It is highly promising to design and develop efficient and economical electrocatalysts for oxygen evolution reaction (OER) in alkaline solution. In this work, we prepare FeCoNi sulfide composites (including FeS, Co₃S₄, and Ni₃S₄) derived from in situ sulfurization of precursor oxides on carbon cloth (CC), which are used to become an OER catalyst. Such catalyst shows excellent OER performance, low overpotential, small Tafel slope, and high electrochemical stability, and it is a promising electrocatalyst for OER in alkaline media.

Keywords: oxygen evolution reaction, electrocatalyst, FeCoNi sulfides, nanowires array, in situ sulfurization

INTRODUCTION

The excessive consumption of fossil energy and the resulting serious environmental problems have triggered strong demand for renewable alternative energy (Chow et al., 2003; Zheng et al., 2014). Hydrogen energy is regarded as a clean and ideal energy carrier that could replace fossil energy (Dresselhaus and Thomas, 2001; Zheng et al., 2017, 2018b). Electrochemical water splitting provides us a promising strategy to largely produce hydrogen (Turner, 2004; Lu et al., 2017). However, hydrogen evolution is seriously restricted by anodic water oxidation due to the multi-electron transfer process and high activation energy barrier (Yin et al., 2010; Yang et al., 2017; Ke et al., 2018; Zheng et al., 2018a; Tang et al., 2019). Therefore, efficient catalysts to reduce activation energy should be developed to boost the water oxidation process. Noble metal oxides (RuO₂ and IrO₂) exhibit excellent catalytic characters in oxygen evolution reaction (OER), but their widespread applications are limited due to scarce resources and high costs (Lee et al., 2012; Reier et al., 2012). Hence, it is necessary to develop efficient and economical OER electrocatalysts.

In recent years, transition-metal oxides and hydroxyl oxide have attracted great interest for catalysts (Lu et al., 2016; Guo et al., 2017; Zhang et al., 2018). Specifically, ferric oxyhydroxide (FeOOH) has shown efficient activity for the OER process (Chemelewski et al., 2014; Luo et al., 2017; Park et al., 2017). Regardless of its abundant reserves and low cost, its performance for OER has certain disparities in comparing with the noble metal catalysts. Many ways have been taken to improve catalysis performance, such as enhancing the conductivity of materials, increasing the specific surface area of materials, doping heteroatom modification, and so on (Feng et al., 2016a,b; Kuang et al., 2017; Li F. et al., 2018). Research shows that transition metal sulfides have better oxygen evolution catalysis performance than oxides because transit metal sulfides have diverse element composition, controllable electronic structure, and fast charge transfer speed (Liu et al., 2016; Chai et al., 2018; Li H. et al., 2018; Zhang et al., 2018).
In this manuscript, we design and develop FeCoNiS sulfides derived from \textit{in situ} sulfurization of precursor oxides on carbon cloth (CC) through two-step hydrothermal methods. At first, FeCoNi-FeOOH nanoarray on CC is prepared through hydrothermal method. Second, FeCoNiS sulfides derived \textit{from in-situ} sulfurization is prepared through the second hydrothermal method. It shows excellent OER activity needing overpotentials of 220.5 and 269.9 mV to attain current densities of 10 and 100 mA cm\textsuperscript{-2} in 1.0 M KOH. It is a promising electrocatalyst for OER in alkaline media.

**RESULTS AND DISCUSSIONS**

X-ray diffraction (XRD) patterns of these catalysts are shown in Figure 1A. There are two broad diffraction peaks on the bottom curve, which are the amorphous peaks of CC. The middle curve is the XRD pattern of the precursor oxides without sulfide treatment. The peaks at 11.95, 16.87, 26.91, 35.26, 46.69, 56.21, and 64.78° can be indexed to the (110), (200), (310), (211), (411), (521), and (541) planes of FeOOH phase (PDF No. 97-003-1136). The XRD pattern of the product after sulfide treatment is on the top. The diffraction peak intensity is obviously lower than that of the middle curve. For better structural analysis of the product, the powder of the precursor oxides and sulfide products scraped from CC are characterized by XRD again. XRD curves are shown in Figures 1B,C. The main component of precursor oxides is still FeOOH. Considered that Co and Ni are in the precursor, we name the precursor as FeCoNi-FeOOH. The XRD curve of sulfide product shows that there are new phases, including Fe\textsubscript{3}O\textsubscript{4} (PDF No. 97-005-0272), FeS (PDF No. 04-003-4477), Ni\textsubscript{3}S\textsubscript{4} (PDF No. 97-003-6721), and Co\textsubscript{3}S\textsubscript{4} (PDF No. 00-047-1738). Part of FeOOH is reduced to Fe\textsubscript{3}O\textsubscript{4}, so the product is named FeCoNiS-FeO\textsubscript{x}.

Scanning electronic microscopy (SEM) pattern of the precursor (FeCoNi-FeOOH) is shown in Figure 2A. There are specific and uniform nanowires array on the surface of CC. SEM pattern of FeCoNiS-FeO\textsubscript{x} is shown in Figure 2B. Obviously, the precursor (FeCoNi-FeOOH) nanowires are smooth, and the product (FeCoNiS-FeO\textsubscript{x}) is relatively rough. This means that the product has structural change after sulfidation, which corresponded to the XRD patterns in Figures 1B,C. The catalyst nanowire feature is also shown in transmission electron microscopy (TEM) characterization (Figure 2C). Image taken from the product shows about 50-nm-thick nanowires. High-resolution TEM (HRTEM) reveals that the product is highly crystallized with well-resolved lattice fringes (Figure 2D). The interplanar spacing of 0.331 nm could be assigned to the (310) plane of FeOOH.

The corresponding energy-dispersive X-ray (EDX) elemental mapping images of FeCoNiS-FeO\textsubscript{x} are shown in Figure 3A, which demonstrate unique distribution of Fe, Co, Ni, and S elements. EDX pattern is shown in Figure 3B, which exhibits types and relative amounts of different elements based on the position and intensity of element spectral lines.
X-ray photoelectron spectroscopy (XPS) of FeCoNiS-FeOOH is shown in Figure 4, which was performed to characterize the chemical states of different elements. Figure 4A is full-scale XPS spectrum, further revealing the presences of Fe, Co, Ni, S, and O elements in the catalyst. As shown in Figure 4B, high-spin Fe$^{3+}$ of FeOOH contains unpaired electrons and therefore exhibit multiplet structures in Fe 2p$_{3/2}$ area. The characteristic peaks of Fe 2p$_{1/2}$ is at 725.8 eV. The satellite peaks (identified as “Sat.”) are at 719.3 and 732.3 eV, which are relevant to Fe 2p$_{3/2}$ and Fe 2p$_{1/2}$ of FeOOH (Biesinger et al., 2011; Zeng et al., 2012; Zhou et al., 2018). There are two peaks at 714.4 and 723.9 eV, which are relevant to Fe$_3$O$_4$. In Figure 4C, there exhibit two spin-orbit doublets. The first doublet is at 778.6 and 793.5 eV, assigned to Co 2p$_{3/2}$ and Co 2p$_{1/2}$ of Co$^{3+}$, and the second doublet was at 781.9 and 797.8 eV, arising from Co 2p$_{3/2}$ and Co 2p$_{1/2}$ of Co$^{2+}$. In addition, two broad peaks located at 803.6 and 786.7 eV are attributed to the satellites, which indicated the presence of Co$_3$S$_4$ (Xiao et al., 2014; Liu et al., 2015; Gao et al., 2018; Wang X. et al., 2018).

In the Ni 2p spectrum (Figure 4D), there exist two main peaks at 855.7 and 873.5 eV assignable, respectively to Ni 2p$_{3/2}$ and Ni 2p$_{1/2}$ spin orbit doublets and two satellite peaks (862.4 and 880.1 eV). By deconvolution of the two main peaks, the Ni 2p$_{3/2}$ orbit comprises two peaks with binding energy of 853.6 and 856.7 eV, which corresponded, respectively to the Ni$^{2+}$ and Ni$^{3+}$ oxidation states, and the Ni 2p$_{1/2}$ orbit can also be fitted into two peaks belonging to Ni$^{2+}$ (871.5 eV) and Ni$^{3+}$ (875.2 eV) (Hu et al., 2015; Qin et al., 2016; Sivanantham et al., 2016). There show S 2p$_{3/2}$ and S 2p$_{1/2}$ peaks at 161.7 and 162.8 eV in Figure 4E, which can be attributed to S$^{2-}$ (Wang H. et al., 2018). The component peak at 164.1 eV is characteristics of a metal–sulfur (M-S) bond (Ning et al., 2018). The peaks of 168.9 and 170.1 eV can be attributed to SO$_4^{2-}$ due to air oxidation (Cheng et al., 2015). In the O 1s region (Figure 4F), the peaks of 530.0, 531.9, and 533.8 eV are observed on the surface of the catalyst, which are corresponding to O$^{2-}$, hydroxyl group, and adsorbed water molecules, respectively (Luo et al., 2017).

The catalysis performance of the catalyst in water oxidation reaction is evaluated by linear sweep voltammetry (LSV), shown in Figure 5A. For comparison, LSV curves of different catalysts with similar loading amounts, including CC, RuO$_2$, FeCoNi-FeOOH, FeCoNi-FeO$_x$, FeCoNiS-FeO$_x$, are also evaluated. Overpotentials in the same current density are often used to estimate the OER performance. FeCoNiS-FeOOH/CC exhibits outstanding OER performance with driving 100 mA cm$^{-2}$ at a low overpotential of 269.9 mV, which is superior to RuO$_2$/CC and FeCoNi-FeO$_x$ under the same conditions. FeCoNi-FeO$_x$ is prepared through second hydrothermal method without sulfurizing reagent. The OER activity of FeCoNi-$\text{FeO}_x$ is lower than FeCoNi-FeOOH. The existence of Fe$_3$O$_4$ will not enhance catalytic reactivity. The main active site of FeCoNiS-FeO$_x$ is FeCoNi sulfides. Tafel plots of different OER catalysts were shown in Figure 5B, which are used to evaluate the catalytic kinetics. The Tafel slope of FeCoNiS-FeO$_x$ is 45.1 mV dec$^{-1}$, lower than
that of RuO$_2$/CC (52.3 mV dec$^{-1}$). It demonstrates that the FeCoNiS-FeO$_x$ catalyst has more rapid reaction velocity in OER catalytic reaction.

Another important performance, stability of catalyst, is investigated by cyclic voltammetry and potentiostatic method. As shown in Figure 5C, there shows a comparison of two polarization curves, including original curve and another curve after 500 CV cycles. When the potential is 1.5 V, the current density is only 3% decrease after 500 cycles, which demonstrates that the FeCoNiS-FeO$_x$ catalyst has a good cycle life. In Figure 5D, the electrochemical stability of FeCoNiS-FeOOH/CC is tested by potentiostatic electrolysis at a constant potential of 1.48 V for 30 h. There is only 5% decay of current density, which demonstrated the good long-term durability of the catalyst. Multistep chronopotentiometric curve of FeCoNiS-FeO$_x$ is shown in Figure 6. There are 12 steps and the increment of current density is 20 mA cm$^{-2}$ per 500 s. In every step, the corresponding potential remains constant. These results indicate that the catalyst has excellent conductivity and good mass transportation.

**CONCLUSIONS**

In this paper, a two-step hydrothermal routine is adopted to prepare FeCoNiS-FeO$_x$ catalyst. At first, hydroxide nanowire array precursor is prepared. The precursor nanowire arrays serve as backbones for the catalyst not only constructs effective conductive channels but also provides rich active sites. Secondly, the final product is prepared via anion exchange and redox reactions with Na$_2$S as sulfurizing reagent. The catalyst shows excellent OER activity needing overpotentials of 220.5 and 269.9 mV to attain current densities of 10 and 100 mA cm$^{-2}$ in 1.0 M KOH. Typically, the catalyst also shows long-term electrochemical stability for at least 30 h. The good catalysis performance is due to FeS, Co$_3$S$_4$, and Ni$_3$S$_4$. CC as substrate could enhance the conductivity of the material. Nanowire structure could increase the surface area of materials and expose more active sites. Most importantly, transition-metal sulfide could optimize material structure and give a full play to the synergy effect between different elements. FeCoNiS-FeO$_x$ catalyst is a promising electrocatalyst for OER in alkaline media.
MATERIALS AND METHODS

Materials
Ferric nitrate $[\text{Fe(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}, \text{Mw} = 404.00]$, nickel nitrate $[\text{Ni(NO}_3\text{)}_2\cdot6\text{H}_2\text{O}, \text{Mw} = 291.03]$, cobalt nitrate $[\text{Co(NO}_3\text{)}_2\cdot6\text{H}_2\text{O}, \text{Mw} = 290.79]$, ammonium fluoride $\text{NH}_4\text{F}, \text{Mw} = 37.0$, urea $[\text{CO(NH}_2\text{)}_2\cdot0.12\text{g}]$ are added to 20 ml ultrapure water to form mixture solution after 30 min stirring. The final solution and the pretreated CC are sealed in a 30-ml Teflon-lined stainless-steel high-pressure reactor and maintained at 120°C for 5 h. Then, the product is naturally cooled to room temperature. The product is taken from the reactor and washed for three times with ultrapure water and ethanol successively. Dried under 60°C for 2 h.

Preparation of Precursor
Fe(NO$_3$)$_3$·9H$_2$O 0.323 g, Ni(NO$_3$)$_2$·6H$_2$O 0.058 g, Co(NO$_3$)$_2$·6H$_2$O 0.058 g, NH$_4$F 0.03 g, CO(NH$_2$)$_2$ 0.12 g are added to 20 ml ultrapure water to form mixture solution after 30 min stirring. The final solution and the pretreated CC are sealed in a 30-ml Teflon-lined stainless-steel high-pressure reactor and maintained at 120°C for 5 h. Then, the product is naturally cooled to room temperature. The product is taken from the reactor and washed for three times with ultrapure water and ethanol successively. Dried under 60°C for 2 h.

Preparation of FeCoNiS-FeO$_x$ Nanowire
First, 0.035 g sodium sulfide is added to 20 ml ultrapure water with stirring. The formed solution and the
precursor are sealed in a 30-ml Teflon-lined stainless-steel high-pressure reactor and maintain at 120°C for 3h. After naturally cooling to room temperature, the product is washed with ultrapure water and ethanol successively. At last, the product is dried for 2h under 60°C.

Characterizations
A diffractometer (Rigaku/D/MAX 2550, Cu Kα radiation, λ = 1.5418 Å) is used to perform XRD characterization. The scan range is from 5 to 80° with a scanning rate of 5°/min. SEM characterizations are realized on a MERLIN compact SEM with the accelerating voltage of 20 kV. TEM characterizations are realized on TEM of Zeiss Libra 200FE with operation voltage of 200 kV. An ESCALABMK II X-ray photoelectron spectrometer is used to measure XPS spectrum with Mg as the exciting source.

Electrochemical Measurements
A CHI 660E electrochemical analyzer (CH Instruments, Inc., Shanghai) is used to perform all the electrochemical tests. In order to better characterize the electrode reaction, a three-electrode system is adopted. The catalysts/CC is used as working electrode. Mercuric oxide electrode (Hg-HgO) is as contrast electrode. Graphite rod is as auxiliary electrode. Potassium hydroxide solution (1.0 M) is used as the working electrolyte solution. All experiments are realized at 25°C. All potentials for LSV curves are calibrated on reversible hydrogen electrode (RHE) scale [E (RHE) = E + 0.059 × 14 + 0.098]. Unless stated otherwise, all LSV potentials are calibrated with ohmic potential drop (IR) due to solution resistance. Overpotentials (ΔE) are calculated based on the equation ΔE = E (RHE) - IR - 1.23.
