Synthesis of unsymmetrical NCN’ and PCN pincer palladacycles and their catalytic evaluation compared with a related SCN pincer palladacycle†‡

Gavin W. Roffe, Graham J. Tizzard, Simon J. Coles, Hazel Cox and John Spencer

1-(3-(Pyridin-2-yl)phenyl)methanamine derivatives have been synthesized and underwent C–H bond activation to afford unsymmetrical NCN’ pincer palladacycles, which were characterised in the solid state. 2-Pyridinyl-phenol and -benzyl alcohols were then used as precursors to unsymmetrical PCN pincer palladacycles. Catalytic applications, where the palladacycle remains in the Pd(II) state, have been carried out and show good activity and selectivity.

Introduction

Palladacycles contain a covalent Pd–C bond intramolecularly stabilised by a coordinating group such as an amine, phosphine or thioether and have been extensively studied since their discovery in the mid-1960s.1 Pincer palladacycles, where a tridentate ligand can coordinate to palladium were first synthesized by Shaw and Moulton in 1976.2 However, the field of palladacycle-mediated catalysis only truly gathered momentum after the seminal discovery by Herrmann and Beller et al.3,4 that their eponymous palladacycle (Fig. 1) was highly active in catalytic C–C bond coupling reactions. Since, a number of reviews and books have been published covering the wide array of catalytic applications.5–14 The majority of pincer palladacycles are symmetrical, such as I (Fig. 2).15 However, unsymmetrical analogues such as II (Fig. 2),16 have been explored,17 and may provide a greater opportunity to fine tune catalysis due to the potential hemilability of the ligand18 and the ability to influence catalytic activity by altering the steric and electronic properties of the donor atoms.19,20

The synthesis of NCN pincers can be complicated compared with the analogous PCP and SCS pincers due to the hard-ligand (amine) soft-acid (metal) mismatch between palladium and nitrogen. This results in competition in forming the kinetic product III or the thermodynamic pincer product IV (Scheme 1).21 Hence, incorporating functional groups in the mutual ortho position such as SiMe3 or Br can be beneficial in their synthesis, compared with C–H activation routes.8 However, this is less attractive synthetically, since an additional step is required in making the functionalised ligand.

Examples of unsymmetrical PCN pincer palladacycles (Fig. 3) are synthesised by C–H bond activation or chloropalla-
A potential route to phosphorus containing palladacycles is via phenolic or benzylic alcohols, such as that by Eberhard et al., in the formation of mixed 5-,6-membered PCP', and 5-,5-pincer palladacycles (Fig. 3) containing both phosphine and phosphinite groups.

Palladacycles normally act as a reservoir of catalytically active Pd(0) species in applications such as the Suzuki–Miyaura/Heck reaction. Other catalytic applications of pincer palladacycles utilise the palladium in its Pd(II) oxidation state, retaining its ligand structure, and are more likely to take advantage of the tuning abilities of the unsymmetrical ligand design. The use of pincer palladacycles as a Lewis acid catalyst in an aldol condensation (Scheme 2) demonstrated the ability to change the stereochemical outcome of the reaction depending on the ligand donor atoms. Another application utilising pincer palladacycles in Pd(II) catalysis, is in the coupling of vinyl epoxides and boronic acids using a symmetrical SeCSe palladacycle (Scheme 3).

Unsymmetrical pincer palladacycles are relatively rare and their synthesis and that of their respective ligands often poses a greater challenge than for their symmetrical counterparts. Given some distinct advantages of employing unsymmetrical pincer palladacycles in catalytic applications, such as the tandem catalysis reported by Szabó et al., recent work in our group has focused on a robust synthetic route to useful, modular unsymmetrical ligands and their pincer palladacycles. The present work is focused on the synthesis of several new unsymmetrical nitrogen-based pincer ligands, denoted NCN', their respective palladacycles, phosphinite PCN pincer palladacycles, and catalytic evaluation in aldol condensation and vinyl epoxide coupling reactions in comparison to a related SCN pincer palladacycle.

**Results and discussion**

**NCN' ligand synthesis**

The simple biaryl motif 1 was deemed to be a potentially useful precursor to NCN' pincer ligands. 1 was formed via a Suzuki–Miyaura (SM) coupling and several catalysts, Pd(PPh₃)₄, Pd(dppf)Cl₂, Pd(OAc)₂ and Buchwald’s XPhos Pd G2 catalyst were trialled in order to optimise its yield (Table 1). It was found that Pd(dppf)Cl₂ (Pd-118) was the catalyst of choice utilising microwave-mediated (MW) synthesis (Table 1, entry 4).

Reductive amination of 1 with HNMe₂·HCl was attempted in order to synthesise the requisite unsymmetrical NCN' ligand with the dimethyl amine and pyridine groups ideally placed to promote C–H activation towards the corresponding palladacycle. Initially sodium triacetoxyborohydride proved unsuccessful although the use of titanium isopropoxide/sodium borohydride furnished the product 2a in 81% yield (Scheme 4). Next, we attempted reductive aminations with NEt₃H using both of the above conditions but to no avail.
Given that the reductive amination procedure proved ineffectual, an alternative synthesis was devised. In previous work,\textsuperscript{29} we have shown the synthesis of the benzylic bromide \textsuperscript{4}, via benzylic alcohol \textsuperscript{3} (Scheme 5) can allow late stage diversification via nucleophilic substitution by sulphur nucleophiles.\textsuperscript{29} Hence, the corresponding nucleophilic displacement of \textsuperscript{4} was undertaken with nitrogen nucleophiles, yielding NCN' ligands \textsuperscript{2b} and \textsuperscript{2c} in excellent yield (Scheme 5).

**NCN' palladacycle synthesis**

Ligands \textsuperscript{2a-c} were then selected for C–H activation towards the palladacycle products. Refluxing the ligand in AcOH in the presence of Pd(OAc)\textsubscript{2}, followed by salt metathesis yielded the desired monomeric palladacycles \textsuperscript{5a}–\textsuperscript{5c} (Scheme 6).

The yields for forming these palladacycles are disappointing, due to significant formation of Pd black, and therefore an optimisation study for the synthesis of \textsuperscript{5c} was attempted (Table 2). Changing the solvent to MeOH (entry 2), the palladium source to \textit{in situ} generated Pd(MeCN)\textsubscript{4}(BF\textsubscript{4})\textsubscript{2} (entry 3),\textsuperscript{33} and a transcyclopalladation (entry 4)\textsuperscript{34} using Pd\textsubscript{2}(dmba)\textsubscript{2}Cl\textsubscript{2} (Table 2) were attempted. It was found that indeed, the initial Pd(OAc)\textsubscript{2} in AcOH method proved to be the most effective for palladation (entry 1).

However, literature yields for NCN pincers are often low, with several examples provided using Pd(OAc)\textsubscript{2} as the palladium source (Table 3), showing the wide range of yields achieved for the key C–H bond activation step from the corresponding NCN pincer ligands. Shaw's earlier work, in contrast, showed yields for PCP pincers of around 75%.\textsuperscript{2}

In order to delve into such poor yields, we looked at the stability of \textsuperscript{5c} in refluxing \textit{d}_\textsubscript{4} acetic acid over time \textit{via} \textit{\textsuperscript{1}H} NMR, which showed no degradation of the palladacycle over time, under the conditions used for C–H activation. We also contemplated an oxidative addition of a Pd(0) salt to a bromide,\textsuperscript{38} although attempts to \textit{ortho}-brominate \textsuperscript{2c} were unsuccessful.

**PCN palladacycle synthesis**

The synthetic route to unsymmetrical NCN' pincer palladacycles has been modified to provide a route to unsymmetrical PCN pincer palladacycles. The synthesis of phosphinite palladacycles has been shown by Eberhard \textit{et al.}\textsuperscript{39} from a benzyl alcohol using CIPR\textsubscript{2}, and therefore the benzyl alcohol \textsuperscript{3} was used as the starting point for synthesis of a PCN pincer palladacycle. Due to the air sensitivity of the PCN ligand, after

reaction with ClPPh₂, C–H bond activation using Pd(OAc)₂ in AcOH was performed in situ (Scheme 8). This synthesis yields a mixed 5-,6-membered palladacycle, and for direct comparison with our 5-,5-membered SCN₂⁹ and NCN₉ pincer palladacycles, a phenolic alcohol was synthesised (Scheme 7). Using the phenolic (6) and benzylic alcohols (3), the synthesis of PCN pincer palladacycles was undertaken (Scheme 8). The PCN pincer palladacycle structures were also confirmed using X-ray crystallography (Fig. 5).

Growth of crystals of 5a–e and 7a and 7b by slow evaporation of CH₂Cl₂ from a saturated solution allowed their structures to be determined by X-ray diffraction (Fig. 4 and 5). All structures were as expected, with the metal in a distorted square planar arrangement.

Compound 5a crystallises in the monoclinic Pc space group with two independent molecules in the asymmetric unit. These are subject to π–π interactions (benzene centroid-pyridine centroid distances: 3.564 Å and 3.715 Å, offsets: 1.301 Å and 1.386 Å respectively). These pairs of molecules form layers with a ‘herringbone’ arrangement propagating along the crystallographic b and c axes.

The structure 5b crystallises in the monoclinic P2₁/c space group with two independent molecules in the asymmetric unit. The structure is formed from corrugated layers of molecules propagating along the crystallographic a and b axes with each alternate layer consisting of the same crystallographically-independent molecules.

The structure 5c crystallises in the monoclinic P2₁/n space group. The structure consists of π–π stacks (benzene centroid–pyridine centroid distances: 3.616 Å and 3.075 Å, offsets: 1.319 Å and 1.617 Å respectively) along the crystallographic c axis formed of alternating molecules related by inversion. There are weak C–H⋯O (C2⋯O1 = 3.458(3) Å and C8⋯O1 = 3.371(3) Å) interactions between the stacks which lead to the formation of corrugated layers along the a and b axes.

Table 3  Literature yields for palladation

| Entry | Palladacycle | Yield/% |
|-------|--------------|---------|
| 1     | V₁⁵⁰         | 17–70   |
| 2     | VI₁⁶⁶        | 12–54   |
| 3     | VII₁⁷⁴       | 3       |

* Depending on R group.
Structure 7a crystallises in the monoclinic \(P2_1/n\) space group. The structure consists of columns of molecules close-packed along the crystallographic 21 screw axis parallel to the b axis with π-π interactions to neighbouring columns via the phenyl pyridine moieties (centroid–centroid distance: 3.894 Å, offset: 1.322 Å).

Structure 7b crystallises in the lower symmetry triclinic, \(P\) space group. The structure is comprised of close-packed discrete layers parallel to the ac plane. These layers in turn are made up of close-packed ‘chains’ of C–H⋯O (C19⋯O1 = 3.405(2) Å) dimers with π-π interactions between neighbouring dimers via the phenyl pyridine moieties (centroid–centroid distance: 3.653 Å, offset: 1.098 Å). Structures 5a–c and 7a–b were given CCDC numbers 1038592, 1038593, 1038594, 1476634 and 1476635 respectively.

**Catalytic investigation**

Next, 5c, 7a and 7b were tested in the catalytic aldol condensation (Scheme 2) and compared with a previously published SCN pincer palladacycle by our group (Fig. 6) \(^{29}\) along with commercially available \(\text{PdCl}_2(\text{dtbpf})\) and \(\text{Pd(OAc)}_2\). The results are presented in Table 4, alongside the published data by Szabó and co-workers for symmetrical PCP and SCS pincer palladacycles, as well as an unsymmetrical PCS pincer palladacycle (Scheme 2). \(^{27}\)

![Scheme 2. Previously published SCN pincer palladacycle by our group.](Image 6)

**Table 4.** Aldol condensation results obtained using pincer palladacycles, and commercially available palladium catalysts.

| Entry | Catalyst | Linear\%/ | Branched\%/ | Yield\% |
|-------|----------|-----------|-------------|---------|
| 1     | 7a        | 85/15     |             | 99      |
| 2\(^{27}\) | PCP\(^{6}\) | 82/18     |             |         |
| 3     | 7b        | 73/27     |             |         |
| 4\(^{27}\) | SCS\(^{6}\) | 59/41     |             |         |
| 5     | 5c        | 59/41     |             | 93      |
| 6     | \(\text{Pd(OAc)}_2\) | 58/42     |             |         |
| 7     | 8         | 57/43     |             | 99      |
| 8\(^{27}\) | PCS\(^{6}\) | 57/43     |             |         |
| 9     | \(\text{PdCl}_2(\text{dtbpf})\) | 56/44     |             |         |

\(^{a}\) Performed in duplicate, average of two runs. \(trans/cis\) ratio determined by crude \(^1\)H NMR of the resulting mixture. Reaction conditions: methylisocyanoacetate (1 eq.), benzaldehyde (1 eq.), \(\text{IPr}_2\text{EtN} (0.1 \text{ eq.}), [\text{Pd}] (1 \text{ mol}%), \text{DCM} (5 \text{ cm}^3), 24 \text{ h, rt.} \(^{b}\) Scheme 2.

The results presented in Table 4 show that the family of palladacycles synthesised by our group, with SCN, NCN’ and PCN examples, provides the opportunity to fine tune catalytic activity, with the choice of donor group influencing the stereochemical outcomes of the aldol condensation. The novel PCN pincer palladacycle 7a provides the highest trans selectivity of all catalysts tested, and slightly more than the literature PCP example, whereas the SCN and NCN’ provide a greater proportion of the cis product. \(^{27}\)

![Fig. 7 Symmetrical SeCSe pincer palladacycle.](Image 7)

**Table 5.** Vinyl epoxide coupling to phenylboronic acid using pincer palladacycles.

| Entry | Catalyst | Linear\%/ | Branched\%/ | Yield\% |
|-------|----------|-----------|-------------|---------|
| 1\(^{28}\) | SeCSe | 92    | 8   | 94     |
| 2     | SCS      | 78    | 22  | >99    |
| 3     | 7b       | 66    | 34  | 66     |
| 4     | 7b       | 64    | 36  | 96     |
| 5     | 8        | 64    | 36  | 96     |
| 6     | 5c       | 60    | 40  | 84     |

\(^{a}\) Performed in duplicate, average of two runs. Linear/branched ratio determined by crude \(^1\)H NMR of the resulting mixture. Reaction conditions: 2-vinyl oxirane (1 eq.), PhB(OH)\(_2\) (1.2 eq.), \(\text{Cs}_2\text{CO}_3\) (2 eq.), [\text{Pd}] (4 mol%), 10:1 THF: \text{H}_2\text{O} (3 cm\(^3\)), 24 h rt.

In addition, catalysis of the coupling of a vinyloxirane and phenylboronic acid was tested, using the NCN’, SCN and PCN pincer palladacycles, and compared to literature SeCSe results shown in Fig. 7\(^{,28}\) and our new results using the symmetrical SCS palladacycle (Scheme 2). The coupling and results are presented in Table 5.

The results presented in Table 5 show that the symmetrical pincer palladacycles, SeCSe and SCS achieve the greatest linear selectivity (>78%), whereas the unsymmetrical pincer palladacycles achieve a higher proportion of the branched product (>34%). Clearly the presence of unsymmetrical pincer palladacycles is having an effect of the stereochemical outcome of the reaction, increasing the proportion of the branched product.

**Conclusions**

The simple synthesis of three NCN’ ligands has been shown. Their C–H activation yielded three new NCN’ pincer palladacycles. Similarly, two novel PCN pincer palladacycles were syn-
sidered in two Pd(II)-mediated reactions, an aldol condensation and vinyl epoxide coupling. It was found that in the aldol condensation, the ability to fine tune the stereocchemical outcome of the reaction is possible, by varying the donor atoms in the palladacycle catalyst. It was also shown in the vinyl epoxide coupling that the unsymmetrical pincer palladacycles achieve different product ratios than the symmetrical palladacycles tested, demonstrating the potential benefits of unsymmetrical palladacycles in catalytic applications.

Further work is being undertaken towards varying the families of unsymmetrical palladacycles, supported by DFT investigations into their bonding properties and reactivity. Moreover, it is hoped that such simple synthetic routes to unsymmetrical pincer ligands may encourage others to employ these in other areas of transition metal chemistry and catalysis.

### Experimental

#### General details

Solvents and chemicals were purchased from commercial suppliers and used without further purification, with reactions taking place open to atmosphere and moisture.

#### Instrumentation

1H and 13C spectra were recorded on either a Varian 400 or 500 MHz spectrometer. HRMS were obtained on an ESI mass spectrometer using a Bruker Daltonics Apex III, with source Apollo ESI, using methanol as the spray. Flash chromatography was performed on an automated ISCO RF75. GC measurements were obtained using a Perkin Elmer Autosystem XL Gas Chromatograph, utilizing a flame ionization detector, and a Supelco MDN-5S 30 m × 0.25 mm × 0.25 µm column, a XL Gas Chromatograph, utilizing a flame ionization detector.

The catalytic applications of the NCN, SCN and PCN pincer palladacycles, along with several other examples were considered in two Pd(II)-mediated reactions, an aldol condensation and vinyl epoxide coupling. It was found that in the aldol condensation, the ability to fine tune the stereocchemical outcome of the reaction is possible, by varying the donor atoms in the palladacycle catalyst. It was also shown in the vinyl epoxide coupling that the unsymmetrical pincer palladacycles achieve different product ratios than the symmetrical palladacycles tested, demonstrating the potential benefits of unsymmetrical palladacycles in catalytic applications.

Further work is being undertaken towards varying the families of unsymmetrical palladacycles, supported by DFT investigations into their bonding properties and reactivity. Moreover, it is hoped that such simple synthetic routes to unsymmetrical pincer ligands may encourage others to employ these in other areas of transition metal chemistry and catalysis.
(0.83 mmol, 186 mg) were dissolved in AcOH (15 cm³) and stirred at reflux (125 °C) for 3 hours. The solvent was removed in vacuo, and reconstituted with CH₂Cl₂ (5 × 50 cm³) to remove any residual acetic acid. The crude mixture was dissolved in MeOH (10 cm³) and LiCl (excess) was added. The mixture was stirred at rt for 30 min. The solvent was removed in vacuo, and the crude mixture dissolved in CH₂Cl₂ (25 cm³) and H₂O (25 cm³). The crude product was extracted using CH₂Cl₂ (2 × 25 cm³), washed with H₂O (3 × 25 cm³). The combined organic layers were dried over MgSO₄, filtered, and the solvent removed in vacuo. The crude mixture was dissolved in CH₂Cl₂ (25 cm³) and H₂O (25 cm³). The crude product was extracted using CH₂Cl₂ (2 × 35 cm³) and H₂O (10 cm³) and NaCl (13.0 mmol, 761 mg) was added. The mixture was stirred at rt for 3 hours. The solvent was removed in vacuo, and the crude mixture dissolved in CH₂Cl₂ (35 cm³) and H₂O (35 cm³). The crude product was extracted using CH₂Cl₂ (2 × 35 cm³), washed with H₂O (2 × 25 cm³) and brine (25 cm³). The organic layers were dried over MgSO₄, filtered, and the solvent removed in vacuo.

The crude product was purified by flash column chromatography (7:3 CH₂Cl₂: EtOAc) yielding 250 mg of the expected product (9:1 CH₂Cl₂: ethyl acetate) yielding 59 mg of the expected product 5a as a yellow solid in 10% yield. ²H NMR (500 MHz, chloroform-d) δ 9.06 (d, J = 5.5, 1.6, 0.7 Hz, 1H), 7.80 (ddd, J = 7.8, 7.8, 1.7 Hz, 1H), 7.58 (d, J = 7.8 Hz, 1H), 7.27–7.25 (m, 1H), 7.17 (ddd, J = 7.6, 5.6, 1.4 Hz, 1H), 7.09 (dd, J = 7.6, 7.6 Hz, 1H), 6.92 (d, J = 7.6 Hz, 1H), 4.13 (s, 2H), 3.08 (s, 2H). ¹³C NMR (126 MHz, chloroform-d) δ 165.1, 163.6, 152.4, 144.5, 142.4, 138.7, 124.8, 123.6, 122.6, 121.2, 118.5, 69.9, 62.8 (2C), 59.6. 39.6 Hz. HRMS. Calcd for [C₁₆H₁₉N₂Pd⁺] 359.0370. Found 359.0359. Anal. Calcd for [C₁₆H₁₉N₂PdCl]·C₈H₈: C, 47.8; H, 4.34; N, 7.09. Found: C, 48.59; H, 4.42; N, 6.97.

### 3-(Pyridin-2-yl)phenol (6).
3-{Hydroxyphenyl}benzonic acid (3.59 mmol, 496 mg), 2-bromopyridine (3.59 mmol, 0.342 cm³), Pd[PPh₃]₄ (0.14 mmol, 164 mg), KPO₃ (7.16 mmol, 1.52 g), H₂O (10 cm³), toluene (7.5 cm³) and EtOH (5 cm³) were added to a sealed 35 cm³ microwave vial and stirred under microwave irradiation (maximum power 300 W, dynamic heating) at 150 °C for 20 min. The reaction was cooled, and the solvent removed in vacuo. The mixture was diluted with H₂O (25 cm³) and Et₂O (25 cm³), washed with H₂O (2 × 25 cm³) and brine (25 cm³). The combined organic layers were dried over anhydrous MgSO₄, filtered, and concentrated in vacuo.

The crude material was purified using flash column chromatography (8:2 CH₂Cl₂: EtOAc) yielding 250 mg of the expected product 6 as a clear liquid in 73% yield. ²H NMR (500 MHz, chloroform-d) δ (ppm): 9.51 (d, 1H), 8.63 (d, J = 4.4 Hz, 1H), 7.86–7.83 (m, 2H), 7.51 (s, 1H), 7.47 (d, J = 7.9 Hz, 1H), 7.34–7.32 (m, 1H), 7.24 (d, J = 7.9, 7.9 Hz, 1H), 6.83 (d, J = 7.9 Hz, 1H). ³¹C NMR (126 MHz, chloroform-d) δ (ppm): 158.2, 156.5, 149.9, 140.5, 137.6, 130.2, 120.6, 117.7, 116.5, 113.8. HRMS. Calcd for [C₁₁H₂NO + H] 172.0757. Found 172.0755.

### Palladacycle (7a).
Under an argon atmosphere 3-(pyridin-2-yl)phenylmethanol (418 mg, 2.26 mmol), NEt₃ (0.63 cm³, 4.52 mmol), and DMAP (spatula tip) were dissolved in Et₂O (5 cm³) and cooled to 0 °C. CIPPH₂ (0.41 cm³, 2.22 mmol) was added dropwise to the solution forming a white precipitate. The reaction was warmed to room temperature and stirred for 3 h. The crude mixture was filtered under an argon atmosphere and the solvent removed in vacuo. Pd(OAc)₂ (687 mg, 1.06 mmol) was added to the crude intermediate, dissolved in AcOH (5 cm³), and heated at reflux o/n. The solvent was removed in vacuo and reconstituted with CH₂Cl₂ to remove residual AcOH. NaCl (1.16 g, 19.9 mmol) was added to the crude mixture, which was then dissolved in MeCN (10 cm³) and H₂O (10 cm³), and stirred at room temperature o/n. The solvent was removed in vacuo, and the crude mixture dissolved in CH₂Cl₂ and separated using a hydrophobic frit. The crude product was purified using flash column chromatography (7:3 CH₂Cl₂: EtOAc) yielding 383 mg of the expected product (7a) as a yellow solid in 29% yield. ²H NMR (500 MHz, chloroform-d) δ (ppm): 9.38 (s, 1H), 8.08–8.03 (m, 4H), 7.88–7.79 (m, 2H), 7.63 (d, J = 7.6 Hz, 1H), 7.52–7.44 (m, 6H), 7.30 (d, J = 6.6 Hz, 1H), 7.19 (dd, J = 7.6, 7.6 Hz, 1H), 7.03 (d, J = 6.6 Hz, 1H), 4.83 (d, J = 19.6 Hz, 2H). ³¹C NMR (126 MHz, chloroform-d) δ (ppm): 163.3, 151.9, 149.4, 148.2, 139.2 (2C), 136.5, 133.2 (d, JPC:C = 13.4 Hz), 130.0 (d, JPC:C = 59.8 Hz, 2C), 131.7 (d, JPC:C = 2.4 Hz), 128.4 (d, JPC:C = 2.0 Hz, 4C), 128.3 (d, JPC:C = 11.6 Hz, 4C), 125.4, 124.1, 122.5 (d, JPC:C = 3.4 Hz), 118.5 (d, JPC:C = 1.9 Hz), 72.1 (d, JPC:C = 2.8 Hz). ³¹P NMR (162 MHz, chloroform-d) δ (ppm): 123.27. HRMS. Calcd for [C₁₄H₁₂NOP₃]+ 345.0578. Found 345.0564. Anal. Calcd for [C₁₄H₁₂NOP₃]Cl: C, 47.54; H, 4.34; N, 7.93. Found: C, 47.54; H, 4.34; N, 7.84.
Found 474.0239. Anal. Caled for C_{24}H_{19}NOPdCl: C, 56.49; H, 3.75; N, 2.75. Found: C, 56.48; H, 3.82; N, 2.83.

**Palladacycle (7b)**. Same method as 7a yielding 409 mg of the expected product (7b) as a yellow solid in 22% yield. $^1$H NMR (500 MHz, chloroform-d) $\delta$ (ppm): 9.16 (s, 1H), 8.06–8.02 (m, 4H), 7.88 (7.8, 7.8 Hz, 1H), 7.72 (d, 7.8 Hz, 1H), 7.54–7.46 (m, 5H), 7.34 (s, 1H), 7.29–7.26 (m, 2H), 7.15 (dd, 7.8, 7.8 Hz, 1H), 6.96 (d, 7.8 Hz, 1H). $^{13}$C NMR (126 MHz, chloroform-d) $\delta$ (ppm): 164.5 (d, 3$J_{PC}$ = 3.0 Hz), 162.6 (d, 3$J_{PC}$ = 10.0 Hz), 149.5, 145.8, 139.3, 133.2 (d, $J_{PC}$ = 55.2 Hz), 132.1 (d, $J_{PC}$ = 2.5 Hz), 131.6 (d, $J_{PC}$ = 14.8 Hz), 128.9 (d, $J_{PC}$ = 11.9 Hz), 126.9, 123.1 (d, $J_{PC}$ = 3.4 Hz), 119.0, 118.0, 113.5 (d, $J_{PC}$ = 17.2 Hz), 107.1. $^{31}$P NMR (162 MHz, chloroform-d) $\delta$ (ppm): 155.3.

HRMS. Caled for [C$_2$H$_7$N$^+$NOPdCl]$: 460.0083. Found: 460.0080. Anal. Caled for C$_{24}$H$_{19}$NOPdCl: C, 55.67; H, 3.45; N, 2.82. Found: C, 55.76; H, 3.58; N, 2.84.

**Aldol condensation reaction**

Under an argon atmosphere, the palladium catalyst (0.01 eq.) was dissolved in DCM. The methylisocyanacetate (1 eq.), benzaldehyde (1 eq.) and DIPEA (0.1 eq.) were added to the reaction vessel. The reaction was stirred at rt for 24 h, then the reaction diluted with DCM (10 cm$^3$), washed with H$_2$O (5 cm$^3$), and separated using a hydrophobic frit. The solvent was then removed in vacuo yielding the mixture of linear and branched products.

$^1$H NMR (500 MHz, chloroform-d) $\delta$ 7.47–7.27 (m, 12H), 5.75 (d, $J$ = 11.1 Hz, 1H, cis), 5.70 (d, $J$ = 7.8 Hz, 1H, trans), 5.10 (dd, 11.1, 2.0 Hz, 1H, cis), 4.65 (dd, 7.8, 2.2 Hz, 1H, trans), 3.85 (s, 3H, trans), 3.21 (s, 3H, cis).

**Vinyl epoxide coupling**

The palladium catalyst (4 mol%), phenylboronic acid (1.2 eq.) and Cs$_2$CO$_3$ (2 eq.) were dissolved in 10 : 1 THF : H$_2$O (3 cm$^3$). The 2-vinylxirane was then added (1 eq.), and the reaction was stirred at rt for 24 h. The solvent was removed in vacuo, dissolved in DCM (5 cm$^3$), washed with H$_2$O (5 cm$^3$), and separated using a hydrophobic frit. The solvent was then removed in vacuo yielding the mixture of linear and branched products.

$^1$H NMR (500 MHz, chloroform-d) $\delta$ 7.40–7.25 (m, 10H), 6.03 (dd, $J$ = 18.0, 10.7, 7.3 Hz, 1H, branched), 5.91–5.85 (m, 1H, linear), 5.77–5.69 (m, 1H, linear), 5.24–5.19 (m, 2H, branched), 4.13 (s, 2H, linear), 3.88–3.81 (m, 2H, branched), 3.55 (dt, 7.3, 7.3 Hz, 1H, branched), 3.40 (d, 6.7 Hz, 2H, linear), 1.66 (s, 1H, branched), 1.45 (s, 1H, linear). $^{13}$C NMR (100 MHz, chloroform-d) $\delta$ 140.7 (branched), 140.0 (linear), 138.3 (branched), 131.5 (linear), 130.3 (linear), 128.7 (branched), 128.5 (linear), 128.4 (linear), 126.9 (branched), 126.1 (linear), 117.0 (branched), 66.1 (branched), 63.5 (linear), 52.5 (branched), 38.6 (linear).

**Acknowledgements**

We would like to thank the University of Sussex for a studentship (GWR), Christopher Dadswell for the support and use of the GC equipment, and Johnson Matthey for the loan of palladium salts. We would also like to thank Dr Alaa Abdul-Sada at the University of Sussex and the EPSRC Mass Spectroscopy Facility (University of Swansea) for mass spectrometry services.
