Abstract - Novel and innovative materials for biomedical and pharmaceutical applications have to consider several factors during their fabrication, such as the material composition and thermal stability, aiming to establish the promising physicochemical properties towards efficient and controlled drug release systems. In this study, carboxymethyl cellulose (CMC) hydrogels are prepared by incorporating silica dioxide (SiO2) nanoparticles previously modified with primary amine (−NH2) functional groups, aiming to evaluate the chemical composition and to improve the thermal efficiency. The carbodiimide chemistry method is performed to promote the crosslinking of the CMC structure through the formation of amide bonds from the activation of carboxyl (C=O) groups and further covalent binding with -NH2 groups. The morphology information displays high dispersed SiO2 nanoparticles with a smooth surface, regular shape, and an average particle size of 104 nm. The material composition and thermal stability are evaluated using the Fourier transform infrared spectroscopy and thermogravimetric analysis to establish a preliminary overview of a functional hydrogel for biomedical and pharmaceutical applications. The formation of amide bonds is confirmed indicating the successful crosslinking of the CMC structure with SiO2-NH2 nanoparticles, which is attributed to the activation of the C=O groups and its strong affinity to the -NH2 groups. This interaction enhanced the thermal stability of the crosslinked CMC-SiO2 hydrogels up to 469°C which was the last decomposition event, outstanding the contribution of major content of SiO2-NH2 nanoparticles. These results suggest a suitable procedure for the fabrication of crosslinked CMC-SiO2 hydrogels as novel materials with promising physicochemical properties, which can contribute to the biomedical and pharmaceutical fields in controlled drug release and delivery systems.

FABRICACIÓN DE HIDROGELES ENTRECruzados DE CARBOXIMETIL CELULOSA-SiO2: COMPOSICIÓN Y ESTABILIDAD TÉRMICA HACIA APLICACIONES BIOMÉDICAS

Resumen - Nuevos e innovadores materiales para aplicaciones biomédicas y farmacéuticas deben considerar factores como la composición y la estabilidad térmica para establecer las propiedades fisicoquímicas adecuadas para sistemas eficientes de liberación controlada de fármacos. En este estudio, hidrogeles de carboximetilcelulosa (CMC) son preparados incorporando nanopartículas de dióxido de silice (SiO2) previamente modificadas con grupos de aminas primarias (-NH2), buscando evaluar...
la composición química y mejorar la estabilidad térmica. El método de carbodiimidas es utilizado para promover el entrecruzamiento de la CMC con la formación de enlaces amidas a partir grupos carboxilo (C=O) activados y su posterior enlace con grupos -NH2. La información morfológica muestra nanopartículas de SiO2 dispersas con superficie lisa, forma regular, y diámetro promedio de 104 nm. La composición del material y la estabilidad térmica son evaluadas usando la espectroscopía infrarroja de la transformada de Fourier y el análisis termogravimétrico para establecer una perspectiva preliminar de hidrogeles funcionales para aplicaciones biomédicas y farmacéuticas. La formación de enlaces amidas es confirmado indicando el entrecruzamiento exitoso de la estructura de la CMC con nanopartículas de SiO2-NH2, el cual es atribuido a la activación de los grupos C=O y su fuerte afinidad a los grupos -NH2. Esta interacción mejoró la estabilidad térmica de los hidrogeles entrecruzados de CMC-SiO2 hasta 469°C la cual fue el último evento de descomposición, resaltando la contribución de una mayor presencia de nanopartículas de SiO2-NH2. Estos resultados sugieren un adecuado proceso de fabricación de hidrogeles entrecruzados de CMC-SiO2 como material novedoso con propiedades fisicoquímicas prometedoras, permitiendo contribuir en el campo biomédico y farmacéutico en sistemas de administración controlada de fármacos.

**Introduction**

In recent years, nanotechnology has been focusing on the development of innovative nanomaterials with exceptional physicochemical properties for a wide number of applications, outstanding the biomedicine and pharmaceutical fields (Tang et al., 2020). Among these nanomaterials, the silica dioxide (SiO2) nanoparticles are extensively explored due to the advantages offered by their biocompatibility, chemical, and enzymatic stability, reactive surface area, environmentally friendly, and good cost-effectiveness (Abeer et al., 2020). The SiO2 nanoparticles are synthesized through different physical and chemical methods, which is highlighted the Stöber method due to its simplicity and effectiveness. However, the presence of silanol (Si-OH) groups on the surface after the synthesis represent a challenge, reducing the advantages of using this type of nanoparticles (Sepulveda et al., 2020). This can be solved by functionalizing the surface of the SiO2 nanoparticles using different functional groups, such as primary amines (NH2), allowing also to increase the selectivity and affinity (Mahmoodi, Khorramfar, & Najafi, 2011).

Also, biopolymers are being studied along with the nanomaterials for developing and designing different drug delivery systems, in which the combination provides superior characteristics, such as non-toxicity, biodegradability, and high loading cargo and sustained release (Gholamali & Yadollahi, 2020). Carboxymethyl cellulose (CMC) is a promising example of these explored biopolymers and has proven to be efficient in therapeutic systems for biomedical and pharmaceutical applications (Rao et al., 2018). These CMC biopolymers have been explored in industries and academia for their promising physicochemical properties, including hydrophilicity, non-toxicity, and pH-sensitivity (Javanbakht & Shaabani, 2019). The ability to hydrogel-forming using CMC is mainly attributed to the ionic nature and a large amount of carboxyl (C=O) and hydroxyl (–OH) groups in the structure (Jeong, Kim, Kim, & Jung, 2020). However, a few but important limitations, such as the mechanical, thermal, and chemical stability, need to be addressed in the CMC hydrogels to compete with synthetic and non-biodegradable polymers (Shahbazi, Ahmadi, Seif, & Rajabzadeh, 2016).
Crosslinked carboxymethyl cellulose-SiO2 hydrogels fabrication: Composition and thermal stability towards biomedical applications

Physical, chemical (Lin et al., 2020), and enzymatic crosslinking methods arose to overcome the mentioned limitation in the CMC hydrogels formation, improving their physicochemical properties (Zhong et al., 2019). Among the crosslinking agents, citric acid, polyacrylamide, antibacterial Propolis honey, polyethylene glycol (Kanikireddy, Varaprasad, Jayaramudu, Karthikeyan & Sadiku, 2020), glutaraldehyde, formaldehyde, carbodiimide (Jiang et al., 2016), calcium, and aluminum have been widely explored (Mahmoud, Abdou, Sobhy & Fekry, 2017). Although the crosslinking of CMC hydrogel represents a good alternative, there are still challenges regarding the biocompatibility (Jiang et al., 2016), swelling (Jeong et al., 2020), and drug release (Kadry, 2019), which reports suggest their decreasing when using crosslinking agents. Carbodiimide crosslinker chemistry has been reported to be suitable for the hydrogel formation through the covalent binding between NH2 and C=O groups, resulting in an amide crosslinked bonds in the polymer's structure, including poly (dimethylsiloxane) (Mapkar, Iyer, & Coleman, 2009), and β-cyclodextrin (Tang et al., 2020).

This study reports the synthesis of SiO2 nanoparticles using the Stöber method, and the surface modification with primary -NH2 functional groups. These SiO2-NH2 nanoparticles were used for the first time, during the formation of CMC hydrogels via the carbodiimide crosslinker chemistry method. This study aims to evaluate the chemical composition and thermal stability of the resulting CMC hydrogels compared to similarly reported CMC hydrogels using other crosslinking agents. In this method, amides bonds were formed from the activation of C=O groups in the CMC structure and the further binding with -NH2 groups grafter on the surface of the SiO2 nanoparticles. The material composition was corroborated using the Fourier transform infrared (FTIR) spectroscopy, allowing to identify the successful formation of amide bonds. Whereas the thermogravimetric analysis (TGA) confirmed the high thermal stability due to the presence of uniform and spherical SiO2 nanoparticles. These results are promising for the preparation of crosslinked CMC-SiO2 hydrogels with enhanced physicochemical properties, aiming to contribute with a suitable biomaterial for applications in the biomedicine and pharmaceutical fields as an efficient and controlled drug release system.

**Experimental Methods**

**Materials**

Carboxymethyl cellulose sodium salt (CMC), tetraethyl orthosilicate (TEOS, 98%), dimethyl sulfoxide (DMSO, 99%), and (3-Aminopropyl)triethoxysilane (APTES, 98%) were acquired from Alfa Aesar by Thermo Fisher Scientific. Ammonium hydroxide (NH4OH, 30%) and absolute ethanol were purchased from Merck. 1-Ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC), N-Hydroxysuccimide (NHS, 98%), acetic acid (99%), and nitric acid (HNO3, 70%) were acquired from Sigma-Aldrich. Distilled water and deionized water were used in all the experiments.

**Synthesis of SiO2 nanoparticles**

The SiO2 nanoparticles were synthesized via the Stöber method consisted of the hydrolysis/condensation using the TEOS precursor (Sepulveda et al., 2020). Initially, 1.1 mL of TEOS was added into 50 mL of absolute ethanol followed by sonication at room temperature for 10 min. Afterward, the hydrolysis of TEOS was carried out by adding 1.53 mL of distilled water dropwise into the previous solution and left to react for 5 min in the ultrasound bath at room temperature. The condensation and further nucleation were
promoted using 5.71 mL of NH₄OH as the catalyst, allowing to react for another 15 min at the same operating conditions. After completing the reaction time, the solution was taken out of the ultrasound and left for solidification during 1 h, consisting of the stable growth of the colloids. The resulting SiO₂ nanoparticles were collected by centrifugation at 15000 g-force and room temperature for 15 min and then washed with distilled water and absolute ethanol to eliminate remaining TEOS and other impurities. Finally, the SiO₂ nanoparticles were dried in a conventional oven at 70°C for 2 h.

**Amine functionalization of SiO₂ nanoparticles**

The surface of the SiO₂ nanoparticles was modified by grafting amine (-NH₂) functional groups from APTES molecules (Z. Zhang et al., 2018). Here, 1.5 g of SiO₂ nanoparticles were suspended in 80 mL of DMSO using an ultrasound bath and then vigorous stirring. Afterward, 5 mL of APTES, 1.25 mL of distilled water, and 0.1 mL of acetic acid were added dropwise and the solution was left to react for 72 h at room temperature. The SiO₂-NH₂ nanoparticles were separated from the solution centrifuging at 15000 g-force and room temperature for 15 min followed by washes with distilled water and ethanol. Then, 0.1 or 0.5 g of the as-synthesized SiO₂-NH₂ nanoparticles were dispersed in 10 mL of deionized water using an ultrasound bath for 15 min and the pH was adjusted to 4 adding drops of a 2 M HNO₃ solution. The suspension was stored at 4°C for further crosslinking with CMC.

**Preparation of crosslinked CMC-SiO₂ hydrogel**

The crosslinked CMC-SiO₂ hydrogel was prepared through carbodiimide crosslinker chemistry between carboxylic acid and primary amine functional groups (Tang et al., 2020). Initially, the hydrogel was prepared by adding 0.1 g of CMC sodium salt in 7.5 mL of deionized water under 125 rpm of stirring at room temperature. Once the solution is homogenized, the pH was adjusted to 5 using drops of a 0.1 M NaOH solution. Then, the carboxyl groups of the CMC sodium salt were activated adding 12.5 mg of EDC and 7.5 mg of NHS, keeping the same operating conditions. Afterward, the formation of amide bonds was performed adding the SiO₂-NH₂ nanoparticles suspension into the previous hydrogel solution, which was left to react at 125 rpm and room temperature for 48 h. Finally, the crosslinked CMC-SiO₂ hydrogel was dried using an electric oven at 38°C for 7 h.

**Characterizations**

The morphology of the CMC and SiO₂ nanoparticles was investigated using a scanning electron microscope (SEM) QUANTA FEG 650 with an acceleration voltage of 7 kV. The identification of the functional groups and the crosslinked structure was performed using the Fourier transform infrared (FTIR) spectroscopy in an IR Affinity Shimadzu S/N A213749 equipment. The KBr dispersion method was used in a wave number range between 4000 and 400 cm⁻¹ at room temperature for 10 min. The thermogravimetric analysis (TGA) and derivative thermogravimetric (DTG) curve were performed in a TA Instruments SDT Q600 using a 100 mL/min airflow in the temperature range of 26 and 600°C with a heating ramp of 10°C/min.
Results and Discussion

The scanning electronic microscopy (SEM) was used to evaluate the morphology information of the assynthesized SiO2 nanoparticles. According to Figure 1, the SiO2 nanoparticles exhibit a regular smooth surface and sphere shape, which is attributed to the controlled hydrolysis/condensation procedure of TEOS precursor. Although some nanoparticles possess irregular shape, it can be stated that the SiO2 nanoparticles are regular with an average particle size of 104 ± 12 nm as seen in Figure 2. Here, the solidification stage during SiO2 nanoparticles synthesis plays an important role since it allows controlling the particle size, and it has been reported that the longer is the solidification stage the larger is the particle size. Additionally, no agglomeration was noted in the SEM image allowing the confirm the high dispersion of the SiO2 nanoparticles. This is mainly attributed to the in-situ surface functionalization of the SiO2 nanoparticles with hydroxyl (-OH) groups during the condensation of the silica matrix, which is typical for this nucleation method. The high dispersion of SiO2 nanoparticles represents a suitable feature when applying in the biomedicine field, which is used as nanoplatforms to bind different molecules for cell targeting (Giner-Casares, Henriksen-Lacey, Coronado-Puchau, & Liz-Marzán, 2016), and drug delivery (Lee et al., 2020).

Figure 1. SEM image of SiO2 nanoparticles synthesized via the Stöber method
The main functional groups of the crosslinked CMC-SiO₂ hydrogels were determined in the Fourier transform infrared (FTIR) spectra shown in **Figure 3**. Here, hydroxyl, carboxyl, and amine functional groups were identified after performing the carbodiimide crosslinker chemistry and using EDC and NHS. The intense and broadband between 3700 and 2500 cm⁻¹ corresponds to the stretching vibrations of -OH groups. This broadband appeared due to the large number of -OH groups composing the CMC structure, which was highlighted a specifically centered peak around 3000 cm⁻¹ ascribed to the carboxylic acid content (Zhu, Bao, Wei, Ma, & Kong, 2016). In addition to this peak, high intensity but sharper peak located between 1440 and 1395 cm⁻¹ was also related to the presence of the carboxylic acid content widely available in the CMC structure. A strong peak was noted at around 1640 cm⁻¹ attributed to the presence of C=O (Kamel, El-Gendy, Hassan, El-Sakhawy, & Kelnar, 2020), and -NH bonds from the secondary amides (Rao et al., 2018), that were formed during the carbodiimide crosslinker chemistry (see **Figure 4**).
In this process, the EDC allowed the formation of intermediates with the carboxyl groups in the CMC structure, such as the O-acylisourea (see Figure 4a), which is an unstable molecule. Then, the NHS was used to activate the carboxyl groups linked to the EDC molecules by displacing the O-acylisourea as isourea, promoting the formation of amine-reactive NHS ester (see Figure 4b) as another intermediate but more stable molecule. The activated carboxyl group was then able to interact with the primary amine group grafted on the surface of the SiO₂ nanoparticles, completing the crosslinking of the CMC structure through the formation of secondary amides (see Figure 4c). Therefore, the successful crosslinking of CMC with the SiO₂ nanoparticles was confirmed with the peak around 1640 cm⁻¹, along with another one located between 1250 and 1020 cm⁻¹ ascribed to C-N stretching vibrations (Asere et al., 2019).

On the other hand, the representative peaks of the SiO₂ nanoparticles are evidenced in the wavenumber region of 1100 and 400 cm⁻¹, which is attributed to the silanol (Si-OH) and siloxane (Si-O-Si) functional groups. The peaks around at 1069 and 687 cm⁻¹ corresponded to the asymmetric and symmetric Si-O bonds for the SiO₂ structure (Pourrajab, Noghrehabadi, Hajidayalloo, & Behbahani, 2020), whereas the medium intensity and broadband between 650 and 450 cm⁻¹ were attributed to the bending Si-O-Si vibration (Asri Mohd Esa & Sapawe, 2020). An addition band was noted in the wavenumber region from 966 to 819 cm⁻¹, which indicates remaining Si-OH groups available on the large surface area of the SiO₂-NH₂ nanoparticles (Pourrajab et al., 2020). This represents a suitable surface for enhanced grafting with NH₂ groups, providing a major crosslinking area for the interaction and binding with the carboxyl group from the CMC structure.
The thermogravimetric analysis (TGA) and derivative thermogravimetric (DTG) curves are displayed in Figure 5 and Figure 6. The CMC was crosslinked using different concentrations of SiO2-NH2 nanoparticles to evaluate the thermal stability, considering as an important factor for applications in the biomedicine field. In Figure 5, the crosslinked CMC-SiO2 hydrogel using 0.1 g of SiO2-NH2 nanoparticles exhibited two main weight loss stages with several thermal events and maximum decomposition peaks. The three first event at 53, 102, and 164°C were mainly attributed to moisture or some water content in the crosslinked CMC-SiO2 hydrogel with a weight loss of about 27%, in which water is evaporated at 164°C due to the strong binding between the CMC and SiO2-NH2 nanoparticles. Afterward, the weight was reduced up to 33% with a maximum decomposition at 250 and 279°C attributed to the release of CO2 from the carboxyl groups contained in the cellulose backbone(Jiang et al., 2016), which promote the cleavage and fragmentation of the main bonds in the structure(C. Zhang et al., 2020). However, two more events occurred at 352 and 430°C,suggesting the decomposition of more stable organic content, which is related to the presence of SiO2-NH2 nanoparticles that provides higher thermal stability.
Crosslinked carboxymethyl cellulose-SiO2 hydrogels fabrication: Composition and thermal stability towards biomedical applications

Figure 5. Thermogravimetric analysis (TGA) and derivative thermogravimetric (DTG) curve of the hydrogels crosslinked with 0.1 g of SiO2-NH2 nanoparticles to determine changes in the sample weight over time as the temperature increases.

In the case of the hydrogels crosslinked with 0.5 g of SiO2-NH2 nanoparticles shown in Figure 6, a two-stage thermal decomposition was also observed. The decomposition events are reduced attribute to the presence of SiO2-NH2 nanoparticles, in which the evaporation of water content occurred up to 107°C instead of 164°C since the availability of -OH decreased due to the interaction with primary -NH groups. However, the weight loss was around 37% in this first stage, which was 10% more compared to the crosslinked CMC-SiO2 hydrogel using 0.1 g of SiO2-NH2 nanoparticles. This effect is attributed to a major content of water that was adsorbed on the surface of the SiO2-NH2 nanoparticles, considering that the concentration was increased to 0.5 g which promotes a larger available surface area. In the second stage, the total number of decomposition events decreased, as well as the decomposition area, indicating major thermal stability in the crosslinked CMC-SiO2 hydrogel structure. This is observed from the total remaining weight of 56% at 485°C, in which the last thermal event 469°C related to the decomposition of more stable organic content, suggests an enhancement of about 30°C concerning the crosslinked hydrogels using 0.1 g of SiO2-NH2 nanoparticles. These two-stages decomposition results are highlighted in comparison with others studies in the literature for crosslinked CMC hydrogels using complex crosslinking agents, such as polyacrylamide (Jeong et al., 2020), ZnO nanoparticles (Gholamali & Yadollahi, 2020), and TiO2 nanoparticles (Mahmoud et al., 2017) with a total remaining weight around 21, 30, and 60%, respectively. Accordingly, the formation of amide covalent bonds using the carbodiimide crosslinker chemistry between the carboxylic acid from the CMC and the primary amine functional groups from the SiO2-NH2 nanoparticles, represent a more efficient alternative for the fabrication of hydrogels by increasing the thermal stability up to 35%.
Conclusions

This study reported the synthesis and amine-functionalization of SiO2 nanoparticles for the incorporation in crosslinked CMC hydrogels via the carbodiimide crosslinker chemistry. The material composition and thermal stability were deeply evaluated and analyzed, aiming to establish the potential application of the crosslinked CMC-SiO2 hydrogels in controlled drug release and delivery systems. The primary NH2 groups grated on the surface of the SiO2 nanoparticles provided high affinity and strong interaction with the activated C=O groups from the carboxylic acid in the CMC structure. This allowed the formation of stable amide bonds, which promoted enhanced thermal stability when increasing the temperature, as was observed in the DTG curves. Moreover, the content of SiO2-NH2 nanoparticles played an important role in the thermal stability of the CMC hydrogels, decreasing the percentage of decomposition and reducing the number of thermal events. According to these results, the crosslinked CMC-SiO2 hydrogels showed to be a promising material compared to similar reported in the literature with lower thermal efficiencies.

Additional future research work involves a profound determination of the physicochemical properties, including chemical stability, drug loading and release capacities, swelling percentage, and the influence of...
Crosslinked carboxymethyl cellulose-SiO₂ hydrogels fabrication: Composition and thermal stability towards biomedical applications

parameters such as pH, temperature, and enzyme content on the efficiency of the controlled drug release systems.

Sepulveda, J., Villegas, C., Torres, A., Vargas, E., Rodriguez, F., Baltazar, S., … Galotto, M. J. (2020). Effect of functionalized silica nanoparticles on the mass transfer process in active PLA nanocomposite films obtained by supercritical impregnation for sustainable food packaging. *Journal of Supercritical Fluids, 161*(July), 104844. [https://doi.org/10.1016/j.supflu.2020.104844](https://doi.org/10.1016/j.supflu.2020.104844)

Shahbazi, M., Ahmadi, S. J., Seif, A., & Rajabzadeh, G. (2016). Carboxymethyl cellulose film modification through surface photo-crosslinking and chemical crosslinking for food packaging applications. *Food Hydrocolloids, 61*(December), 378–389. [https://doi.org/10.1016/j.foodhyd.2016.04.021](https://doi.org/10.1016/j.foodhyd.2016.04.021)

Tang, J., Li, Y., Song, Y., Wu, X., Yu, G., & Tam, K. C. (2020). Carbodiimide coupling versus click chemistry for nanoparticle surface functionalization: A comparative study for the encapsulation of sodium cholate by cellulose nanocrystals modified with β-cyclodextrin. *Carbohydrate Polymers, 244*(May), 116512. [https://doi.org/10.1016/j.carbpol.2020.116512](https://doi.org/10.1016/j.carbpol.2020.116512)

Zhang, C., Yang, X., Li, Y., Qiao, C., Wang, S., Wang, X., … Li, T. (2020). Enhancement of a zwitterionic chitosan derivative on mechanical properties and antibacterial activity of carboxymethyl cellulose-based films. *International Journal of Biological Macromolecules, 159*(September), 1197–1205. [https://doi.org/10.1016/j.ijbiomac.2020.05.080](https://doi.org/10.1016/j.ijbiomac.2020.05.080)

Zhang, Z., Zhu, Y., Dai, R., Zhang, Y., Wang, H., & Li, J. (2018). Enhanced photocytotoxicity induced by a platinum diimine complex employing amine-functionalized magnetite-silica nanocomposites as delivery vehicles. *Photodiagnosis and Photodynamic Therapy, 23*(June), 50–54. [https://doi.org/10.1016/j.pdpdt.2018.06.002](https://doi.org/10.1016/j.pdpdt.2018.06.002)

Zhong, Y., Wang, J., Yuan, Z., Wang, Y., Xi, Z., Li, L., … Guo, X. (2019). A mussel-inspired carboxymethyl cellulose hydrogel with enhanced adhesiveness through enzymatic crosslinking. *Colloids and Surfaces B: Biointerfaces, 179*(December 2018), 462–469. [https://doi.org/10.1016/j.colsurfb.2019.03.044](https://doi.org/10.1016/j.colsurfb.2019.03.044)
Crosslinked carboxymethyl cellulose-SiO2 hydrogels fabrication: Composition and thermal stability towards biomedical applications

Zhu, X., Bao, L., Wei, Y., Ma, J., & Kong, Y. (2016). Removal of toxic indigo blue with integrated biomaterials of sodium carboxymethyl cellulose and chitosan. International Journal of Biological Macromolecules, 91(October), 409–415. https://doi.org/10.1016/j.ijbiomac.2016.05.097
