Abstract
Background: Laparoscopic one anastomosis gastric bypass has become a prominent bariatric procedure. Yet, early and late complications, primarily leaks and strictures, are not uncommon. This study summarizes our experience with endoscopic treatment of laparoscopic one anastomosis gastric bypass complications.

Methods: This is a retrospective study of consecutive patients referred to our hospital from 2015 to 2017 with post laparoscopic one anastomosis gastric bypass complications. Therapy was tailored to each case, including fully covered self-expandable metal stents, fibrin glue, septotomy, internal drainage with pigtail stents, through-the-scope and pneumatic dilation. Success was defined as resuming oral nutrition without enteral or parenteral support or further surgical intervention.

Results: Nine patients presented with acute or early leaks: 5 (55.6%) had staple-line leaks, 3 (33.3%) had anastomotic leaks and 1 (11.1%) had both. All were treated with stents. Adjunctive endoscopic drainage was applied in 4 patients (44.4%). Overall 5 patients (55.6%) with acute/early leaks recovered completely, including all 3 patients with anastomotic leak and the patient with both leaks but only 1/5 with staple line leak (20%). Complication rate in the leak group reached 22.2%. Eight patients presented with strictures, 7 at the anastomosis and one due to remnant stomach misalignment. All anastomotic strictures were dilated successfully. However, the patient with the pouch stricture required conversion to Roux-en-Y gastric bypass after 3 failed attempts of dilatation.

Conclusion: Endoscopic treatments of laparoscopic one anastomosis gastric bypass complications are relatively effective and safe. Anastomosis-related complications are more amenable to endoscopic treatment compared to staple line leaks.

Background
Morbid obesity has become a major global health threat that leads to severe morbidity including diabetes, hypertension, obstructive sleep apnea and cardiovascular diseases. To date, bariatric surgery is the most effective intervention for weight reduction and remission of associated comorbidities [1]. Laparoscopic one anastomosis gastric bypass (LOAGB), introduced in 1997 [2], is gaining popularity and has become the fourth most performed surgery in Europe and the Asia/Pacific
Results with LOAGB in terms of weight loss and resolution of comorbidities have been promising [4–6]. Still, early and late complications occur at an estimated rate of 3.1% and 10% respectively [7]. Potential adverse events include postoperative or chronic leaks and strictures. Endoscopic management of postoperative leaks is challenging and constantly evolving with no clear guidelines. The aim of endoscopic treatment is to divert gut secretion away from the leak site to allow fistula healing and resuming oral nutrition as early as possible. These goals may be achieved by deploying fully covered self-expanding metal stents (FC-SEMS) [8–13]. Other strategies including over the scope clips (OTSC), fibrin glue, endoscopic suturing and intragastric drainage (IGD) with double pigtail stent (DPS) have been all described with variable success rate [9, 14–17]. In cases of chronic leak with perigastric collection formation, a typical complication of laparoscopic sleeve gastrectomy (LSG), the preferred (an effective) endoscopic approach is to enable adequate drainage of the perigastric collection into the stomach by dissecting the septum separating the two cavities (septotomy), and to reduce the intragastric pressure by realignment of the sleeve axis using pneumatic balloon dilatation [18]. Post-surgical strictures are treated with endoscopic dilatation. While anastomotic strictures are amenable to through the scope (TTS) dilation with high success rates [19, 20], post LSG strictures due sleeve misalignment are more difficult to treat. In these cases pneumatic dilatation is preferred [21]. The aim of this study was to summarize our experience in treating post LOAGB complications amenable to endoscopic treatment, namely leaks and strictures.

Methods
This was a retrospective study of consecutive patients referred to our department with post LOAGB leaks or strictures between August 2015 and October 2017. The diagnosis was based upon symptoms, imaging and endoscopic studies. Patients were managed by a multidisciplinary team that included bariatric surgeons, gastroenterologists from the bariatric endoscopy service, invasive radiologists and nutritionists.

Postoperative leaks:
In all cases fully covered stents (Esophageal Mega stent, length 23 mm, diameter 24 mm, Teawoong, Seoul, Korea) were introduced over a stiff guidewire (38-inch Amplatz Super Stiff, Boston Scientific,
Marlborough, Mass, USA) with fluoroscopic guidance, under conscious sedation. The proximal third of the stent was located above the gastroesophageal junction and the distal end at the efferent limb. Confirmatory fluoroscopy was performed 1 day after the procedure, after which patients gradually resumed a soft oral diet. Our target duration of treatment was 2–6 weeks and was individualized by drainage output, the nature of the fluid and patient tolerability. In cases where the leak evolved to a late or chronic form (>6 or 12 weeks, respectively), internal drainage was achieved by septotomy (see Introduction) or pigtail insertion into the collection cavity. Septotomy was performed by dissecting the septum with argon plasma coagulation (Erbe Vio 200 D; forced coagulation, 70 W, 2 L/min) along the staple-line towards the base of the perigastric cavity, which was endoscopically identified. Importantly, the dissections never exceeded the base of the cavity. As a precaution, the dissections were performed gradually, with a maximal incision depth of 5–10 mm during each session. Patients resumed an oral liquid diet once adequate intragastric drainage had been achieved. DPSs with a diameter of 7 Fr and length of 7 cm (Cook Medical) were inserted under fluoroscopy into persistent residual sinuses. All procedures were performed using CO2 insufflation (Figure 1).

Postoperative strictures:

All patients were treated with balloon dilatations. Anastomotic strictures were treated with TTS balloon dilatation (CRE™ Balloon Dilatation Catheters; Boston Scientific, Natick, MA, USA). The balloon was gradually inflated up to maximal diameter of 20 mm (Figure 2). The procedure was repeated as needed. Remnant stomach misalignment resulting in mid gastric kink was treated with pneumatic balloon dilatation (Rigiflex II balloon; Boston Scientific, Natick, MA, USA). The procedure was performed under direct vision and fluoroscopy with continuous inflation up to a maximal diameter of 30 mm and pressure of 20 PSI in each session. The balloon was held maximally inflated within the stricture for 1 minute. When two consecutive procedures did not alleviate the symptoms the patient was referred to surgery.

Success was defined as resuming oral nutrition without enteral or parenteral support or further surgical intervention.

Results
Seventeen patients were referred to our clinic, 9 with postoperative leaks and 8 with postoperative strictures.

**Postoperative leak group:**

Nine patients were included in this group, 5/9 male, with a mean age of 40.7±10.8 and pre-operative mean body mass index (BMI) of 43.7±8.2 (kg/m²). Interestingly, six patients (66.7%) had revisions from previous bariatric surgery, 3 of which had two previous operations (Table 1). All cases were diagnosed by computer tomography. Endoscopic management applied in each patient and outcomes are depicted in table 2. Eight patients (88.9%) had an early leak (1–6 week) and one had an (11.1%) acute leak (<1 week). Five patients (55.6%) presented with a proximal staple-line leak (at the angle of His), 3 (33.3%) with an anastomotic leak and 1 (11.1%) with leaks at both sites. Median time between surgery and first endoscopy was 12 days (IQR 10–19) and the median number of therapeutic endoscopic sessions was 3 (IQR 2–6). All patients were treated with fully covered stents for a median period of 26 days (IQR 11–30). Additional endoscopic treatment was required in 4 patients (44.5 %). Three of them needed ancillary dilation. The first needed a single TTS balloon dilation (15 mm) of an anastomotic stricture. The second needed a single pneumatic balloon (30 mm) dilation of a mid-pouch stricture. The third developed a late stricture at the esophageal gastric junction secondary to the stent placement, treated with gradual TTS dilation up to 20 mm. Two patients with staple line leak evolved to late fistula and needed additional drainage procedures including septotomy, DPS insertion and tissue glue (Table 2).

Overall, 5 of 9 patients (55.6%) were successfully treated as defined by weaning from total parenteral nutrition, resuming oral diet, removal of intra-abdominal draining tubes, and avoidance of further surgical intervention (Table 2). All 3 patients with anastomotic leak had a favorable outcome. However only 1 of 5 patients with staple line leak had a favorable outcome. Of note, the patient with both anastomotic- and staple line-leaks recovered.

Two patients were referred to Roux-en-Y- gastric bypass (RYGB) conversion. One patient needed urgent laparotomy after 2 weeks of treatment due to stent migration and ileum perforation. Interestingly, this patient did not require further treatment for his staple-line leak. The forth patient
died due to respiratory failure unrelated to the endoscopic procedure. Of note, 3 of 4 failed patients (75%) had previous bariatric surgery.

Postoperative stricture group:

Eight patients were diagnosed with stricture based upon symptoms of vomiting and excessive weight loss. All of them were female with a mean age of 49±13.7 and preoperative mean BMI of 38.7±8.7 (kg/m2). Four patients (50%) had previous bariatric surgery (Table 3). Stricture site and mode of treatment are depicted in Table 4. Seven patients (87.5%) presented with anastomotic stricture and one patient (12.5%) with a mid-pouch kink. The median time between surgery and the first endoscopic dilatation was 63 days (IQR 37–140), and the median number of therapeutic endoscopic dilatations was 3 (2–4). Anastomotic strictures were TTS-dilated with a maximal balloon diameter of 20 mm and the pouch stricture was pneumatically dilated with a balloon diameter of 30 mm. Overall success rate was 87.5%. All 7 patients with anastomotic stricture reported significant clinical improvement (Table 4). The patient with the pouch kink was defined as a treatment failure due to persistent vomiting and weight loss after 3 attempts of pneumatic dilatation and finally underwent conversion to formal RYGB surgery.

Discussion

Herein we demonstrate that endoscopic treatment of post-LOAGB leaks and strictures is effective and safe. To our knowledge this is the largest series described to date. In 10 of 17 patients a previous bariatric procedure had been performed (58.9%), which is a known risk factor for post-surgery complications [22, 23]. Interestingly, LOAGB complications may be divided into anastomosis-related stricture and leaks which resemble those of RYGB [24–26], and staple line leaks and remnant stomach axis deviation (kink) which are similar to those of LSG [27–29]. Our data show a 100% (7/7) success rate in TTS dilation of anastomotic strictures without any complications, similar to the 93%-100% success rate for post RYGB anastomotic stricture dilation [30]. Anastomotic leaks controlled with stent insertion also exhibited a favorable outcome with 100% success (3/3), perhaps slightly higher than treatment of post RYGB anastomotic leaks which ranges between 70–94% [30]. In contrast, treatment of staple line leaks exhibited a less favorable outcome with a success rate of only 20% (1/5),
compared to 65–95% in acute and early leaks after LSG [30]. Of note, two patients evolved to a late type of leak and received ancillary drainage with septotomy and DPS. Although we achieved excellent control of late and chronic leaks after LSG with this approach [18], currently it succeeded in only one patient. Another patient had remnant stomach misalignment (kink) with failure to dilate it pneumatically. The high rate of failure in treatment of staple line-related complications may be attributed to the high percent of previous bariatric procedures (60%) in these patients which may prevent an adequate intragastric pressure reduction that would allow the leak to heal [31].

The safety profile is acceptable. Overall, we had two major complications. One case of stent migration resulted in small bowel perforation which necessitated urgent laparotomy. One death occurred, however it was not related to the endoscopic procedure.

Our study has several limitations. These include a relatively small group of patients, performance at a single tertiary referral centre, and no control group in the study design.

Conclusion

Endoscopic treatment of LOAGB complications is effective and safe. Anastomosis-related complications are more amenable to endoscopic treatment compared to staple line related complications.

Abbreviations

BMI: Body mass index; DPS: double pigtail stent; IGD: intragastric drainage; FC-SEMS: fully covered self-expanding metal stents; LOAGB: Laparoscopic one anastomosis gastric bypass; LSG: laparoscopic sleeve gastrectomy; OTSC: over the scope clips; RYGB: Roux-en-Y gastric bypass; TTS: through the scope.

GEJ, Gastroesophageal junction.

* At the angle of His.

**Table 3. Patient demographics and surgical details of postoperative stricture group.**
| Patient number | Age (Years) | Gender | BMI (kg/m²) | Previous operation |
|----------------|-------------|--------|-------------|--------------------|
| 1              | 48          | Female | 36.5        | No                 |
| 2              | 63          | Female | 46          | No                 |
| 3              | 42          | Female | NA          | LSG                |
| 4              | 24          | Female | 39          | No                 |
| 5              | 60          | Female | NA          | LAGB               |
| 6              | 65          | Female | 47.5        | LSG                |
| 7              | 41          | Female | 23.3        | LSG                |
| 8              | 49          | Female | 40          | No                 |

BMI, Body mass index; CT, Computed tomography; LAGB, Laparoscopic adjustable gastric banding; LSG, Laparoscopic sleeve gastrectomy; NA, Not available.

### Table 4. Endoscopic dilatation of strictures and outcomes.

| Patient number | Stricture site | Days from surgery to first dilatation | Number of therapeutic dilatations | Type of dilatation | Maximal size of dilatation | Result |
|----------------|---------------|--------------------------------------|----------------------------------|--------------------|---------------------------|--------|
| 1              | Anastomosis   | 147                                  | 2                                | TTS                | 20 mm                     | Success|
| 2              | Anastomosis   | 50                                   | 5                                | TTS                | 18 mm                     | Success|
| 3              | Anastomosis   | 30                                   | 1                                | TTS                | 20 mm                     | Success|
| 4              | Anastomosis   | 33                                   | 3                                | TTS                | 15 mm                     | Success|
| 5              | Anastomosis   | 160                                  | 4                                | TTS                | 15 mm                     | Success|
| 6              | Anastomosis   | 117                                  | 3                                | TTS                | 20 mm                     | Success|
| 7              | Pouch         | 60                                   | 3                                | P                  | 30 mm                     | Failure|
| 8              | Anastomosis   | 66                                   | 3                                | TTS                | 18 mm                     | Success|

P, Pneumatic; TTS, through-the-scope.

Figures
Treatment of a staple-line leak. A. Treatment at the acute phase with stent deployment. B. Treatment at the late phase with pneumatic dilation of the remnant stomach. C. Septotomy performed to unify the perigastric collection and the remnant stomach cavity. D. A healed fistula.
Figure 2

Endoscopic balloon dilatation. A. Pinpoint anastomotic stricture. B. Through-the-scope balloon dilatation of anastomosis.
