V(L) \). By the construction of \( L \) we have \( \{(k_1, f_2), (k_1, f_1)\} \in E(L) \). Thus the edge is not in \( \mathbb{L}^2 \). Therefore \( \{(k_1, f_1), (k_2, f_2)\} \notin E(\mathbb{L}^2) \) which is a contradiction. Hence \( k_1 \neq k_2 \). Similarly \( f_1 \neq f_2 \).
\{(k_1, f_1), (k_2, f_2)\} \in E(\mathcal{L}^2) \) which is a contradiction. Hence \((k_1, f_1), (k_2, f_2) \notin V(\mathcal{L})\). Similarly \((k_2, f_1) \notin V(\mathcal{L})\).

In [9] a particular class of caching line graphs called \((c, d)\)-caching line graphs was considered. The advantage of these line graphs is that the corresponding caching scheme parameters are obtained naturally in a simple fashion. This is captured in the following definition and theorem. Our construction in Section [IV] is also based on such \((c, d)\)-caching line graphs.

**Definition 1.** [9] A caching line graph \(\mathcal{L}\) such that \(\mathcal{L}\) has a clique cover consisting of \(c\)-sided disjoint subfile cliques and \(\mathcal{L}^2\) has a clique cover consisting of \(d\)-sided disjoint cliques, for some \(c, d \in \mathbb{Z}^+\), is called a \((c, d)\)-caching line graph.

**Theorem 1.** [9] Consider a \((c, d)\)-caching line graph \(\mathcal{L}\). Then there is a coded caching scheme consisting of the caching scheme given by \(\mathcal{L}\) with \(F = \frac{Kd}{c}\) (and thus \(\frac{d}{c} = 1 - \frac{1}{K}\)), and there is an associated transmission scheme based on the clique cover of \(\mathcal{L}^2\) having rate \(R = \frac{c}{d}\).

### III. A NEW LOWER BOUND ON THE RATE

In this section, we propose a lower bound on rate of the delivery scheme for symmetric caching schemes where each subfile is stored in equal number of users. Most known schemes in literature satisfy this property to best of our knowledge. From Section [I] we know that any symmetric caching scheme can be represented by a left-regular bipartite caching graph \(B(K, D, F)\) where \(1 - \frac{d}{c} = \frac{D}{K}\). As each subfile is not cached at equal number of users, the equivalent bipartite graph with \(KD\) edges will be right regular as well, with right degree being \(K(1 - \frac{d}{c})\) for every subfile in \(B\).

We first recall a generic lower bound given in [9] based on structure of \(B(K, D, F)\) which is used in Theorem 2 to arrive at our new bound. Let \(H\) be the subgraph of \(B\) induced by the vertices \(K' \subseteq K\) and \(F' \subseteq F\). Let \(N' = \min\{|K'|, K(1 - \frac{d}{c})\}\). Let \(U = \{k_j : j \in [N']\}\) be a subset of \(N'\) vertices of \(K'\) taken in some order. For \(j \in [N']\), let \(\rho_j\) be the set of right vertices (subfiles) in \(H\) which are adjacent to \(\{k_i : i \in [j]\}\). Let \(R^*\) be the infimum of all achievable rates for coded caching problem defined by \(B\). Then, from Theorem 2 of [9],

\[
R^* F \geq \sum_{j=1}^{N'} \rho_j. \tag{1}
\]

We now obtain a lower bound for the case of symmetric caching schemes defined by bi-regular bipartite caching graphs. The proof for this bound is based on a similar ‘nested’ bound shown in [7].

**Theorem 2.** Let \(R^*\) be the infimum of all achievable rates for the coded caching problem defined by a bi-regular bipartite graph \(B\). Then

\[
R^* F \geq D + \left[\frac{D(K(1 - \frac{d}{c}) - 1)}{K - 1}\right] + \cdots + \left[\frac{1}{\frac{d}{c} + 1}\right] + \left[\frac{2}{\frac{d}{c} + 2}\right] + \cdots + \left[\frac{D(K(1 - \frac{d}{c}) - 1)}{K - 1}\right].
\]

**Proof:** Every user vertex has degree \(D = F(1 - \frac{d}{c})\) in \(B\). Consider a user vertex in \(B\) and call it as \(k_1\). So, by notations of \([1]\), \(|\rho_1| = D\). Consider the graph induced by \(K \cup N(k_1)\) vertices of \(B\). Call it \(G'\). Since \(B\) is a bi-regular graph, degree of each subfile vertex \(f \in F\) in \(B\) is exactly \(K(1 - \frac{d}{c})\). So, by pigeon-holing argument, it is not difficult to see that there exists a user with degree at least \(\left[\frac{D(K(1 - \frac{d}{c}) - 1)}{K - 1}\right]\) in \(G'\). Consider such user vertex and call it as \(k_2\). Then \(|\rho_2| \geq \left[\frac{D(K(1 - \frac{d}{c}) - 1)}{K - 1}\right]\). In general, for each \(j \in \{2, \ldots, K(1 - \frac{d}{c}) - 1\}\), for the graph induced by \(K \cup N(k_1) \cup N(k_j)\) vertices of \(B\), by pigeon-holing argument there exists a user with degree at least \(\left[\frac{D(K(1 - \frac{d}{c}) - 1)}{K - 1}\right]\). Call such user vertex as \(k_j\). Then, \(|\rho_j| \geq \left[\frac{D(K(1 - \frac{d}{c}) - 1)}{K - 1}\right]\). Running over all \(j\), and using \([1]\), we therefore get the bound in the theorem.

For a number of parameters we now compare (in Table I) the above new bound on the number of transmissions (column 4 of Table I) in an optimal scheme, with the lower bound given in [7] (given in column 5, which holds for PDA based schemes), as well as the lower bound (column 6) based on the Ali-Niesen rate \((R^* \geq \frac{\sum_{j=1}^{N'} \rho_j}{\frac{d}{c} + 1})\) as shown in [4]. The bound given in [7] used in Table I is as follows.

**Theorem 3.** [7] \(R^* F \geq \left[\frac{D(K - 1)}{K - 1}\right] + \left[\frac{D(K - 1)}{K - 2}\right] + \cdots + \left[\frac{D(K - 1)}{K - (N' - 1)}\right].\)

It can be seen that for many of the parameters, our bound is better than those in [7], [4]. Further, the last column of Table I denotes the rate achieved by the scheme in Section IV in this work, for whichever parameters are applicable.

### IV. A NEW PROJECTIVE GEOMETRY BASED SCHEME

In this section we present a new coded caching scheme using projective geometries over finite fields. We first review some basic concepts.

**A. Review of projective geometries over finite fields** [13]

Let \(k, q \in \mathbb{Z}^+\) such that \(q\) is a prime power. Consider a \(k\)-dim (we use “dim” for dimensional) vector space \(F_q^k\) over a finite field \(F_q\). Consider an equivalence relation on \(F_q^k \setminus \{0\}\) (where \(0\) represents the zero vector) whose equivalence classes are 1-dim subspaces (without \(0\) of \(F_q^k\). The set of
these equivalence classes is called the \((k - 1)\)-dim \emph{projective space} over \(\mathbb{F}_q\), and is denoted by \(PG_q(k-1)\). For \(m \in [k]\), let \(PG_q(k-1, m-1)\) denote the set of all \(m\)-dim subspaces of \(PG_q^{k}\). It is known that (Chapter 3 in [11]) \(|PG_q(k-1, m-1)|\) is equal to the \(q\)-binomial coefficient \(\binom{k}{m}_q\), where \(\binom{k}{m}_q = \frac{(q^k - 1)(q^{k-1} - 1)\cdots(q^{k-m+1} - 1)}{(q^m - 1)(q^{m-1} - 1)\cdots(q - 1)}\). The following result is known from [11].

**Lemma 3** (Chapter 3 in [11]). Consider a \(k\)-dim vector space over \(\mathbb{F}_q\). Let \(1 \leq r, s, t < k\). Then the number of \(r\)-dim subspaces intersecting a fixed \(s\)-dim subspace in a fixed \(t\)-dim subspace is \(q^{(r-t)(s-t)}\). We call such \(r\)-dim subspaces \(a\)-subspaces. For a fixed \((t-1)\)-dim subspace \(W\). By Lemma [3] we have \(|C_X| = q^{(t+1)-(m+1)}\).

We now obtain \(|C_V|\) for any \(V \in \mathbb{V}\). To do this, we will first find the number (say \(h\)) of \((m+t)\)-dim subspaces \(P \in \mathbb{P}\) intersecting the fixed \(t\)-dim subspace \(V\) in the fixed \((t-1)\)-dim subspace \(W\). By using Lemma [3] we thus have \(h = q^{(m+t+1)(t+1)}\). Now, we find the number \(g\) such that \(\sum_{V \in \mathbb{X}} g_V = P\) for some \(P \in \mathbb{P}\). Then it follows that \(|C_V| = hg\).

Now, to find \(g\), we first prove a few smaller claims.

**Claim 1:** The number of one dimensional spaces \(A\) such that \(W \oplus A = V\) is \(q^{t-1}\).

**Proof of Claim 1:** To see this, observe that to satisfy \(W \oplus A = V\), we must have \(A = span(a)\) for some \(a \in V\). Thus there are \(q^t - q^{t-1} = q^{t-1}(q - 1)\) choices for \(a\). However these are precisely \(q - 1\) vectors \(a\) whose span is the same one-dimensional subspace \(A\). Hence we have that the number of one dimensional spaces \(A\) such that \(W \oplus A = V\) is \(q^{t-1}\).

**Claim 2:** Let \(X = \{V_1, \ldots, V_{m+1}\}\) be some fixed element in \(\mathbb{X}\). The number \(N_{1} (m+1)\)- sized sets \(\{A_1, A_2, \ldots, A_{m+1}\}\) (where \(A_i, \forall i \in [m+1]\) are \(1\)-dim subspaces) such that \(\{W \oplus A_1, W \oplus A_2, \ldots, W \oplus A_{m+1}\}\) is \(X\).

**Proof of Claim 2:** By Claim 1, the number of \(A_i\) such that \(W \oplus A_i = V_i\) is \(q^{t-1}\). As \(A_i\)s can be independently chosen to get the corresponding \(V_i\)s, we thus have that \(N_1\) is \(q^{t-1}\).

**Claim 3:** The number \(g\) of \((m+1)\)-sized sets \(\{A_1, A_2, \ldots, A_{m+1}\}\) (where \(A_i, \forall i \in [m+1]\) are \(1\)-dim subspaces) such that \(\{W \oplus A_1 \oplus A_2 \oplus \cdots A_{m+1}\}\) is \(X\).

**Proof of Claim 3:** Firstly, we note that there exists a set \(\{A_1, \ldots, A_{m+1}\}\) of \(1\)-dim subspaces such that \(W \oplus A_i = P_i\) and \(A_i \neq P_i\). If there exists \(A_i\) such that \(A_i = \{\text{span}(a_i)\}\) and \(a_i \in P_i\), \(i \in [m+1]\), then we call such a set \(\{a_i : i = 1, \ldots, m+1\}\) as a \emph{generating set} of the set \(\{A_i : i = 1, \ldots, m+1\}\).

Note that given a set \(\{A_i : i = 1, \ldots, m+1\}\), we can get a generating set \(\{a_i : i = 1, \ldots, m+1\}\) by choosing any \(a_i \in A_i\). Now, suppose the set \(\{a_i : i \in [m+1]\}\) is a generating set for \(\{A_i : i \in [m+1]\}\), then it follows that \(\{c_i : i \in [m+1]\}\), for any \(c_i \in F_q\), \(i \in [m+1]\). Thus, the number of such distinct generating sets for any given set of \(1\)-dim subspaces \(\{A_i : i \in [m+1]\}\) is \(q^{m+1}\).

Now the number of ways to choose an \emph{ordered} set of vectors \(\{a_i : i \in [m+1]\}\) such that \(a_i \in P_i\) \((i \in [m+1])\),
for all \( i \in [m+1] \), is \( \prod_{i=0}^{m} (q^{m+t} - q^{t-1+i}) \). Thus, the number of (unordered) such generating sets \( \{a_i : i \in [m+1]\} \) is \( \prod_{i=0}^{m} (q^{m+t} - q^{t-1+i}) \). By arguments in the previous paragraph, it can be seen that these unordered generating sets can be partitioned into groups of \( (q-1)^{m+1} \), such that each such group includes precisely the set of all generating sets for a particular set of 1-dim spaces \( \{A_i : i \in [m+1]\} \) such that \( W \oplus \bigoplus_{i} A_i = P \).

Thus the number \( q' \) we are looking for is precisely \( \prod_{i=0}^{m} (q^{m+t} - q^{t-1+i}) \). This proves Claim 3.

We now prove that the number \( q \) of \( X \in \mathbb{X} \) such that \( \sum_{V_i \in X} V_i = P \) for some \( P \in \mathbb{P} \) is \( \prod_{i=0}^{m} (q^{m+1} - q^i) \). To see this, note that for each \( X = \{V_1, ..., V_{m+1}\} \in \mathbb{X} \) such that \( \sum_{V_i \in X} V_i = P \), there exists precisely \( q^{t-1} \) (mod \( (m+1) \)) sets \( \{A_i \in \mathbb{V} : i \in [m+1]\} \) such that \( W \oplus \bigoplus_{i} A_i = P \). By Claim 3, the total number of sets of 1-dim spaces \( \{A_1, ..., A_{m+1}\} \) such that \( W \oplus \bigoplus_{i} A_i = P \) is \( q' \), and these can be partitioned into groups each of size \( q^{t-1} \) (mod \( (m+1) \)), such that for each set \( \{A_1, ..., A_{m+1}\} \) in any particular group, the set \( X = \{V_i = W \oplus A_i : i \in [m+1]\} \in \mathbb{X} \) is the same. Thus we have that \( q = \prod_{i=0}^{m} (q^{m+1} - q^i) \).

Finally, we see that the expression for \( |C_X| = h g \) matches the lemma statement, which proves the lemma.

Note that by Lemma 4 we have the size of the subfile cliques of \( \mathcal{L} \) as \( |C X| \) (for any \( X \in \mathbb{X} \)). We now show that \( \mathcal{L} \) has a clique cover with \( d \)-sized disjoint cliques for some \( d \). Therefore \( \mathcal{L} \) is in fact a \( (c = |C X|, d \) )-caching line graph, giving raise to the main result in this section which is Theorem 4.

### C. Delivery Scheme from a clique cover of \( \mathcal{L} \)

We first describe a clique of \( \mathcal{L} \) and show that such equal-sized cliques partition \( V(\mathcal{L}) = V(\mathcal{L}^2) \). This will suffice to show the delivery scheme as per Theorem 1.

Let \( \mathcal{Y} = \{V_1, V_2, ..., V_{m+2} : V_i \in \mathbb{V}, \forall i \in [m+2] \} \) such that \( \sum_{i=1}^{m+2} V_i \in \text{PG}_q (k-1, m+t) \). We now present a clique of size \( (m+2) \) in \( \mathcal{L}^2 \).

**Lemma 5.** Consider \( \mathcal{Y} = \{V_1, V_2, ..., V_{m+2} \} \in \mathcal{Y} \). Then \( C_{\mathcal{Y}} = \{V_i, Y \setminus V_i \}, \forall V_i \in \mathcal{Y} \} \subset V(\mathcal{L}^2) \) is a clique in \( \mathcal{L}^2 \).

**Proof:** First note that \( C_{\mathcal{Y}} \) is well defined as \( V_i \not\subseteq \sum_{j \neq i} V_j \) (otherwise \( \sum_{j \neq i} V_j \) will not be a \((m+t+1)\)-dim space) and hence \( (V_i, Y \setminus V_i) \in V(\mathcal{L}) \). Consider two distinct vertices \( (V_i, Y \setminus V_i), (V_j, Y \setminus V_j) \in C_{\mathcal{Y}} \). It is clear that \( V_i \neq V_j \) and \( Y \setminus V_i \neq Y \setminus V_j \). By the construction of \( C_{\mathcal{Y}} \) we have 
\[
V_i \subseteq \sum_{j \neq i} V_j \text{ and } V_j \subseteq \sum_{i \neq j} V_i.
\]
Therefore we have \( (V_i, Y \setminus V_i), (V_j, Y \setminus V_j) \notin V(\mathcal{L}^2) \). By invoking Lemma 2 \( (V_i, Y \setminus V_i), (V_j, Y \setminus V_j) \in E(\mathcal{L}^2) \). Hence proved.

Now we show that the cliques \( \{C_{\mathcal{Y}} : Y \in \mathcal{Y}\} \) partition \( V(\mathcal{L}^2) \).

**Lemma 6.** \( \bigcup_{Y \in \mathcal{Y}} C_{\mathcal{Y}} = V(\mathcal{L}) \), where the union is a disjoint union.

**Proof:** Consider \( Y, Y' \in \mathcal{Y} \) such that \( Y \neq Y' \). By definition of \( C_{\mathcal{Y}} \), we have \( C_{\mathcal{Y}} \cap C_{\mathcal{Y}'} = \phi \). Now consider an arbitrary vertex \( (V_1, \{V_2, V_3, ..., V_{m+2}\}) \in V(\mathcal{L}) \). By the construction of \( \mathcal{L} \), \( \sum_{i=1}^{m+2} V_i \in \text{PG}_q (k-1, m+t) \). Therefore \( (V_1, \{V_2, V_3, ..., V_{m+2}\}) \) lies in the clique, \( C_{\{V_1, V_2, ..., V_{m+2}\}} \) (defined as in Lemma 5). Hence proved.

Finally we present our coded caching scheme using the caching line graph constructed above.

**Theorem 4.** The caching line graph \( \mathcal{L} \) constructed above is a \( (c = q^{m+1} \left| \frac{k-m-t}{1} \right|, d = m+2) \)-caching line graph and defines a coded caching scheme with
\[
K = \left[ \frac{k-t+1}{m+1} \right]_q \prod_{i=0}^{m} (q^{m+1} - q^i),
\]
\[
F = \left[ \frac{k-t+1}{m+1} \right]_q \prod_{i=0}^{m} (q^{m+1} - q^i) \cdot \frac{q^{m+1}}{q^i},
\]
\[
\mathcal{M} = 1 - \frac{k-t+1}{m+1} \cdot \frac{q^{m+1}}{q^i} \quad \text{and} \quad \mathcal{R} = \frac{m+2}{m+1}.
\]

**Proof:** From Lemma 4 and the notations in Lemma 1 we get the expression of \( K \) and \( D = |C_{\mathcal{Y}}| \). Further we see that the subfile cliques partition the vertices of \( \mathcal{L} \) by definition and also \( c = |C X| \) for any \( X \in \mathbb{X} \) (the size of each subfile clique). By Lemma 5 and Lemma 6, the size of the cliques of \( \mathcal{L}^2 \) is \( (m+2) \) and they partition the vertices. Hence \( \mathcal{L} \) is a \( (c = q^{m+1} \left| \frac{k-m-t}{1} \right|, d = m+2) \)-caching line graph.

Thus, we have by Theorem 1:
\[
F = \frac{KD}{c} = \left[ \frac{k-t+1}{m+1} \right]_q \prod_{i=0}^{m} (q^{m+1} - q^i) \cdot \frac{q^{m+1}}{q^i},
\]
\[
\mathcal{M} = 1 - \frac{k-t+1}{m+1} \cdot \frac{q^{m+1}}{q^i},
\]
\[
\mathcal{R} = \frac{m+2}{m+1}.
\]
This completes the proof.

V. ASYMPTOTIC ANALYSIS OF THE PROPOSED SCHEME

In this section, we analyse the behaviour of $R$, $F$ for the coded caching scheme proposed in Section IV as $1 - \frac{L}{N}$ is lower bounded by a constant and $K \rightarrow \infty$. We show that $F = o((\log K)^2)$, while $R = O(\frac{K}{\log K})$. Towards this end, we first give some bounds on $q$-binomial coefficients. These can be easily derived, however a proof is available in [10].

**Lemma 7.** [9] For non-negative integers $a, b, f$, for $q$ being some prime power,

$$q^{(a-b)b} \leq \frac{a}{b} \leq q^{(a-b+1)b}$$

$$q^{(a-f-b-1)\delta} \leq \frac{a}{f} \leq q^{(a-f-b+1)\delta},$$

where $\delta = |b - f|$.

We now proceed to analyse the asymptotics of the scheme. Throughout our analysis we assume $q$ is constant. Consider,

$$1 - \frac{M}{N} = \frac{q^m \log K}{(q^k - 1) - 1} \geq \frac{q^m \log K}{(q^k - 1) - 1}.$$

To lower bound $1 - \frac{M}{N}$ by a constant, let $k - m - t = \alpha$, where $\alpha$ is a constant. Note that $\alpha \geq 0$ as $m + t \leq k$. We have $K = \frac{k - m + 1}{1}$. We analyse our scheme as $(k-t)$ grows large. By Lemma 7 we have $q^{k-t} \leq K \leq q^{k-t+1}$. Hence we have

$$\log_q K - 1 \leq (k-t) \leq \log_q K. \quad (2)$$

The rate expression in Theorem 4 can be written as $R = \frac{K(1 - \frac{4k}{m})}{m + 2} = \frac{K(1 - \frac{4k}{m})}{m + 2}$. Therefore by using (2) we have $\frac{K(1 - \frac{4k}{m})}{m + 2} \leq R \leq \frac{(1 - \frac{4k}{m})}{m + 2}$.

Consider, $R \leq \frac{K(1 - \frac{4k}{m})}{m + 2} = \frac{K(1 - \frac{4k}{m})}{m + 2}$. Now by Taylor’s series expansion we have $1 \leq (1 - \frac{4k}{m + 2})^{-1} \leq 2$ as $K \rightarrow \infty$. Therefore we have $R \leq \frac{(1 - \frac{4k}{m})}{m + 2}$.

Consider, $R \geq \frac{K(1 - \frac{4k}{m})}{m + 2} = \frac{K(1 - \frac{4k}{m})}{m + 2}$. Now if $\alpha \geq 2$, by Taylor’s series expansion we have $1 \leq (1 - \frac{4k}{m + 2})^{-1} \leq 2$ as $K \rightarrow \infty$. Therefore we have $R \leq \frac{K(1 - \frac{4k}{m})}{m + 2}$. If $\alpha \in \{0, 1\}$, then $R \geq \frac{K(1 - \frac{4k}{m})}{m + 2}$.

Hence $R = \Omega(\frac{K}{\log K})$. Therefore $R = \Theta(\frac{K}{\log K})$.

We now obtain the asymptotics for subpacketization $F$. By Lemma 7 and from the expression of $F$ in Theorem 4 we have

$$F = \frac{K}{m + 1} \frac{m + 1}{q} \frac{(q^m - 1)}{m + 1} \frac{(q^m - 1)}{m + 1}.$$
