CALCULATION OF THE CONSTANT FACTOR IN THE SIX-VERTEX MODEL

PAVEL BLEHER AND THOMAS BOTHNER

Abstract. In the present paper we calculate explicitly the constant factor \( C \) in the large \( N \) asymptotics of the partition function \( Z_N \) of the six-vertex model with domain wall boundary conditions on the critical line between the disordered and ferroelectric phases. On the critical line the weights \( a, b, c \) of the model are parameterized by a parameter \( \alpha > 1 \), as \( a = \frac{\alpha - 1}{2} \), \( b = \frac{\alpha + 1}{2} \), \( c = 1 \). The asymptotics of \( Z_N \) on the critical line was obtained earlier in the paper [8] of Bleher and Liechty: \( Z_N = CF^N G^N N^{1/4} (1 + O(N^{-1/2})) \), where \( F \) and \( G \) are given by explicit expressions, but the constant factor \( C > 0 \) was not known. To calculate the constant \( C \), we find, by using the Riemann-Hilbert approach, an asymptotic behavior of \( Z_N \) in the double scaling limit, as \( N \) and \( \alpha \) tend simultaneously to \( \infty \) in such a way that \( \frac{N}{\alpha^2} \to t \geq 0 \). Then we apply the Toda equation for the tau-function to find a structural form for \( C \), as a function of \( \alpha \), and we combine the structural form of \( C \) and the double scaling asymptotic behavior of \( Z_N \) to calculate \( C \).

1. Introduction and summary of results

The six-vertex model is a vertex model stated on a square lattice in \( \mathbb{Z}^2 \) with \( N^2 \) vertices. Along each edge we assign arrows obeying the ice-rule: at every vertex two arrows point in and two arrows point out. This rule admits only six possible configurations, which are depicted in Figure 1.

Key words and phrases. Six-vertex model, domain wall boundary conditions, critical line between disordered and antiferroelectric phases, asymptotic behavior of the partition function, Riemann-Hilbert problem, Deift-Zhou nonlinear steepest descent method, Toda equation.

The first author is supported in part by the National Science Foundation (NSF) Grants DMS-0969254 and DMS-1265172.
On the lattice boundary we consider the \textit{domain wall boundary conditions} (DWBC), in which all arrows on the top and bottom side of the lattice point inside the lattice and all arrows on the left and right side point outside, see Figure 2 for a possible $4 \times 4$ configuration with DWBC.

![Figure 2. An example of a possible $4 \times 4$ configuration with DWBC](image)

Corresponding to each possible vertex arrow configuration ($i$), we assign a Boltzmann weight $w_i, i = 1, \ldots, 6$ and introduce the partition function $Z_N$ as

$$Z_N = \sum_{\text{configurations}} \prod_{i=1}^{6} w_i^{n_i}$$

where $n_i$ denotes the number of vertices of type ($i$). The partition function $Z_N$ depends, by definition, on six parameters: the weights $w_i$. However, certain conservation laws (compare for instance [1, 6] or [20]) allow us to reduce the general case to the case when $w_1 = w_2 = a$, $w_3 = w = 4 = b$, and $w_5 = w_6 = c$. By using the homogeneity of the partition function with respect to $a$, $b$, and $c$, it can be further reduced to two parameters, $\frac{a}{c}$ and $\frac{b}{c}$.

The phase diagram of the model is shown in Figure 3 and it distinguishes the three phase regions: the antiferroelectric (AF) phase region, the disordered (D) phase region, and the ferroelectric (F) phase region. In these phase regions the weights $a$, $b$ and $c$ are usually parameterized in the following way:

\begin{align}
(F) \quad a &= \sinh(t - \gamma), \quad b = \sinh(t + \gamma), \quad c = \sinh(2\gamma), \quad 0 < |\gamma| < t \\
(AF) \quad a &= \sinh(\gamma - t), \quad b = \sinh(\gamma + t), \quad c = \sinh(2\gamma), \quad 0 \leq |t| < \gamma \\
(D) \quad a &= \sin(\gamma - t), \quad b = \sin(\gamma + t), \quad c = \sin(2\gamma), \quad 0 \leq |t| < \gamma < \frac{\pi}{2}
\end{align}

In the present work we calculate the asymptotics of the partition function $Z_N$ of the six-vertex model on the critical line between the disordered and ferroelectric phases which corresponds to

$$\frac{b}{c} - \frac{a}{c} = 1.$$
Figure 3. The phase diagram of the six-vertex model, with the relevant phases (F), (AF) and (D)

On the critical line we use the following parameterization of the weights:

\[ a = \frac{\alpha - 1}{2}, \quad b = \frac{\alpha + 1}{2}, \quad c = 1, \quad \alpha \in (1, \infty). \]  \hspace{1cm} (1.5)

The six-vertex model with DWBC was introduced by Korepin in [24], and then it was further studied in the works [23] and [13], leading to a determinantal formula for the partition function \( Z_N \), the Izergin-Korepin formula. On the D-F critical line, with weights parameterized as in (1.5), the Izergin-Korepin formula is

\[ Z_N(a, b, c) = \left( \frac{\alpha^2 - 1}{2} \right)^{N^2} \frac{\tau_N}{\prod_{k=0}^{N-1} k!^2}, \]  \hspace{1cm} (1.6)

where \( \tau_N \) is the Hankel determinant,

\[ \tau_N = \det \left( \frac{d^{i+j-2}}{d\alpha^{i+j-2}} \varphi \right)_{i,j=1}^N, \quad \varphi(\alpha) = \frac{2}{\alpha^2 - 1}. \]

The determinantal formula implies, in particular, that \( \tau_N \) solves the Toda equation,

\[ \tau_N \tau_N' - (\tau_N')^2 = \tau_{N+1} \tau_{N-1}, \quad N \geq 1, \quad (\cdot') = \frac{d}{d\alpha}. \]  \hspace{1cm} (1.7)

It was noticed by Zinn-Justin [28] that the Hankel determinant \( \tau_N \) can be connected to orthogonal polynomials: Since

\[ \varphi(\alpha) = \frac{1}{\alpha - 1} - \frac{1}{\alpha + 1} = \int_0^\infty e^{-\alpha x} (e^x - e^{-x}) \, dx \]  \hspace{1cm} (1.8)

we deduce the Zinn-Justin formula,

\[ \tau_N = \frac{1}{N!} \int_0^\infty \cdots \int_0^\infty w(x_j) \prod_{i<j} (x_i - x_j)^2 dx_1 \cdots dx_N, \]  \hspace{1cm} (1.9)

where

\[ w(x) = e^{-\alpha x} (e^x - e^{-x}). \]  \hspace{1cm} (1.10)
Now introduce monic orthogonal polynomials \( \{ p_n(x) = x^n + \ldots \}_{n \geq 0} \) with respect to the measure \( d\mu(x) = w(x)dx \) on the half-axis \([0, \infty)\),

\[
\int_0^\infty p_n(x)p_m(x)d\mu(x) = h_n\delta_{nm}
\] (1.11)

and obtain from (1.9) via the orthogonality condition, that

\[
\tau_N = \prod_{k=0}^{N-1} h_k.
\] (1.12)

The latter identity allows us to rewrite the Toda equation (1.7) on the critical line in the convenient form

\[
(\ln \tau_N)'' = \frac{h_N}{h_{N-1}}, \quad (') = \frac{d}{d\alpha},
\] (1.13)

and for the partition function, via (1.6),

\[
Z_N = \left( \frac{\alpha^2 - 1}{2} \right)^{N^2} \prod_{k=0}^{N-1} \frac{h_k}{(k!)^2}.
\] (1.14)

In [8], Bleher and Liechty derive the following large \( N \) asymptotics of the partition function \( Z_N \):

**Theorem 1.1** (see [8]). On the critical line between the disordered and ferroelectric phase region with \( \alpha > 1 \), as \( N \to \infty \),

\[
Z_N = CF^{N^2}G^{\sqrt{N}N^{1/4}} \left( 1 + O(N^{-1/2}) \right),
\] (1.15)

with

\[
F = \frac{\alpha + 1}{2}, \quad G = \exp \left[ -\zeta \left( \frac{3}{2} \right) \sqrt{\frac{\alpha - 1}{2\pi}} \right].
\]

Here \( \zeta(s) \) denotes the Riemann zeta function, \( C > 0 \), and the error term in (1.15) is uniform on any compact subset of the set

\[
\{ \alpha \in \mathbb{R} : \alpha > 1 \}.
\] (1.16)

The main result in the present paper is an explicit evaluation of the constant factor \( C > 0 \). We prove the following result:

**Theorem 1.2.** The constant factor \( C \) in asymptotic formula (1.15) is equal to

\[
C = e^c(\alpha - 1)^{1/4},
\] (1.17)

where

\[
c = \frac{1}{4}\ln 2 + \frac{1}{2}\ln \pi + \frac{1}{4\pi}\sum_{n=1}^\infty \left[ -\frac{\pi}{n} + \sum_{m=1}^\infty \frac{1}{(m+n)\sqrt{mn}} \right].
\] (1.18)

Remark: Using MAPLE for the numerical evaluation of the series, we obtain that

\[
\sum_{n=1}^\infty \left[ -\frac{\pi}{n} + \sum_{m=1}^\infty \frac{1}{(m+n)\sqrt{mn}} \right] = -3.568781612\ldots
\]

and

\[
c = 0.4616571210\ldots
\]
The calculation of the constant factor in the asymptotics of the partition function is a notoriously difficult problem. This problem appears not only in exactly solvable models of statistical mechanics, such as the six-vertex model and the Ising model, but also in random matrix theory, combinatorics, theory of integrable PDEs, etc. In different settings, the “constant factor problem” is studied in the works of Tracy [26], Basor and Tracy [3], Budylin and Buslaev [6], Ehrhardt [19], Deift, Its, Krasovsky, and Zhou [14], Deift, Its, and Krasovsky [15], Baik, Buckingham, and DiFranco [2], Bothner and Its [11], Forrester [22], and others.

To prove Theorem 1.2 we develop the Riemann-Hilbert approach to the double scaling limit of the partition function

\[ Z_N = C F^{N^2} G^N \left(1 + O\left(e^{-N^{1-\varepsilon}}\right)\right), \quad N \to \infty, \]

where

\[ C = 1 - e^{-4\gamma}, \quad G = e^{\gamma - t}, \quad F = \sinh(\gamma + t), \]

see [7], so that the constant factor \( C \) is known explicitly in the ferroelectric phase.

**Ferroelectric phase region.** In the ferroelectric phase region with parameterization (1.1), for any \( \varepsilon > 0, \)

\[ Z_N = C F^{N^2} G^N \left(1 + O\left(e^{-N^{1-\varepsilon}}\right)\right), \quad N \to \infty, \]

where

\[ C = 1 - e^{-4\gamma}, \quad G = e^{\gamma - t}, \quad F = \sinh(\gamma + t), \]

see [7], so that the constant factor \( C \) is known explicitly in the ferroelectric phase.

**Antiferroelectric phase region.** In the antiferroelectric phase region with parameterization (1.2),

\[ Z_N = C F^{N^2} \vartheta_4(N\omega) \left(1 + O\left(N^{-1}\right)\right), \quad N \to \infty, \]

where

\[ \omega = \frac{\pi}{2} \left(1 + \frac{t}{\gamma}\right), \quad F = \frac{\pi \left(\sinh(\gamma - t) \sin(\gamma + t)\right)}{2\gamma \vartheta_1(\omega)}, \]

and \( \vartheta_4(z) = \vartheta_4(z|q) \), \( \vartheta_4(z) = \vartheta_4(z|q) \) are the Jacobi theta functions with the elliptic nome \( q = e^{-\frac{\pi^2}{2t\gamma}} \), see [9]. It is known that the constant factor \( C \) does not depend on \( t \), so that

\[ C = C(\gamma) > 0, \tag{1.20} \]

but its exact value is not known.

**Disordered phase region.** In the disordered phase [6] with parameterization (1.3) for some \( \varepsilon > 0, \)

\[ Z_N = C F^{N^2} N^\kappa \left(1 + O\left(N^{-\varepsilon}\right)\right), \quad N \to \infty \]

with

\[ \kappa = \frac{1}{12} - \frac{2\gamma^2}{3\pi(\pi - 2\gamma)}, \quad F = \frac{\pi \left(\sin(\gamma - t) \sin(\gamma + t)\right)}{2\gamma \cos \frac{\pi t}{2\gamma}}, \]

It is known that the constant factor \( C > 0 \) has the following dependence on \( t \):

\[ C = C_0(\gamma) \left(\cos \frac{\pi t}{2\gamma}\right)^\kappa. \tag{1.21} \]
but the function $C_0(\gamma) > 0$ is not known.

Critical line between the antiferroelectric and disordered phase regions. Finally, on the critical line between the antiferroelectric and disordered phases \[5\] with the parameterization $a = 1 - x, b = 1 + x, c = 2, |x| < 1,$

\begin{equation}
(AF-D) \quad Z_N = CF^{N^2} N^{1/2} \left(1 + O \left(N^{-1}\right)\right), \quad N \to \infty
\end{equation}

where

$$F = \frac{\pi(1 - x^2)}{2 \cos \frac{\pi x}{2}}.$$ 

The constant factor $C > 0$ has the structure

$$C = C_0 \left(\cos \frac{\pi x}{2}\right)^{1/2},$$

where the universal constant $C_0 > 0$ is not known.

In the last three cases, the structural information \[1.20\], \[1.21\], and \[1.22\] on the constant factors is obtained by combining the results in \[9, 6, 5\] with the Toda equation. This can also be done in the present situation (see \[1.18\]), which then leaves us with the determination of the constants $c$ and $d$. In order to compute them, we use the double scaling asymptotics of the partition function as described above.

In \[8\], Bleher and Liechty rescaled the original weight \[1.10\] as

$$w^\alpha(x) = w \left(\frac{x}{\alpha - 1}\right) = e^{-x} - e^{-rx}, \quad r = \frac{\alpha + 1}{\alpha - 1} > 1$$

and studied the constants $h^\alpha_n$ associated with the monic orthogonal polynomials $\{p^\alpha_n(x)\}_{n \geq 0}$, satisfying the orthogonality condition

$$\int_0^\infty p^\alpha_n(x)p^\alpha_m(x)w^\alpha(x)\,dx = h^\alpha_n \delta_{nm}.$$ 

The main technical result in the work \[8\] is the following asymptotic formula for $h^\alpha_N$: As $N \to \infty$

$$\ln \left[ \frac{h^\alpha_N}{(N!)^2} \right] = -\frac{\zeta(3/2)}{2\pi(r - 1)N^{1/2}} + \frac{1}{4N} + O \left(N^{-3/2}\right)$$

which holds uniformly on any compact subset of the set \[1.10\]. Applying \[1.14\], this result implies immediately \[1.15\], in particular it gives the listed explicit expressions for $F$ and $G$. However we cannot take the limit $\alpha \to \infty$ in \[1.23\]. To overcome this difficulty, in addition to weight \[1.10\], we will study the related weight

$$w_t(x) = \frac{w(tx)}{2t} = xe^{-NV(x)}, \quad V(x) = x - \frac{\tau}{t} \ln S(tx), \quad t = \frac{N}{\alpha} = N\tau, \quad S(x) = \frac{\sinh x}{x}$$

and its associated monic orthogonal polynomials $\{p_{n,t}(x)\}_{n \geq 0}$, satisfying the orthogonality condition

$$\int_0^\infty p_{n,t}(x)p_{m,t}(x)w_t(x)\,dx = h_{n,t} \delta_{nm}.$$ 

Noticing that $h^\alpha_N = (\alpha - 1)^{2N+1}h_N$, we will prove the following generalization of \[1.23\]:
Theorem 1.3. As $N \to \infty$, 
\[
\frac{h_N}{(N!)^2} = \frac{N}{8} \exp \left[ N(l + 2) + \frac{v}{N} - \frac{1}{6N} + \varepsilon_N(\tau) \right], \quad \tau = \frac{1}{\alpha} \tag{1.25}
\]
where $\varepsilon_N$ is smooth in the parameter $\tau$ with 
\[
|\varepsilon_N| \leq \frac{c}{(N+1)^2}, \quad \left| \frac{d\varepsilon_N}{d\tau} \right| \leq \frac{c}{(N+1)^2}, \quad c > 0
\]
and the stated expansion (1.25) is uniform with respect to the parameter $0 \leq \tau \leq 1 - \varepsilon < 1$. Here, the parameter $b$ is determined implicitly via the equation 
\[
b = \frac{4}{1 - \tau} + \frac{2\tau}{(1 - \tau)t} I(2bt), \quad I(z) = -1 + \frac{1}{\pi} \int_0^1 \frac{u}{1 - u e^{zu} - 1} du, \quad z \geq 0, \tag{1.26}
\]
the parameter $l$ equals 
\[
l = 4(1 - \ln 2) - \frac{2}{(1 - \tau) - b + 2 \ln b - \frac{2\tau}{t}(1 - \ln 2) + \frac{2\tau}{t} J(2bt) + \frac{\tau}{t} \ln S(t)} \tag{1.27}
\]
with 
\[
J(z) = \frac{z}{\pi} \int_0^1 \left( \sqrt{\frac{u}{1 - u} - \arctan \sqrt{\frac{u}{1 - u}}} \right) du, \quad z \geq 0 \tag{1.28}
\]
and 
\[
v = \frac{3}{4bq(0)} - \frac{q'(b)}{4q^2(b)} + \frac{47}{12bq(b)}, \quad q(z) = \frac{1}{2\pi} \int_\Gamma \frac{w}{w - b (w - z)} dw, \tag{1.29}
\]
where $\Gamma$ is a counter-clockwise oriented contour containing $[0, b] \cup \{z\}$ in its interior such that $V(z)$ is analytic in the interior of $\Gamma$.

The proof of Theorem 1.3 is based on the Riemann-Hilbert approach for the orthogonal polynomials associated with the weight $w_t$, 
\[
w_t(x) = xe^{-NV(x)}, \quad x \geq 0; \quad V(z) = z(1 - \tau H(tz)), \quad H(z) = \frac{1}{z} \ln \left( \frac{\sinh z}{z} \right)
\]
where the potential $V$ is analytic in the strip 
\[
\Delta_t = \left\{ z \in \mathbb{C} : -\frac{\pi}{t} < \text{Im} \, z < \frac{\pi}{t} \right\}.
\]
This potential is somewhat close to the class of Laguerre potentials considered in the article of Vanlessen [27]. Our approach uses a combination of techniques from [27] and [8] to derive (1.25). The explicit form of $C$ in (1.17) will then follow from an interplay of the Toda equation (1.13) with (1.25) which we combine with (1.14). In particular we use the fact, that, as $\alpha \to \infty$ and $N$ is fixed, $w_t$ has the nontrivial limit 
\[
\lim_{\alpha \to \infty} w_t(x) = xe^{-Nx}, \quad x \geq 0
\]
and therefore the limiting orthogonal polynomials are classical Laguerre polynomials.

The setup for the remainder of the present paper is as follows. We prove Theorem 1.3 within the framework of the Riemann-Hilbert approach to orthogonal polynomials. We start in Section 2 with a construction of the equilibrium measure, which involves evaluation of the right endpoint $b$ of its support, its density, and the Lagrange multiplier $l$. Then, following the Deift-Zhou nonlinear steepest descent method, we carry out in Section 3 a sequence of transformations which allow us to approximate the solution of the initial Riemann-Hilbert problem by local model functions and by an iterative solution of a singular integral equation. As an application of this analysis, we prove
CALCULATION OF THE CONSTANT FACTOR IN THE SIX-VERTEX MODEL

in Section 4 Theorem 1.3. In Section 5 we use the Toda equation to derive formula (1.19) for the constant $C$. Then, in Section 6 we prove the double scaling limit asymptotics of the partition function. Finally, in Section 7 we prove Theorem 1.2.

2. Equilibrium measure

2.1. Definition of the equilibrium measure and evaluation of the endpoint of its support.

We have rescaled the original weight function $w(x)$ from (1.10) as

$$w_t(x) = xe^{-NV(x)}, \quad V(z) = z(1 - \tau H(tz)), \quad H(z) = \frac{1}{z} \ln \left( \frac{\sinh z}{z} \right), \quad t = N\tau = \frac{N}{\alpha},$$

hence the associated monic orthogonal polynomials $\{p_{n,t}(x)\}_{n \geq 0}$ are related to the initial ones via the relations

$$h_n = 2t^{2n+2}h_{n,t}, \quad p_n(x) = t^n p_{n,t}\left(\frac{x}{t}\right), \quad n \geq 0.$$

Our strategy now focuses on the determination of the large $N$ asymptotics of the normalizing constants $h_{N,t}$ and afterwards, via $h_N = 2t^{2N+2}h_{N,t}$, on the evaluation of $\tau_N$ from (1.12).

Notice that we can write the Hankel determinant as

$$\tau_N = \frac{2^{N}N(N+1)}{N!} \int_0^\infty \cdots \int_0^\infty \left( \prod_{j=1}^N y_j \right) e^{-N \sum_{j=1}^N V(y_j)} \prod_{i<j} (y_i - y_j)^2 dy_1 \cdots dy_N$$

which allows us, with the help of the empirical measure $\nu$ on $[0, \infty)$

$$\nu(s) = \frac{1}{N} \sum_{k=1}^N \delta(s - y_k), \quad \int_0^\infty d\nu(s) = 1,$$

to express parts of the integrand as

$$e^{-N \sum_{j=1}^N V(y_j)} \prod_{i<j} (y_i - y_j)^2 = e^{-N^2 H(\nu)}$$

with the energy functional

$$H(\nu) = \iint \ln |t - s|^{-1} \, d\nu(t) d\nu(s) + \int V(s) d\nu(s).$$

This observation leads to the expectation that the value of $\tau_N$, as $N \to \infty$, will be concentrated in a vicinity of the global minimum of the functional $H(\nu)$, with $\nu$ varying over

$$\mathcal{M}^1[0, \infty) = \left\{ \mu \in \text{Borel measures on } [0, \infty) : \int d\mu = 1 \right\}.$$

But it is well known (cf. [16, 17]) that the minimization problem

$$E^V = \inf_{\mu \in \mathcal{M}^1[0, \infty)} \left[ \iint \ln |t - s|^{-1} d\mu(t) d\mu(s) + \int V(s) d\mu(s) \right]$$

has a unique solution $\mu = \mu^V \in \mathcal{M}^1[0, \infty)$, called the equilibrium measure. We now begin to gather various characteristics of the equilibrium measure:

Since the underlying potential $V(z) = z(1 - \tau H(tz))$ is convex, the support of the equilibrium measure $\mu^V$ consists of a single interval

$$J = [0, b] \subset \mathbb{R}.$$
Our first goal is to derive an expansion for the right endpoint \( b \), as \( N \to \infty \) for different values of the double scaling parameter \( t \). To this end use the \( g \)-function

\[
g(z) = \int_{\mathbb{J}} \ln(z-w) d\mu V(w) = \int_{0}^{b} \ln(z-w) \psi(w) dw, \quad z \in \mathbb{C}\setminus(-\infty, b] \tag{2.1}
\]

with the principal branch chosen in the logarithm. The equilibrium measure determines the \( g \)-function by definition, but on the other hand the \( g \)-function determines the equilibrium measure uniquely by the following variational conditions: there exists a real constant \( l \), the Lagrange multiplier, such that

\[
z \in [0, +\infty) \setminus \mathbb{J} : \quad g_+(z) + g_-(z) - V(z) - l \leq 0, \quad z \in \mathbb{J} : \quad g_+(z) + g_-(z) - V(z) - l = 0 \tag{2.2}
\]

The latter equality on the support \( \mathbb{J} \), leads to an additive Riemann-Hilbert problem for \( g'(z) \) which can be solved explicitly

\[
g'(z) = \frac{1}{2\pi} \sqrt{\frac{z}{z-b}} \int_{0}^{b} \frac{w}{b-w} \sqrt{V'(w)} dw, \quad z \in \mathbb{C}\setminus[0, b] \tag{2.3}
\]

and comparing the large \( z \)-asymptotics of the last equation with the one obtained from (2.1), we derive the following defining equation on the right endpoint \( b \)

\[
\frac{1}{2\pi} \int_{0}^{b} \frac{w}{b-w} \sqrt{V'(w)} dw = 1.
\]

Since

\[
V'(z) = 1 - \tau \left( \frac{\cosh(tz)}{\sinh(tz)} - \frac{1}{tz} \right) = 1 - \tau \left( 1 - \frac{1}{tz} + \frac{2}{e^{2tz} - 1} \right)
\]

we obtain from (2.3) after the change of variables \( w = bu \)

\[
b = \frac{4}{1-\tau} + \frac{2\tau}{(1-\tau)t} I(2bt), \quad I(z) = -1 + \frac{z}{\pi} \int_{0}^{1} \frac{u}{1-u e^{zu} - 1} du, \quad z \geq 0
\]

which is equation (1.26) in Theorem 1.3. We will solve the last equation for \( b \) iteratively, before that, let us study the asymptotic behavior of \( I(z) \) as \( z \to 0 \) and \( z \to +\infty \).

**Proposition 2.1.** The function \( I(z) \) is analytic in the strip

\[
\Delta = \{ z \in \mathbb{C} : -\pi < \text{Im} \, z < \pi \}
\]

with

\[
I(z) = -\frac{z}{4} + \frac{z^2}{32} + O(z^3), \quad z \to 0,
\]

and as \( z \to +\infty \),

\[
I(z) = -1 + \frac{\zeta(3/2)}{2\sqrt{\pi} z^{1/2}} + \frac{3\zeta(5/2)}{8\sqrt{\pi} z^{3/2}} + O(z^{-5/2}).
\]

**Proof.** Analyticity of \( I(z) \) in \( \Delta \) follows immediately from the analyticity of \( \frac{z}{e^z-1} \) in \( \Delta \), hence we are left with the two asymptotic expansions. When \( z \to 0 \), we use the asymptotic formula,

\[
\frac{1}{e^z - 1} = \frac{1}{z} - \frac{1}{2} + \frac{z}{12} + O(z^2), \quad z \to 0
\]
combined with the integrals,
\[
\int_0^1 \frac{du}{\sqrt{u(1-u)}} = \pi, \quad \int_0^1 \sqrt{\frac{u}{1-u}} \, du = \frac{\pi}{2}, \quad \int_0^1 u \sqrt{\frac{u}{1-u}} \, du = \frac{3\pi}{8}
\]
to obtain
\[
I(z) = -1 + \frac{z}{\pi} \int_0^1 \sqrt{\frac{u}{1-u}} \left( \frac{1}{zu} - \frac{1}{2} + \frac{zu}{12} + O(z^2u^2) \right) \, du = -\frac{z}{4} + \frac{z^2}{32} + O(z^3),
\]
which is (2.4). When \( z \to +\infty \), we use the asymptotic formula,
\[
\sqrt{\frac{u}{1-u}} = \frac{u}{2} + \frac{u^3}{2} + O(u^5), \quad u \to 0,
\]
and the integrals,
\[
\int_0^\infty \frac{u^{1/2}}{e^u-1} \, du = \frac{\sqrt{\pi}}{2} \zeta(3/2), \quad \int_0^\infty \frac{u^{3/2}}{e^u-1} \, du = \frac{3\sqrt{\pi}}{4} \zeta(5/2),
\]
which gives (2.5). \( \square \)

Let us now return to equation (1.26). Since \( \alpha > 1 \), we have that \( \tau < 1 \) and we will in fact assume from now on, that \( \tau \) is separated from 1, so that
\[
0 \leq \tau \leq 1 - \varepsilon < 1,
\]
where \( \varepsilon > 0 \) is fixed throughout the remainder of this paper. To solve (1.26) for \( b \), use iterations
\[
b_j = \frac{4}{1-\tau} + \frac{2\tau}{(1-\tau)t} I(2b_{j-1}), \quad j \geq 1 \quad b_0 = \frac{4}{1-\tau}. \quad (2.6)
\]
Consider the mapping
\[
b \mapsto \frac{4}{1-\tau} + \frac{2\tau}{(1-\tau)t} I(2b)
\]
which satisfies
\[
\frac{df}{db} = \frac{4\tau}{(1-\tau)} I'(2b).
\]
From (2.6), after differentiation, we obtain the estimate,
\[
\left| \frac{df}{db} \right| \leq \frac{C\tau}{1+\varepsilon^3/2}, \quad t > 0, \quad b > 1,
\]
where \( C > 0 \) is a constant independent of \( \tau \) and \( t \), i.e. the mapping \( f \) is contracting for small \( \tau \) in a neighborhood of the point \( b_0 \), and hence \( f \) has a fixed point \( b \) which can be obtained as a limit of the iterations
\[
b_j = f(b_{j-1}), \quad j \geq 1.
\]
In addition, we obtain the estimate of the difference \( |b_j - b| \) as
\[
|b_j - b| \leq \hat{C} \left( \frac{\tau}{1+\varepsilon^3/2} \right)^{j+1}, \quad \hat{C} > 0. \quad (2.7)
\]
Back to (2.6), we have in the first iteration
\[
b_1 = \frac{4}{1-\tau} + \frac{2\tau}{(1-\tau)t} I \left( \frac{8t}{1-\tau} \right)
\]
and in the second,
\[ b_2 = \frac{4}{1 - \tau} + \frac{2\tau}{(1 - \tau)t} I(2tb_1) = \frac{4}{1 - \tau} + \frac{2\tau}{(1 - \tau)t} I \left( \frac{8t}{1 - \tau} + \frac{4t\tau}{(1 - \tau)t} I \left( \frac{8t}{1 - \tau} \right) \right). \tag{2.8} \]

Combining now (2.8) with (2.7) we obtain

**Proposition 2.2.** As \( N \to \infty \), the right endpoint \( b \) of the equilibrium measure has the asymptotic behavior,
\[ b = \frac{4}{1 - \tau} + \frac{2\tau}{(1 - \tau)t} I \left( \frac{8t}{1 - \tau} + \frac{4t\tau}{(1 - \tau)t} I \left( \frac{8t}{1 - \tau} \right) \right) + O \left( \left( \frac{\tau}{1 + t^{3/2}} \right)^3 \right), \tag{2.9} \]
which is uniform with respect to the parameters \( 0 \leq \tau \leq 1 - \varepsilon < 1 \) and \( t \geq 0 \).

At this point we would like to collect some facts on the density \( \psi(x), x \in [0, b] \) of the equilibrium measure as introduced in (2.1).

### 2.2. Evaluation of the density of the equilibrium measure.

We use [17] and [27], more precisely the identities
\[ \psi(x) = \frac{1}{2\pi} \sqrt{\frac{b - x}{x}} q(x), \quad x \in [0, b] \]
with (compare (1.29))
\[ q(z) = \frac{1}{2\pi i} \oint_\Gamma \frac{V'(w)}{w - b w - z} dw \]
where \( \Gamma \) is a counter-clockwise oriented contour containing \([0, b] \cup \{z\}\) in its interior such that \( V(z) \) is analytic in the interior of \( \Gamma \). Replacing \( V'(w) \) by
\[ V'(z) = 1 - \tau k(tz), \quad k(z) = \frac{\cosh z}{\sinh z} - \frac{1}{z} \]
we obtain after applying residue theorem
\[ q(z) = 1 + \tau s(z, t), \quad s(z, t) = -\frac{1}{2\pi i} \oint_\Gamma \frac{k(tw)}{w - b w - z} dw. \tag{2.10} \]

The properties of the function \( s(z, t) \) will be important for us. They are described as follows:

**Proposition 2.3.** The function \( s(z, t) \) is real analytic on the set \([0, b] \times \mathbb{R}\). As \( t \to 0 \),
\[ s(z, t) = -\frac{t}{3} \left( z + \frac{b}{2} \right) + \frac{t^3}{45} \left( z^3 + \frac{b^3}{2} \frac{z^2}{8} + \frac{3b^2}{16} z + \frac{5b^3}{16} \right) + O(t^5), \tag{2.11} \]
and as \( t \to \infty \),
\[ s(z, t) = -1 + O(t^{-1/2}), \quad \frac{\partial s(z, t)}{\partial z} = O(t^{-1/2}), \tag{2.12} \]
uniformly in \( z \in [0, b] \).

**Proof.** The integrand in (2.10) is analytic with respect to \((z, t) \in [0, b] \times \mathbb{R}\), hence \( s(z, t) \) is analytic as well and \( s(z, t) \) is real-valued since the contour \( \Gamma \) can be deformed to the interval \([0, b]\) covered twice. Let us now derive the asymptotic formulae for \( s(z, t) \). When \( t \to 0 \), use
\[ k(z) = \frac{z}{3} - \frac{z^3}{45} + O(z^5), \quad z \to 0 \]
and obtain, as $t \to 0$, 
\[ s(z, t) = -\frac{1}{2\pi i} \oint_{\Gamma} \sqrt{\frac{w}{w-b}} \frac{tw}{w-z} \, dw + \frac{1}{2\pi i} \oint_{\Gamma} \sqrt{\frac{w}{w-b}} \frac{(tw)^3}{45} \, dw + O(t^5), \]

hence equation (2.11) follows from residue theorem, noticing that
\[ \sqrt{\frac{w}{w-b}} = 1 + \frac{1}{w} \left( z + \frac{b}{2} \right) + \frac{1}{w^2} \left( z^2 + \frac{3b^2}{8} \right) + \frac{1}{w^3} \left( z^3 + \frac{3b^2}{2} \right) \]
\[ + \frac{3b^2}{8} z + \frac{5b^3}{16} + O(w^{-4}), \quad |w| \to \infty. \]

For the expansions (2.12), we rewrite $s(z, t)$ as
\[ s(z, t) = -\frac{1}{2\pi i} \oint_{\Gamma} \sqrt{\frac{w}{w-b}} \left( 1 - \frac{1}{tw} + \frac{2}{e^{2tw} - 1} \right) \, dw = -1 - \frac{1}{2\pi i} \oint_{\Gamma} \sqrt{\frac{w}{w-b}} \frac{2}{e^{2tw} - 1} \, dw, \]

where the last equality follows once more from residue theorem. After the change of variables $u = 2tw$,
\[ s(z, t) = -1 - \frac{1}{2\pi i} \oint_{2\Gamma} \sqrt{\frac{u}{u-2tb}} \frac{2}{e^{2tw} - 1} \, du \]

and we now choose the contour $2\Gamma$ to be a long “stadium”, so that it consists of two parallel segments, $\{u = x \pm i, 0 \leq x \leq 2tb\}$ and two semicircles of radius 1, around the points $u = 0$ and $u = 2tb$. With this choice
\[ \left| \sqrt{\frac{u}{u-2tb}} \frac{2}{e^{2tw} - 1} \frac{1}{u-2tz} \right| \leq \frac{C}{\sqrt{1+t}}, \quad u \in 2\Gamma, \]

and we obtain the first estimation in (2.12). For the second, we differentiate with respect to $z$, i.e.
\[ \frac{\partial s(z, t)}{\partial z} = -\frac{1}{2\pi i} \oint_{\Gamma} \sqrt{\frac{w}{w-b}} \frac{2}{e^{2tw} - 1} \frac{dw}{(w-z)^2}, \]

and change again variables $u = 2tw$. Estimating the latter integral from above, we obtain the remaining estimation in (2.12).

We can now combine (2.10) with Proposition 2.3 and deduce
\[ \sup_{0 \leq y \leq b} |g(y) - 1 + \tau| = O \left( \frac{\tau}{\sqrt{1+t}} \right), \quad \sup_{0 \leq y \leq b} |g'(y)| = O \left( \frac{\tau}{\sqrt{1+t}} \right), \]

which is uniform with respect to the parameters $0 \leq \tau \leq 1 - \varepsilon < 1$ and $t \geq 0$.

We are left with the computation of the Lagrange multiplier.

2.3. Evaluation of the Lagrange multiplier. We will compute the multiplier $l$ via (2.24),
\[ l = 2g(b) - V(b), \]

in other words, we have to compute two quantities. For $g(b)$, use the formula
\[ g(b) = \ln b - \int_{b}^{\infty} \left( \omega(z) - \frac{1}{z} \right) \, dz, \]
which involves the resolvent \( \omega(z) \equiv g'(z) \) and which can be derived immediately from the expansion

\[
g'(z) = \int_0^b \frac{d\mu V(w)}{z-w} = \frac{1}{z} + O(z^{-2}), \quad z \to \infty.
\]

As we have already seen,

\[
\omega(z) = \frac{1}{2\pi} \sqrt{\frac{z-b}{z}} \int_0^b \sqrt{\frac{w}{b-w}} \frac{V'(w)}{z-w} \, dw,
\]

and the latter equality can be rewritten as (cf. [17])

\[
\omega(z) = \frac{V'(z)}{2} - \sqrt{\frac{z-b}{z}} q(z) - \frac{2}{z}, \quad z \in \mathbb{C}\setminus[0,b].
\]

Back to (2.15), this implies

\[
g(b) = \ln b - \frac{1}{2} \int_b^\infty \left( V'(z) - \sqrt{\frac{z-b}{z}} q(z) - \frac{2}{z} \right) \, dz.
\]

Deforming the contour of integration in (2.13) and evaluating the residue at \( w = z \), we have

\[
s(z,t) = -1 - \sqrt{\frac{z}{z-b e^{2tz} - 1}} - \frac{1}{\pi} \int_0^b \sqrt{\frac{w}{b-w e^{2tw} - 1}} \frac{2}{w-z} \, dw
\]

and with

\[
V'(z) = 1 - \tau \left( 1 - \frac{1}{t z} + \frac{2}{e^{2tz} - 1} \right)
\]

therefore

\[
g(b) = \ln b - \frac{1}{2} \int_b^\infty \left[ 1 - \tau + \frac{\tau}{t z} - \frac{2\tau}{e^{2tz} - 1} - \sqrt{\frac{z-b}{z}} \left( 1 - \tau - \sqrt{\frac{z}{z-b e^{2tz} - 1}} \right) \right] \, dz,
\]

or after simplifications,

\[
\begin{align*}
g(b) &= \ln b - \frac{1}{2} \int_b^\infty \left[ (1-\tau) \left( 1 - \sqrt{\frac{z-b}{z}} \right) + \frac{\tau}{t z} - \frac{2}{z} + \sqrt{\frac{z-b}{z}} \frac{\tau}{\pi} \right. \\
&\quad \left. \times \int_0^b \sqrt{\frac{w}{b-w e^{2tw} - 1}} \frac{2}{w-z} \, dw \right] \, dz.
\end{align*}
\]

(2.16)

At this point we use (1.26) and write

\[
-\frac{\tau}{z\pi} \int_0^b \sqrt{\frac{w}{b-w e^{2tw} - 1}} \frac{2}{w-z} \, dw = \frac{1}{z} \left( 2 - \frac{b}{2} (1-\tau) - \frac{\tau}{t} \right),
\]

hence (2.16) reads as

\[
g(b) = \ln b + I_1 + I_2,
\]

(2.17)
where
\[ I_1 = -\frac{1}{2} \int_b^\infty (1 - \tau) \left( 1 - \sqrt{\frac{z - b}{z}} \right) + \frac{\tau}{tz} - \frac{2}{z} + \frac{1}{z} \sqrt{\frac{z - b}{z}} \left( 2 - \frac{b}{2} (1 - \tau) - \frac{\tau}{t} \right) \] dz,
and
\[ I_2 = \frac{\tau}{\pi} \int_b^\infty \sqrt{\frac{z - b}{z}} \left[ \int_0^b \frac{w}{\sqrt{b - w} (e^{2ztw} - 1)} \right] \] dz.

The term \( I_1 \) is calculated explicitly,
\[ I_1 = 2(1 - \ln 2) - \frac{b}{4} (1 - \tau) - \frac{\tau}{t} (1 - \ln 2) = 2 - 2 \ln 2 - \frac{b}{4} (1 - \tau) - \frac{1}{N} + \frac{\ln 2}{N}, \]
and in \( I_2 \) we change the order of integration: Since
\[ \int_b^\infty \sqrt{\frac{z - b}{z}} \frac{dz}{z(z - w)} = \frac{2}{w} \left( 1 - \sqrt{\frac{b - w}{w}} \arctan \sqrt{\frac{b - w}{w}} \right), \quad 0 < w < b, \]
we obtain
\[ I_2 = \frac{2\tau}{\pi} \int_0^b \left( \sqrt{\frac{w}{b - w}} - \arctan \sqrt{\frac{w}{b - w}} \right) \frac{dw}{e^{2ztw} - 1} = \frac{\tau}{t} J(2bt) \] (2.18)
with (compare (1.28))
\[ J(z) = \frac{z}{\pi} \int_0^1 \left( \sqrt{\frac{u}{1 - u}} - \arctan \sqrt{\frac{u}{1 - u}} \right) \frac{du}{e^{zu} - 1}. \]

Some important properties of the function \( J(z) \) are summarized below.

**Proposition 2.4.** The function \( J(z) \) is analytic in the horizontal strip \( \Delta \). As \( z \to 0 \),
\[ J(z) = 1 - \ln 2 - \frac{z}{8} + \frac{7z^2}{384} + O \left( z^3 \right), \] (2.19)
and as \( z \to +\infty \),
\[ J(z) = \frac{\zeta(5/2)}{4 \sqrt{\pi z^{3/2}}} + \frac{9 \zeta(7/2)}{16 \sqrt{\pi z^{5/2}}} + O \left( z^{-7/2} \right). \] (2.20)

**Proof.** Our reasoning is almost identical to the one given in the proof of Proposition 2.1 in particular analyticity follows from the analyticity of \( \frac{z}{e^{z-1}} \) in \( \Delta \). When \( z \to 0 \), we use the integrals
\[ \int_0^1 \left( \sqrt{\frac{u}{1 - u}} - \arctan \sqrt{\frac{u}{1 - u}} \right) \frac{du}{u} = \frac{\pi}{4} (1 - \ln 2) \]
\[ \int_0^1 \left( \sqrt{\frac{u}{1 - u}} - \arctan \sqrt{\frac{u}{1 - u}} \right) du = \frac{\pi}{4}, \quad \int_0^1 \left( \sqrt{\frac{u}{1 - u}} - \arctan \sqrt{\frac{u}{1 - u}} \right) u \, du = \frac{7\pi}{32} \]
and obtain

\[ J(z) = \frac{z}{\pi} \int_0^1 \left( \sqrt{\frac{u}{1-u}} - \arctan \sqrt{\frac{u}{1-u}} \right) \left( \frac{1}{zu} - \frac{1}{2} + \frac{zu}{12} + O \left( z^2 u^2 \right) \right) du \]

\[ = 1 - \ln 2 - \frac{z}{8} + \frac{7z^2}{384} + O \left( z^3 \right), \]

which is (2.19). When \( z \to +\infty \), we use the expansion

\[ \sqrt{\frac{u}{1-u}} - \arctan \sqrt{\frac{u}{1-u}} = \frac{u^{3/2}}{3} + \frac{3}{10} u^{5/2} + O \left( u^{7/2} \right), \quad u \to 0, \]

and the integrals,

\[ \int_0^\infty \frac{u^{3/2}}{e^u - 1} du = \frac{3\sqrt{\pi}}{4} \zeta \left( \frac{5}{2} \right), \quad \int_0^\infty \frac{u^{5/2}}{e^u - 1} du = \frac{15\sqrt{\pi}}{8} \zeta \left( \frac{7}{2} \right), \]

which gives (2.20).

In the end we go back to (2.17) and summarize

\[ g(b) = \ln b + 2(1 - \ln 2) - \frac{b}{4}(1 - \tau) - \frac{\tau}{t}(1 - \ln 2) + \frac{\tau}{t} J(2bt), \]

which, combined with \( V(b) = b - \frac{\tau}{t} \ln S(bt) \), gives equation (1.27), i.e.

\[ l = 4(1 - \ln 2) - \frac{b}{2}(1 - \tau) - b + 2 \ln b - \frac{2\tau}{t}(1 - \ln 2) + \frac{2\tau}{t} J(2bt) + \frac{\tau}{t} \ln S(bt). \]  

(2.21)

At this point we have gathered enough information to begin the asymptotical analysis.

3. RIEMANN-HILBERT APPROACH

3.1. Riemann-Hilbert problem for orthogonal polynomials. We will solve the Fokas-Its-Kitaev [21] Riemann-Hilbert problem (RHP) for orthogonal polynomials asymptotically: Find a \( 2 \times 2 \) piecewise analytic matrix-valued function \( Y(z) = Y^{(n)}(z) \) such that

- \( Y^{(n)}(z) \) is analytic for \( z \in \mathbb{C} \setminus [0, \infty) \)
- Orienting the half ray \([0, \infty)\) from left to right the following jump relation holds

  \[ Y_+^{(n)}(z) = Y_-^{(n)}(z) \begin{pmatrix} 1 & w_t(z) \\ 0 & 1 \end{pmatrix}, \quad z \in [0, \infty) \]

- At the endpoint \( z = 0, Y(z) \) remains bounded, i.e.

  \[ Y(z) = O(1), \quad z \to 0, \quad z \in \mathbb{C} \setminus [0, \infty) \]

- As \( z \to \infty \), we have

  \[ Y^{(n)}(z) = \left( I + O(z^{-1}) \right) z^{\sigma_3}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \]

The unique solution \( Y^{(n)}(z) \) to the latter problem is given by

\[ Y^{(n)}(z) = \begin{pmatrix} p_{n,t}(z) & \frac{1}{2\pi i} \int_0^\infty p_{n,t}(s/w_t(z))ds \\ \gamma_{n-1}p_{n-1,t}(z) & \frac{1}{2\pi i} \int_0^\infty p_{n-1,t}(s/w_t(z))ds \\ \end{pmatrix} \]
where \( p_{n,t}(z) = z^n + \ldots \) is the \( n \)th monic orthogonal polynomial with respect to the measure \( d\mu(s) = \omega_t(s)ds \) supported on the half-ray \([0, \infty)\) and

\[
\gamma_n = -\frac{2\pi i}{h_{n,t}}, \quad h_{n,t} = \int_0^\infty p_{n,t}^2(s)d\mu(s).
\]

Also, \( Y^{(n)}(z)z^{-n\sigma_3} \) has a full asymptotic expansion near infinity:

\[
Y^{(n)}(z)z^{-n\sigma_3} = I + \frac{1}{z} + O\left(\frac{1}{z^2}\right), \quad z \to \infty, \quad Y^{(n)}_k(z) = \left(Y^{(n)}_k\right)_{ij},
\]

which connects to the normalizing constants via

\[
h_{n,t} = -2\pi i \left(Y^{(n)}_1\right)_{12}. \tag{3.1}
\]

Since we want to compute the large \( N \) asymptotics of \( h_{N,t} \), we therefore have to solve the given RHP for \( Y(z) = Y^{(N)}(z) \). This solution will be derived in the framework of the Deift-Zhou nonlinear steepest descent method \([18]\) employing techniques which have been developed in \([17, 27]\) and \([8]\). We will approximate the global solution \( Y(z) \) with the help of solutions of certain Riemann-Hilbert model problems and the iterative solution of a singular integral equations. The necessary steps are worked out in the following subsections.

### 3.2. First transformation of the RHP - normalization

Recall (2.1) and employ the following normalizing substitution in the original \( Y \)-RHP

\[
Y(z) = \exp\left(\frac{Nl}{2}\sigma_3\right)T(z)\exp\left(\frac{N(g(z) - \frac{l}{2})}{2}\sigma_3\right), \quad z \in \mathbb{C}\setminus\mathbb{R}. \tag{3.2}
\]

This leads to a RHP for the function \( T(z) \):

- \( T(z) \) is analytic for \( z \in \mathbb{C}\setminus[0, \infty) \)
- From the jump properties of \( g(z) \), compare (2.2), we get

\[
T_+(z) = T_-(z) \begin{pmatrix} e^{-N(g_+ - g_-)} & z \\ 0 & e^{N(g_+ - g_-)} \end{pmatrix}, \quad z \in [0, b]
\]

and

\[
T_+(z) = T_-(z) \begin{pmatrix} 1 & ze^{-N(g_+ + g_- - V - l)} \\ 0 & 1 \end{pmatrix}, \quad z \in [0, \infty)\setminus[0, b].
\]

- As \( z \to 0 \) and \( z \in \mathbb{C}\setminus[0, \infty) \), the function \( T(z) \) is bounded,

\[
T(z) = O(1), \quad z \to 0, \quad z \in \mathbb{C}\setminus[0, \infty).
\]

- At infinity, \( T(z) \) is normalized as follows

\[
T(z) = I + O\left(\frac{1}{z}\right), \quad z \to \infty.
\]

We now take a closer look at the listed jumps: First by the Euler Lagrange variational condition (2.2)

\[
g_+(z) + g_-(z) - V(z) - l < 0, \quad z \in [0, \infty)\setminus[0, b],
\]

hence for \( z \in (b + \eta, \infty), \eta > 0 \) fixed,

\[
\begin{pmatrix} 1 & ze^{N(g_+ + g_- - V - l)} \\ 0 & 1 \end{pmatrix} \to I, \quad N \to \infty
\]

where the stated convergence is exponentially fast. Secondly on the line segment \([0, b] \): Since \( g_-(z) = V(z) - g_+(z) + l, z \in [0, b] \) the function

\[
G(z) = g_+(z) - g_-(z) = 2g_+(z) - V(z) - l
\]
admits analytical continuation in a (in general $t$-dependent) neighborhood of the line segment $[0, b]$ into the upper half-plane. Here we use in particular that $V(z)$ is analytic in the strip $\Delta_t$. On the other hand

$$G(z) = 2\pi i \int_{z}^{b} \psi(w) dw, \quad z \in [0, b]$$

and therefore

$$\frac{d}{dy}G(z + iy) \bigg|_{y=0} = 2\pi \psi(z) > 0, \quad z \in (0, b),$$

i.e. the stated local continuation of $G(z)$ into the upper half-plane satisfies

$$\text{Re } G(z) > 0 \quad \text{for } \text{Im } z > 0. \quad (3.3)$$

In the lower halfplane we argue in a similar fashion, indeed

$$G(z) = -2g_-(z) + V(z) + l$$

admits local (in general into a $t$-dependent neighborhood) continuation into the lower half-plane satisfying

$$\text{Re } G(z) < 0 \quad \text{for } \text{Im } z < 0. \quad (3.4)$$

These continuations will now be used in the following matrix factorizations

$$
\begin{pmatrix}
\frac{1}{4} e^{-NG(z)} & 0 \\
0 & \frac{1}{4} e^{NG(z)}
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
= S_{L_1} S_P S_{L_2}, \quad z \in (0, b),
$$

motivating the second transformation of the RHP.

### 3.3. Second transformation of the RHP - opening of lenses.

Let $L^\pm$ denote the upper (lower) lens, shown in Figure 4 which is bounded by the contour $\gamma^\pm$. Define

$$S(z) = \begin{cases} 
T(z) S_{L_2}^{-1}, & z \in L^+, \\
T(z) S_{L_1}, & z \in L^-, \\
T(z), & \text{otherwise},
\end{cases} \quad (3.5)$$

then $S(z)$ solves the following RHP

![Figure 4. The second transformation - opening of lenses](image)

- $S(z)$ is analytic for $z \in \mathbb{C}\setminus([0, \infty) \cup \Gamma)$, with $\Gamma = \gamma^+ \cup \gamma^-$
- The following jumps hold, with orientation fixed as in Figure 4

$$S_+(z) = S_-(z) \begin{cases} 
\begin{pmatrix} 
\frac{1}{4} e^{-NG(z)} & 0 \\
0 & \frac{1}{4} e^{NG(z)}
\end{pmatrix}, & z \in \gamma^+, \\
\begin{pmatrix} 
0 & 1 \\
1 & 0
\end{pmatrix}, & z \in (0, b), \\
\begin{pmatrix} 
1 & 0 \\
0 & 1
\end{pmatrix}, & z \in [0, \infty)\setminus[0, b], \\
\begin{pmatrix} 
1 & 0 \\
0 & 1
\end{pmatrix}, & z \in \gamma^-.
\end{cases}$$
For the behavior at the origin, we see from the behavior of $T(z)$ and (3.5), that
\[ S(z) = O(1), \quad z \to 0, \quad z \in \mathbb{C}\setminus(L^+ \cup L^-) \]  
and
\[ S(z) = O(z^{-1}), \quad z \to 0, \quad z \in L^+ \cup L^- \]  

At infinity, $S(z) = I + O(z^{-1}), z \to \infty$.

Recalling (3.3) and (3.4) as well as the behavior of the jump matrix on the infinite ray $(b, \infty)$ we expect, and this will be justified rigorously, that as $N \to \infty$, $S(z)$ converges to a solution of the model RHP, in which we only have to deal with the jump matrix on the line segment $(0, b)$. Let us now consider this model RHP.

### 3.4. The model RHP

Find a piecewise analytic $2 \times 2$ matrix valued function $M(z)$ such that

- $M(z)$ is analytic for $z \in \mathbb{C}\setminus[0, b]$
- Along $[0, b]$, the following jump holds: $M_+ = M(z), \quad z \in [0, b]$
- $M(z) = I + O(z^{-1}), z \to \infty$

A solution to this problem can be obtained as follows. We introduce
\[ N(z) = M(z)D(z)^{\sigma_3}, \quad z \in \mathbb{C}\setminus[0, b] \]
where the scalar Szegő function $D(z)$ satisfies
\[ D_+D_-(z) = z, \quad z \in [0, b] \]  

Such a function indeed exists, namely
\[ D(z) = \exp \left[ \frac{\sqrt{z(z-b)}}{2\pi i} \int_0^b \frac{\ln w}{\sqrt{w(w-b)+w-z}} \frac{dw}{w(z-b)^{1/4}} \right] = \sqrt{\frac{b}{2}} \left( z - \frac{b}{2} + \sqrt{z(z-b)} \right)^{-1/2} \]
where we choose principal branches for all fractional power functions. The latter choice of $D(z)$ transforms the original model problem to a RHP for $N(z)$ with jump
\[ N_+ = N_-(z) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad z \in [0, b] \]
which can be solved via diagonalization. Noticing further that
\[ D(z) = \sqrt{\frac{b}{2}} \left( 1 + \frac{b}{4z} + \frac{b^2}{8z^2} + O(z^{-3}) \right), \quad z \to \infty \]  
we obtain
\[ M(z) = \left( \sqrt{\frac{b}{2}} \right)^{\sigma_3} \frac{i}{2} \begin{pmatrix} \delta + \delta^{-1} & i(\delta - \delta^{-1}) \\ -i(\delta - \delta^{-1}) & \delta + \delta^{-1} \end{pmatrix} D^{-\sigma_3}(z) \]  
with
\[ \delta(z) = \left( \frac{z}{z-b} \right)^{1/4} \]
defined on $\mathbb{C}\setminus[0, b]$ with its branch fixed by the condition $(\frac{z}{z-b})^{1/4} \to 1$ as $z \to \infty$. Before moving on, we note for future purposes that
\[ M(z) = I + \frac{b}{4z} \begin{pmatrix} -1 & \frac{b}{4} \\ \frac{b}{4} & 1 \end{pmatrix} + O(z^{-2}), \quad z \to \infty. \]
3.5. **Construction of a parametrix at** \( z = b \). Fix a small neighborhood \( \mathcal{U} \) of the point \( b \) and observe that

\[
G(z) = 2g(z) - V(z) - l = b \int \frac{w - b}{w} q(w)dw = - \frac{2}{3} h_1(z)(z - b)^{3/2}, \quad z \in \mathcal{U} \cap \gamma^+
\]  

(3.11)

where \( h_1(z) \) is an analytic function in \( \mathcal{U} \) such that

\[
h_1(z) = \frac{q(b)}{\sqrt{b}} \left[ 1 + \frac{3}{5} \left( \frac{q'(b)}{q(b)} - \frac{1}{2b} \right) (z - b) + O((z - b)^2) \right], \quad z \to b,
\]

moreover the function \((z - b)^{3/2}\) is defined for \( z \in \mathbb{C} \setminus (-\infty, b] \) and fixed by the condition

\[
(z - b)^{3/2} > 0 \quad \text{if} \quad z > b.
\]

Similarly

\[
G(z) = -2g(z) + V(z) + l = \frac{2}{3} a(z)(z - b)^{3/2}, \quad z \in \mathcal{U} \cap \gamma^-
\]

and

\[
g_+(z) + g_-(z) - V(z) - l = - b \int \frac{w - b}{w} q(w)dw = - \frac{2}{3} a(z)(z - b)^{3/2},
\]

as \( z \in \mathcal{U}, z > b \). The stated local behaviors suggest to use the Airy function \( \text{Ai}(\zeta) \) in the construction of an edge point parametrix, we follow the notation of [5]: For \( \zeta \in \mathbb{C} \) introduce

\[
A_0(\zeta) = \begin{pmatrix}
\frac{d}{d\zeta} \text{Ai}(\zeta) & e^{i\pi/3} \frac{d}{d\zeta} \text{Ai} \left( e^{-i\pi/3} \zeta \right) \\
\text{Ai}(\zeta) & e^{i\pi/3} \text{Ai} \left( e^{-i\pi/3} \zeta \right)
\end{pmatrix}.
\]  

(3.12)

Next assemble the model function

\[
A^{RH}(\zeta) = \begin{cases}
A_0(\zeta), & \text{arg} \ \zeta \in (0, \frac{2\pi}{3}), \\
A_0(\zeta) \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}, & \text{arg} \ \zeta \in \left( \frac{2\pi}{3}, \pi \right), \\
A_0(\zeta) \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}, & \text{arg} \ \zeta \in \left( -\frac{2\pi}{3}, 0 \right), \\
A_0(\zeta) \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}, & \text{arg} \ \zeta \in \left( -\pi, -\frac{2\pi}{3} \right).
\end{cases}
\]  

(3.13)

which solves the RHP depicted in Figure 5.

\[
\begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} \quad \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \quad \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \quad \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}
\]

**Figure 5.** The model RHP near \( z = b \) which can be solved explicitly using Airy functions.
we can always locally match the latter curves with the jump curves of the original RHP. Also these jumps are described by the same matrices as in the

\[ A_{RH}^{+}(\zeta) = A_{RH}^{-}(\zeta) \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} , \quad \arg \zeta = \frac{2\pi}{3} \]

\[ A_{RH}^{+}(\zeta) = A_{RH}^{-}(\zeta) \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} , \quad \arg \zeta = 0 \]

\[ A_{RH}^{+}(\zeta) = A_{RH}^{-}(\zeta) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} , \quad \arg \zeta = \pi \]

From the asymptotics of the Airy function (see for instance [4])

\[ A^{RH}(\zeta) = \frac{\zeta^{3/4}}{2\sqrt{\pi}} \begin{pmatrix} -1 & i \\ 1 & i \end{pmatrix} \left[ I + \frac{1}{48\zeta^{3/2}} \begin{pmatrix} 1 & 6i \\ 6i & -1 \end{pmatrix} + \frac{35}{4608\zeta^{6/2}} \begin{pmatrix} -1 & 12i \\ -12i & -1 \end{pmatrix} \right] + O(\zeta^{-9/2}) \]

\[ e^{-\frac{2}{3} \zeta^{3/2} \sigma_3} \] \quad (3.14)

The model function \( A^{RH}(\zeta) \) will now be used in the construction of the parametrix to the solution of the S-RHP in a neighborhood of \( z = b \). We proceed in two steps. First define

\[ \zeta(z) = \left( \frac{3N}{4} \right)^{2/3} \left( -2g(z) + V(z) + i \right)^{2/3}, \quad |z - b| < r. \hspace{1cm} (3.15) \]

This change of variables is locally conformal, since

\[ \zeta(z) = \left( \frac{Nq(b)}{2\sqrt{b}} \right)^{2/3} (z - b) \left[ 1 + \frac{2}{5} \left( \frac{q'(b)}{q(b)} - \frac{1}{2b} \right) (z - b) + O((z - b)^2) \right], \quad |z - b| < r \]

and it enables us to define the right parametrix \( U(z) \) near \( z = b \) by the formula

\[ U(z) = B_r(z)(-i\sqrt{\pi})A^{RH}(\zeta(z))e^{-\frac{2}{3} \zeta^{3/2}(z) \sigma_3 z^{-3/2}}, \quad |z - b| < r \quad (3.16) \]

with \( \zeta(z) \) as in (3.15) and the matrix multiplier

\[ B_r(z) = M(z) \zeta^{3/4}(z) \begin{pmatrix} -i & i \\ 1 & 1 \end{pmatrix} \zeta^{-\sigma_3/4}(z) = \left( \frac{\sqrt{b}}{2} \right)^{\sigma_3} \begin{pmatrix} -i & i \\ 1 & 1 \end{pmatrix} \left( \zeta(z) \frac{z}{z-b} \right)^{-\sigma_3/4} \]

\[ \times \zeta^{3/4}(z) \begin{pmatrix} i & 1 \\ 1 & 1 \end{pmatrix} D^{-\sigma_3}(z) \zeta^{3/2}(z) \begin{pmatrix} -i & i \\ 1 & 1 \end{pmatrix} \zeta^{-\sigma_3/4}(z). \hspace{1cm} (3.17) \]

We first notice that \( B_r(z) \) is analytic in a neighborhood of \( z = b \), since for \( z \in (b-r, b) \)

\[ (B_r(z))_+ = M_+(z) z^{\sigma_3/2} \begin{pmatrix} -i & i \\ 1 & 1 \end{pmatrix} \zeta^{-\sigma_3/4}(z) \]

\[ = M_-(z) \begin{pmatrix} 0 & z \sqrt{2} \\ -z/\sqrt{2} & 0 \end{pmatrix} z^{\sigma_3/2} \begin{pmatrix} -i & i \\ 1 & 1 \end{pmatrix} \zeta^{-\sigma_3/4}(z) e^{-i\frac{\pi}{4} \sigma_3} = (B_r(z))_-, \]

and by a direct computation

\[ B_r(b) = \left( \frac{\sqrt{b}}{2} \right)^{\sigma_3} \begin{pmatrix} -i & i \\ 1 & 1 \end{pmatrix} \left( \frac{Nq(b)}{2} \right)^{-\sigma_3/6}. \]

Hence by construction, the parametrix \( U(z) \) has jumps along the curves depicted in Figure [K] and we can always locally match the latter curves with the jump curves of the original RHP. Also these jumps are described by the same matrices as in the S-RHP, indeed with orientation as in Figure [B].
Let us explain the role of the left multiplier $B_r(z)$ in the definition (3.16). Observe that

$$B_r(z)\left(-\frac{i}{2}\right)^{\sigma_3/2}(z)\left(\begin{array}{cc}
-1
\end{array}\right) = M(z)z^{\sigma_3/2}$$

This relation together with the asymptotics (3.14) implies that,

$$U(z) = M(z)z^{\sigma_3/2} \left[ I + \frac{1}{48\zeta^{3/2}} \begin{array}{cc}
1
6i
\end{array} + \frac{35}{4608\zeta^{6/2}} \begin{array}{cc}
-1
12i
\end{array} + O(\zeta^{-9/2}) \right] z^{-\sigma_3/2}$$

$$= \left[ I + \frac{U_1(z)}{96\zeta^{3/2}} + \frac{35U_2(z)}{4608\zeta^{6/2}} + O(\zeta^{-9/2}) \right] M(z)$$

as $N \to \infty$ for any $\alpha > 1$ and $0 < r_1 \leq |z - b| \leq r_2 < \frac{b}{2}$ (so $|\zeta| \to \infty$). Here $U_k = (U_k^{ij})$ are given by

$$U_1^{11}(z) = \delta^2(z)\left(1 - \frac{3}{z}D^2(z) - 3zD^{-2}(z)\right) + \delta^{-2}(z)\left(1 + \frac{3}{z}D^2(z) + 3zD^{-2}(z)\right) = -U_1^{22}$$

$$U_1^{12}(z) = -\frac{ib}{4}\left(\delta^2(z) - \delta^{-2}(z) - \frac{3}{z}D^2(z)(\delta(z) - \delta^{-1}(z))^2 - 3zD^{-2}(z)(\delta(z) + \delta^{-1}(z))^2\right)$$
\[ U_1^{21}(z) = -\frac{4i}{b} \left( \delta^2(z) - \delta^{-2}(z) - \frac{3}{z}D^2(z)(\delta(z) + \delta^{-1}(z))^2 \right) - 3zD^{-2}(z)(\delta(z) - \delta^{-1}(z))^2 \]

and

\[
\begin{align*}
U_2^{11}(z) &= -1 + \delta^2(z) \left( \frac{3}{z}D^2(z) - 3zD^{-2}(z) \right) - \delta^{-2}(z) \left( \frac{3}{z}D^2(z) - 3zD^{-2}(z) \right) \\
U_2^{22}(z) &= -1 - \delta^2(z) \left( \frac{3}{z}D^2(z) - 3zD^{-2}(z) \right) + \delta^{-2}(z) \left( \frac{3}{z}D^2(z) - 3zD^{-2}(z) \right) \\
U_2^{12}(z) &= -\frac{ib}{4} \left( \frac{3}{z}D^2(z)(\delta(z) - \delta^{-1}(z))^2 - 3zD^{-2}(z)(\delta(z) + \delta^{-1}(z))^2 \right) \\
U_2^{21}(z) &= \frac{4i}{b} \left( \frac{3}{z}D^2(z)(\delta(z) + \delta^{-1}(z))^2 - 3zD^{-2}(z)(\delta(z) - \delta^{-1}(z))^2 \right).
\end{align*}
\]

Since the function \( \zeta(z) \) is of order \( N^{2/3} \) on the latter annulus and \( \delta(z), D(z) \) are bounded, equation (3.18) yields the matching relation between the model function \( U(z) \) and \( M(z) \),

\[ U(z) = (I + o(1))M(z), \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1, \quad 0 < r_1 \leq |z - b| \leq r_2 < \frac{b}{2} \]

which is crucial for the successful implementation of the nonlinear steepest descent method as we shall see later on. We also emphasize that the last estimation is uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). This is the reason for choosing the left multiplier \( B_r(z) \) in (3.16) in the form \( 34 \).

3.6. Construction of a parametrix at \( z = 0 \). Fix a small neighborhood \( V \) of the origin and observe that

\[
G(z) = 2g(z) - V(z) - l = \frac{b}{z} \int \sqrt{\frac{w - b}{w}q(w)dw} = 2\pi i - \frac{b}{z} \int 0 \sqrt{\frac{w - b}{w}q(w)dw} = 2\pi i - 2h_2(z)\sqrt{z}, \quad z \in V \cap \gamma^+, \quad 0 < \arg z \leq 2\pi
\]

where \( h_2(z) \) is analytic in \( V \) such that

\[ h_2(z) = e^{\frac{z}{2b}}q(0)\sqrt{b} \left[ 1 + \frac{1}{3} \left( \frac{q'(0)}{q(0)} - \frac{1}{2b} \right) z + O(z^3) \right], \quad z \to 0. \]

Similarly

\[
G(z) = -2g(z) + V(z) + l = 2\pi i + 2h_2(z)\sqrt{z}, \quad z \in V \cap \gamma^-, \quad 0 < \arg z \leq 2\pi
\]

and both stated local behaviors suggest to use the Bessel functions \( I_1(\zeta) \) and \( K_1(\zeta) \) in the construction of an edge point parametrix. This idea can be justified rigorously as follows. First we recall (cf. [4]) that the modified Bessel functions are unique independent solutions to Bessel’s equation

\[ z^2w'' + zw' - (z^2 + 1)w = 0 \]

satisfying the following asymptotic conditions as \( \zeta \to \infty \) and \( -\frac{\pi}{2} < \arg \zeta < \frac{3\pi}{2} \)

\[ I_1(\zeta) \sim \frac{e^\zeta}{\sqrt{2\pi \zeta}} \left( 1 - \frac{3}{8\zeta} - \frac{15}{64\zeta^2} + O(\zeta^{-3}) \right) + \frac{e^{-\zeta}e^{iz}}{\sqrt{2\pi \zeta}} \left( 1 + \frac{3}{8\zeta} - \frac{15}{64\zeta^2} + O(\zeta^{-3}) \right) \]
as well as for $-\frac{3\pi}{2} < \arg \zeta < \frac{\pi}{2}$

$$I_1(\zeta) \sim \frac{e^\zeta}{\sqrt{2\pi \zeta}} \left(1 - \frac{3}{8\zeta} - \frac{15}{64\zeta^2} + O(\zeta^{-3})\right) + \frac{e^{-i\pi}}{\sqrt{2\pi \zeta}} \left(1 + \frac{3}{8\zeta} - \frac{15}{64\zeta^2} + O(\zeta^{-3})\right).$$

On the other hand

$$K_1(\zeta) = \sqrt{\frac{\pi}{2\zeta}} e^{-\zeta} \left(1 + \frac{3}{8\zeta} - \frac{15}{64\zeta^2} + O(\zeta^{-3})\right), \quad \zeta \to \infty$$

which holds in a full neighborhood of infinity. Secondly $I_1(\zeta), K_1(\zeta)$ satisfy monodromy relations, valid on the entire universal covering of the punctured plane

$$I_1(e^{-i\pi}\zeta) = e^{-i\pi} I_1(\zeta), \quad K_1(e^{-i\pi}\zeta) = e^{i\pi} K_1(\zeta) + i\pi I_1(\zeta)$$

and finally the following expansions at the origin are valid

$$I_1(\zeta) = \frac{\zeta}{2} \left(1 + \frac{\zeta^2}{8} + O(\zeta^4)\right), \quad K_1(\zeta) = \frac{1}{\zeta} \left(1 + O(\zeta^2 \ln \zeta)\right), \quad \zeta \to 0.$$

Remembering the latter properties we now introduce the following matrix-valued function on the punctured plane $\zeta \in \mathbb{C}\setminus\{0\}$

$$P_{BE}(\zeta) = e^{-i\frac{\pi}{4}} \left(\begin{array}{c c}
I_1(2e^{-i\frac{\pi}{4}}\sqrt{\zeta}) & -iK_1(2e^{-i\frac{\pi}{4}}\sqrt{\zeta}) \\
-2\pi i \sqrt{\zeta}(I_1)(2e^{-i\frac{\pi}{4}}\sqrt{\zeta}) & -2\sqrt{\zeta}(K_1)(2e^{-i\frac{\pi}{4}}\sqrt{\zeta})
\end{array}\right), \quad 0 < \arg \zeta \leq 2\pi. \quad (3.21)$$

Using the behavior of $I_1(\zeta)$ and $K_1(\zeta)$ at infinity, we deduce

$$P_{BE}(\zeta) = \zeta^{-\sigma_3/4}(2\pi)^{-\sigma_3/2} \frac{1}{\sqrt{2}} \begin{pmatrix}
1 & -i \\
-1 & 1
\end{pmatrix} \left[ I + \frac{1}{16\sqrt{\zeta}} \begin{pmatrix}
-5i & -2 \\
-2 & 5i
\end{pmatrix} + \frac{3}{64\zeta} \begin{pmatrix}
-1 & -6i \\
6i & -1
\end{pmatrix}
\right] e^{-2i\sqrt{3}\zeta} \begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}, \quad \zeta \to \infty, \quad \frac{\pi}{3} < \arg \zeta < \frac{7\pi}{3} \quad (3.22)$$

and

$$P_{BE}(\zeta) = \zeta^{-\sigma_3/4}(2\pi)^{-\sigma_3/2} \frac{1}{\sqrt{2}} \begin{pmatrix}
1 & -i \\
-1 & 1
\end{pmatrix} \left[ I + \frac{1}{16\sqrt{\zeta}} \begin{pmatrix}
-5i & -2 \\
-2 & 5i
\end{pmatrix} + \frac{3}{64\zeta} \begin{pmatrix}
-1 & -6i \\
6i & -1
\end{pmatrix}
\right] e^{-2i\sqrt{3}\zeta} \begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}, \quad \zeta \to \infty, \quad -\frac{\pi}{3} < \arg \zeta < \frac{5\pi}{3}. \quad (3.23)$$

Let us now assemble the following model function

$$P_{BE}^{RH}(\zeta) = \begin{cases}
P_{BE}(\zeta) \begin{pmatrix}
1 & 0 \\
1 & 1
\end{pmatrix}, & \text{arg} \ \zeta \in (0, \frac{\pi}{3}), \\
P_{BE}(\zeta), & \text{arg} \ \zeta \in (\frac{\pi}{3}, \frac{5\pi}{3}), \\
P_{BE}(\zeta) \begin{pmatrix}
1 & 0 \\
-1 & 1
\end{pmatrix}, & \text{arg} \ \zeta \in (\frac{5\pi}{3}, 2\pi). 
\end{cases} \quad (3.24)$$

which solves the RHP depicted in Figure \[ \] 2.

More precisely, the function $P_{BE}^{RH}(\zeta)$ possess the following analytic properties.

- $P_{BE}^{RH}(\zeta)$ is analytic for $\zeta \in \mathbb{C}\setminus\{\text{arg} \ \zeta = 0, \frac{\pi}{3}, \frac{5\pi}{3}\}$
The following jumps hold
\[
\begin{align*}
\left( P_{BH}^R(\zeta) \right)_+ &= \left( P_{BH}^R(\zeta) \right)_- \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}, \quad \arg \zeta = \frac{\pi}{3} \\
\left( P_{BH}^R(\zeta) \right)_+ &= \left( P_{BH}^R(\zeta) \right)_- \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix}, \quad \arg \zeta = \frac{5\pi}{3}
\end{align*}
\]

And for the jump on the line \( \arg \zeta = 0 \) we notice that the monodromy relations imply
\[
\begin{align*}
I_1(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_+}) &= I_1(2e^{-i\frac{\pi}{2}}e^{-i\pi\sqrt{\zeta_-}}) = e^{-i\pi}I_1(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_-}) \\
(I_1)'(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_+}) &= (I_1)'(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_-})
\end{align*}
\]
and
\[
\begin{align*}
K_1(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_+}) &= K_1(2e^{-i\frac{\pi}{2}}e^{-i\pi\sqrt{\zeta_-}}) = e^{i\pi}K_1(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_-}) + i\pi I_1(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_-}) \\
(K_1)'(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_+}) &= (K_1)'(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_-}) - i\pi (I_1)'(2e^{-i\frac{\pi}{2}}\sqrt{\zeta_-}).
\end{align*}
\]
Therefore
\[
\left( P_{BE}(\zeta) \right)_+ = \left( P_{BE}(\zeta) \right)_- \begin{pmatrix} -1 & 1 \\ 0 & -1 \end{pmatrix}
\]
and hence
\[
\left( P_{BE}^R(\zeta) \right)_+ = \left( P_{BE}^R(\zeta) \right)_- \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \arg \zeta = 0.
\]

At the origin
\[
P_{BE}^R(\zeta) = \frac{e^{-i\frac{\pi}{2}}}{2\sqrt{\zeta}} \left[ \begin{pmatrix} 0 & 1 \\ 0 & 1 \end{pmatrix} + O(\zeta \ln \zeta) \right], \quad \zeta \to 0, \quad \frac{\pi}{3} < \arg \zeta < \frac{5\pi}{3}
\] (3.25)

and for the other sector we have to multiply the latter expansion with the correct multipliers from (3.24).

In order to determine the behavior of \( P_{BE}^R(\zeta) \) at infinity, we recall (3.22) and (3.23) as well as
\[
e^{-2i\sqrt{\zeta}\sigma_3} \begin{pmatrix} 1 & 0 \\ \pm 1 & 1 \end{pmatrix} e^{2i\sqrt{\zeta}\sigma_3} = \begin{pmatrix} 1 & 0 \\ \pm e^{4i\sqrt{\zeta}} & 1 \end{pmatrix}, \quad \frac{\pi}{3} < \arg \zeta < \frac{5\pi}{3}.
\]
However for those $\zeta$, we have $\text{Re}(4i\sqrt{\zeta}) < 0$, hence the given product approaches the identity exponentially fast as $\zeta \to \infty$. Together we have

$$P_{BE}^{RH}(\zeta) = \zeta^{-\sigma_3/4}(2\pi)^{-\sigma_3/2} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix} \left[ I + \frac{1}{16 \sqrt{\zeta}} \begin{pmatrix} -5i & -2 \\ -2 & 5i \end{pmatrix} \right] + \frac{3}{64 \zeta} \begin{pmatrix} -1 & -6i \\ 6i & -1 \end{pmatrix} + O(\zeta^{-3/2}) e^{-2i\sqrt{\zeta}\sigma_3}, \quad \zeta \to \infty$$ (3.26)

valid in a whole neighborhood of infinity.

The model function $P_{BE}^{RH}(\zeta)$ will now be used to construct the parametrix to the solution of the original $S$-RHP in a neighborhood of $z = 0$. We need again several steps. First define

$$\zeta(z) = e^{-i\pi} \left( \frac{N}{4} \right)^2 (2g(z) + V(z) + l - 2\pi i)^2, \quad |z| < r, \quad 0 < \arg \zeta \leq 2\pi.$$ (3.27)

This change of variables is locally conformal, since

$$\zeta(z) = \left( \frac{Nq(0)\sqrt{b}}{2} \right)^2 \left[ 1 + \frac{2}{3} \left( \frac{q'(0)}{q(0)} - \frac{1}{2b} \right) z + O(z^2) \right], \quad |z| < r$$

and it enables us to define the left parametrix $V(z)$ near $z = 0$ by the formula

$$W(z) = B_l(z) P_{BE}^{RH}(\zeta(z)) e^{2i\zeta^{1/2}(z)\sigma_3(-z)^{-\sigma_3/2}}, \quad |z| < r$$ (3.28)

with $\zeta(z)$ as in (3.26) and the matrix multiplier

$$B_l(z) = M(z)(-z)^{\sigma_3/2} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \zeta^{\sigma_3/4}(z)(2\pi)^{\sigma_3/2}.$$ 

Again $B_l(z)$ is analytic in a neighborhood of $z = 0$, for $z \in (0, r)$

$$(B_l(z))_+ = M_+(z)(-z)^{\sigma_3/2} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \zeta^{\sigma_3/4}(z)(2\pi)^{\sigma_3/2}$$

$$= M_-(z) \begin{pmatrix} 0 & z \\ -\frac{1}{z} & 0 \end{pmatrix} (-z)^{\sigma_3/2} e^{i\pi\sigma_3} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \zeta^{\sigma_3/4}(z) e^{-i\frac{3}{2}\sigma_3(2\pi)^{\sigma_3/2}}$$

$$= (B_l(z))_-$$

and with

$$\delta(z)(\zeta(z))^{-1/4} = \left( \frac{z}{\zeta(z)(z - b)} \right)^{1/4} = \left( \frac{4e^{i\pi}}{N^2 b^2 q(0)} \right)^{1/4} \left( 1 + O(z) \right), \quad z \to 0$$

we obtain from a direct computation

$$B_l(0) = \frac{1}{\sqrt{2}} \frac{\sqrt{b}}{2} \sigma_3 \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \frac{1}{4} \left( \frac{N^2 b^2 q(0)}{e^{i\pi}} \right)^{\sigma_3/4}.$$ 

Moreover the latter identity combined with (3.25), allows us to show that

$$W(z) = O(1), \quad z \to 0, \quad \frac{\pi}{3} < \arg z < \frac{5\pi}{3}$$

as well as

$$W(z) = O(z^{-1}), \quad z \to 0, \quad 0 < \arg z < \frac{\pi}{3}, \quad \frac{5\pi}{3} < \arg z < 2\pi,$$

which precisely matches the endpoint behavior of $S(z)$ in (3.30) and (3.31). On the other hand by construction, the parametrix $W(z)$ has jumps along the curves depicted in Figure 8 and we can always locally match the latter curves with the jump curves of the original RHP.
Also these jumps are described by the same matrices as in the S-RHP, indeed we have
\[
(-z)^{\sigma_3/2} e^{-2i \zeta^{1/2}(z) \sigma_3} \left( \begin{array}{cc} 1 & 0 \\ -1 & 1 \end{array} \right) e^{2i \zeta^{1/2}(z) \sigma_3} (-z)^{-\sigma_3/2} \begin{array}{c} 1 \\ -i \end{array} = \begin{array}{c} 1 \\ -i \end{array}, \quad z \in \mathcal{V} \cap \mathcal{V}^+_\gamma
\]
\[
(-z)^{\sigma_3/2} e^{-2i \zeta^{1/2}(z) \sigma_3} \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) e^{2i \zeta^{1/2}(z) \sigma_3} (-z)^{-\sigma_3/2} \begin{array}{c} 0 \\ -i \end{array} = \begin{array}{c} 0 \\ -i \end{array}, \quad z \in \mathcal{V} \cap (0, b)
\]
\[
(-z)^{\sigma_3/2} e^{-2i \zeta^{1/2}(z) \sigma_3} \left( \begin{array}{cc} 1 & 0 \\ -1 & 1 \end{array} \right) e^{2i \zeta^{1/2}(z) \sigma_3} (-z)^{-\sigma_3/2} \begin{array}{c} 1 \\ -i \end{array} = \begin{array}{c} 1 \\ -i \end{array}, \quad z \in \mathcal{V} \cap \mathcal{V}^- \gamma.
\]
Hence the ratio of \(S(z)\) with \(W(z)\) is locally analytic, i.e.
\[
S(z) = N_l(z)W(z), \quad 0 < |z| < \frac{b}{2}, \quad (3.29)
\]

The role of the left multiplier \(B_l(z)\) in (3.28) is the same as in the construction of the parametrix \(U(z)\), it provides us with the required asymptotic matching relation. With
\[
B_l(z)\zeta^{-\sigma_3/4}(z)(2\pi)^{-\sigma_3/2} \frac{1}{\sqrt{2}} \begin{array}{cc} 1 \\ -i \end{array} = M(z)(-z)^{\sigma_3/2}
\]
we deduce from (3.26)
\[
W(z) = M(z)(-z)^{\sigma_3/2} \left[ I + \frac{1}{16\sqrt{\zeta}} \begin{array}{cc} -5i & -2 \\ -2 & 5i \end{array} + \frac{3}{64\zeta} \begin{array}{cc} -1 & -6i \\ 6i & -1 \end{array} + O(\zeta^{-3/2}) \right] (-z)^{-\sigma_3/2}
\]
\[
= \left[ I + \frac{W_1(z)}{32\sqrt{\zeta}} + \frac{3W_2(z)}{64\zeta} + O(\zeta^{-3/2}) \right] M(z) \quad (3.30)
\]
as \(N \to \infty\) (hence \(|\zeta| \to \infty\)), for any \(\alpha > 1\) and \(0 < r_1 \leq |z| \leq r_2 < \frac{b}{2}\). The coefficients \(W_k = (W_k^{ij})\) are given by
\[
W_1^{11}(z) = -i\delta^2(z) \left( 5 - \frac{1}{z} D^2(z) - z D^{-2}(z) \right) - i\delta^{-2}(z) \left( 5 + \frac{1}{z} D^2(z) + z D^{-2}(z) \right)
\]
\[
= -W_1^{22}(z)
\]
\[
W_1^{12}(z) = \frac{b}{4} \left( -5(\delta^2(z) - \delta^{-2}(z)) + \frac{1}{z} D^2(z) (\delta(z) - \delta^{-1}(z))^2 
\right.
\]
\[
+ z D^{-2}(z) (\delta(z) + \delta^{-1}(z))^2
\]
\[
W_1^{21}(z) = \frac{4}{\delta} \left( -5(\delta^2(z) - \delta^{-2}(z)) + \frac{1}{z}D^2(z)(\delta(z) + \delta^{-1}(z))^2 \right)
\]

as well as
\[
\begin{align*}
W_2^{11}(z) &= -1 + \frac{3}{2}\delta^2(z) \left( \frac{1}{z}D^2(z) - zD^{-2}(z) \right) - \frac{3}{2}\delta^{-2}(z) \left( \frac{1}{z}D^2(z) - zD^{-2}(z) \right) \\
W_2^{22}(z) &= -1 - \frac{3}{2}\delta^2(z) \left( \frac{1}{z}D^2(z) - zD^{-2}(z) \right) + \frac{3}{2}\delta^{-2}(z) \left( \frac{1}{z}D^2(z) - zD^{-2}(z) \right) \\
W_2^{21}(z) &= \frac{-ib}{4} \left( \frac{3}{2z}D^2(z)(\delta(z) - \delta^{-1}(z))^2 - \frac{3}{2}zD^{-2}(z)(\delta(z) + \delta^{-1}(z))^2 \right) \\
W_2^{12}(z) &= \frac{-4i}{b} \left( \frac{3}{2z}D^2(z)(\delta(z) + \delta^{-1}(z))^2 - \frac{3}{2}zD^{-2}(z)(\delta(z) - \delta^{-1}(z))^2 \right).
\end{align*}
\]

Since the function \( \zeta(z) \) is of order \( N^2 \) on the latter annulus and \( \delta(z), D(z) \) are bounded, equation (3.29) provides us with the following matching relation between \( W(z) \) and \( M(z) \)
\[
W(z) = (I + o(1))M(z), \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1, \quad 0 < r_1 \leq |z| \leq r_2 < \frac{b}{2}.
\] (3.31)

At this point we can use the model functions \( M(z), U(z) \) and \( W(z) \) to employ the next transformation.

3.7. Third transformation of the RHP - ratio problem. In this transformation we put
\[
R(z) = S(z) \begin{cases} (W(z))^{-1}, & |z| < r_1, \\
(U(z))^{-1}, & |z - b| < r_2, \\
(M(z))^{-1}, & |z| > r_1, |z - b| > r_2 \end{cases}
\] (3.32)

with \( 0 < r_2 < \frac{b}{2} \) and \( 0 \leq r_1 < \min \{ \frac{b}{2}, \frac{\pi}{b} \} \). The reason for choosing the latter radius in this explicit \( t \)-dependent form arises from the analyticity of the potential \( V(z) \), which is holomorphic in the strip \( \Delta_t \). Moreover the set of its branch points \( \Omega_t \) is given by
\[
\Omega_t = \left\{ \frac{n\pi}{\tau} : n \in \mathbb{Z}\setminus\{0\} \right\}.
\]

Hence we need to choose a neighborhood of the origin in \( \mathbb{C} \setminus \Omega_t \) which does not include any of the branch points. With \( C_{t,b} \) denoting the clockwise oriented circles shown in Figure 9, the ratio-function \( R(z) \) solves the following RHP

![Figure 9: The jump graph for the ratio function \( R(z) \)](image)

- \( R(z) \) is analytic for \( z \in \mathbb{C}\setminus\{C_{t,b} \cup \Gamma \cup (b + r_2, \infty)\} \) with \( \Gamma = \hat{\gamma}_+ \cup \hat{\gamma}_- \)
For the jumps, along the infinite branches \((b + r_2, \infty)\)

\[
R_+ (z) = R_-(z)M(z) \begin{pmatrix}
1 & ze^{N(g_+ + g_- - V - I)} \\
0 & 1
\end{pmatrix} (M(z))^{-1},
\]

on the upper lense boundary \(\hat{\gamma}_+\) respectively lower lense boundary \(\hat{\gamma}_-\)

\[
R_+ (z) = R_-(z)M(z) \begin{pmatrix}
1 & ze^{-N\gamma} \\
0 & 1
\end{pmatrix} (M(z))^{-1}, \quad z \in \hat{\gamma}_+
\]

\[
R_+ (z) = R_-(z)M(z) \begin{pmatrix}
1 & ze^{N\gamma} \\
0 & 1
\end{pmatrix} (M(z))^{-1}, \quad z \in \hat{\gamma}_-
\]

and on the clockwise oriented circles \(C_{t,b}\)

\[
R_+ (z) = R_-(z) \begin{cases}
W(z) (M(z))^{-1}, & |z| = r_1, \\
U(z) (M(z))^{-1}, & |z - b| = r_2.
\end{cases}
\]

In a neighborhood of infinity, we have \(R(z) \to I\).

Here, by construction, the function \(R(z)\) has no jumps inside of \(C_t\) and \(C_b\) and across the line segment in between. Also \(R(z)\) is bounded at \(z = 0\) and \(z = b\), which follows from (3.18) and (3.29). It is now important to recall the previously stated behavior of the jump matrices as \(N \to \infty\) which are valid for any \(\alpha > 1\) such that \(0 \leq \tau \leq 1 - \varepsilon < 1\). In fact, on the half ray \((b + r_2, \infty)\) the stated jump matrices approach the identity matrix. Also in virtue of (3.19) the same holds true on the circle \(C_b\), more precisely with \(G_R\) denoting the jump matrix in the latter ratio-RHP

\[
||G_R - I||_{L^2(\gamma, \infty)} \leq \frac{\hat{c}}{N}, \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1
\]

(3.33)

with a constant \(\hat{c} > 0\) whose value is not important. For the lense boundaries we use the local identities

\[
G(z) = 2\pi i \mp 2h_2(z)\sqrt{z}, \quad z \in \mathcal{V} \cap \gamma^\pm.
\]

They imply

\[
\sup_{z \in \gamma^+ \cup \gamma^-} |G_R(z) - I| = \sup_{z \in (\gamma^+ \cup \gamma^-) \cap C_t} |G_R(z) - I| = O(te^{-cNt^{-1/2}}), \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1
\]

(3.34)

and since

\[
\frac{N}{\sqrt{t}} = \sqrt{N\alpha} \to \infty \quad \text{as} \quad N \to \infty \quad \text{for any} \quad \alpha > 1: \quad 0 \leq \tau \leq 1 - \varepsilon < 1,
\]

we see that the contributions arising from the lenses decay exponentially fast. In order to estimate \(G_R\) on the circle \(C_t\), we use (3.30)

\[
\sup_{z \in C_t} \left| G_R(z) - I - \frac{W_1(z)}{32\sqrt{\gamma}(z)} \right| = O\left( \frac{t}{N^2} \right) = O(\tau N^{-1}), \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1.
\]

(3.35)

This estimation holds since (3.30) extends to a full asymptotic series of the form

\[
G_R(z) - I = \sum_{k=1}^\infty \bar{W}_k(z)N^{-k},
\]

(3.36)

valid as long as \(N^2|z| \to \infty\). However for \(z \in C_t\)

\[
\frac{1}{N^2|z|} = O(\tau N^{-1}) \quad \text{as} \quad N \to \infty \quad \text{for any} \quad \alpha > 1: \quad 0 \leq \tau \leq 1 - \varepsilon < 1,
\]
so (3.36) holds in particular for \( z \in C_t \) and since \( \tilde{W}_k(z) \) has a pole of order at most \( \left\lfloor \frac{k+1}{2} \right\rfloor \) at the origin, we obtain (3.35).

From the local expansions

\[
D^2(z) = -z \left( 1 + O \left( \sqrt{z} \right) \right), \quad \delta^2(z) = -i \sqrt{b} \sqrt{z} \left( 1 + O(z) \right), \quad z \to 0, \quad z \in \mathbb{C} \setminus [0, b]
\]

we now evaluate the residue of \( \tilde{W}_1(z) \) at the origin

\[
B = \text{res}_{z=0} \tilde{W}_1(z) = \text{res}_{z=0} \left( \frac{NW_1(z)}{32 \sqrt{\zeta(z)}} \right) = \frac{3}{16q(0)} \left( \frac{b}{4} \right)^{\sigma_3/2} \left( \frac{1}{e^{i \frac{\pi}{2}} - 1} \right) \left( \frac{b}{4} \right)^{-\sigma_3/2}.
\]

Hence we can rewrite (3.35) as

\[
\sup_{z \in C_t} \left| G_R(z) - I - \frac{B}{Nz} \right| = O(N^{-1}), \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1, \quad (3.37)
\]

however

\[
\sup_{z \in C_t} \left| \frac{B}{Nz} \right| = O(\tau), \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1,
\]

so \( G_R(z) - I \) is not uniformly close to zero on \( C_t \) as \( N \to \infty \) for all \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). To overcome this difficulty we employ our final transformation.

### 3.8. Fourth and final transformation of the RHP

Since \( \det B = \text{trace} B = 0 \), we see that the matrix function \( I + \frac{B}{Nz} \) is unimodular for any \( z \in \mathbb{C} \setminus \{0\} \), in fact

\[
\left( I + \frac{B}{Nz} \right)^{-1} = I - \frac{B}{Nz}, \quad z \in \mathbb{C} \setminus \{0\}.
\]

We introduce

\[
Q(z) = \begin{cases} 
R(z), & |z| \leq r_1, \\
R(z) \left( I + \frac{B}{Nz} \right)^{-1}, & |z| > r_1.
\end{cases} \quad (3.38)
\]

and are lead to the following RHP

- \( Q(z) \) is analytic for \( z \in \mathbb{C} \setminus \{ C_{t,b} \cup \hat{\Gamma} \cup (b + r_2, \infty) \} \)
- With \( G_Q \) denoting the jump matrix in the \( Q \)-RHP we have
  \[
  G_Q(z) = \begin{cases} 
  G_R(z) \left( I + \frac{B}{Nz} \right)^{-1}, & z \in C_t \\
  \left( I + \frac{B}{Nz} \right) G_R(z) \left( I + \frac{B}{Nz} \right)^{-1}, & z \in C_b \cup \hat{\Gamma} \cup (b + r_2, \infty)
  \end{cases}
  \]
- As \( z \to \infty \), we have \( Q(z) \to I \)

In the stated problem all jump matrices approach the identity matrix as \( N \to \infty \) for any \( \alpha > 1 \) such that \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). More precisely with \( \Sigma_Q \) denoting the underlying contour

\[
\| G_Q - I \|_{L^2 \cap L^\infty(\Sigma_Q)} \leq \frac{c}{N}, \quad N \to \infty, \quad 0 \leq \tau \leq 1 - \varepsilon < 1 \quad (3.39)
\]

with a constant \( c > 0 \) whose value is not important. The latter estimation enables us to solve the \( Q \)-RHP iteratively.
3.9. Solution of the RHP for $Q(z)$ via iteration. The stated RHP for the function $Q(z)$

- $Q(z)$ is analytic for $z \in \mathbb{C} \setminus \Sigma_Q$.
- Along the contour depicted in Figure 9,
  $$Q_+(z) = Q_-(z)G_Q(z), \quad z \in \Sigma_Q.$$
- As $z \to \infty$, we have $Q(z) = I + O(z^{-1})$

is equivalent to the singular integral equation

$$Q_-(z) = I + \frac{1}{2\pi i} \int_{\Sigma_Q} Q_-(w)(G_Q(w) - I) \frac{dw}{w-z}$$

(3.40)

and by standard arguments (see [18]), combined with arguments from [10], we know that for sufficiently large $N$ and any $\alpha > 1 : 0 \leq \tau \leq 1 - \varepsilon < 1$, the relevant integral operator is contracting and equation (3.40) can be solved iteratively in $L^2(\Sigma_Q)$. Moreover, its unique solution satisfies the important estimation

$$\|Q_--I\|_{L^2(\Sigma_Q)} \leq \frac{c}{N}, \quad N \to \infty \quad \text{for any } \alpha > 1 : 0 \leq \tau \leq 1 - \varepsilon < 1.$$ (3.41)

We are now ready to determine the large $N$ asymptotics of the normalizing constants $h_{N,t}$. To this end notice that for $z \in \mathbb{C} \setminus \Sigma_Q$

$$Q(z) = I + \frac{i}{2\pi \sigma_3} \int_{\Sigma_Q} Q_-(w)(G_Q(w) - I) dw + O(z^{-2}), \quad z \to \infty$$

(3.42)

and also as $N \to \infty$ for any $\alpha > 1 : 0 \leq \tau \leq 1 - \varepsilon < 1$ (following from (3.39) and (3.41) as well as the previous discussion about exponentially small contributions)

$$\int_{\Sigma_Q} Q_-(w)(G_Q(w) - I) dw = \int_{C_t} (G_Q(w) - I) dw + \int_{C_b} (G_Q(w) - I) dw + O(N^{-2}).$$ (3.43)

4. Asymptotics of $h_{N,t}$ - proof of theorem 1.3

We go back to (3.1)

$$h_{N,t} = -2\pi i \left(Y_1^{(N)}\right)_{12}$$

and recall that

$$Y_1^{(N)} = \lim_{z \to \infty} \left(z \left(Y^{(N)}(z)z^{-N\sigma_3} - I\right)\right).$$ (4.1)

Now recall the sequence of transformations

$Y(z) \equiv Y^{(N)}(z) \mapsto T(z) \mapsto S(z) \mapsto R(z) \mapsto Q(z)$

and combine it with the expansion

$$e^{N\left(g(z)-\frac{1}{2}\sigma_3\right)z^{-N\sigma_3}} = e^{-\frac{N\sigma_3}{2}} \int_{0}^{b} w\psi(w) dw + O(z^{-2}), \quad z \to \infty.$$

This gives us for (1.1)

$$Y_1^{(N)} = \lim_{z \to \infty} \left(z \left(e^{\frac{N\sigma_3}{2}Q(z)}\left(I + \frac{B}{Nz}\right)M(z)e^{N\left(g(z)-\frac{1}{2}\sigma_3\right)z^{-N\sigma_3} - I}\right)\right)$$
In view of (3.43), we will now compute the contribution arising from the circle \( N \) as \( z \) valid as \( h \rightarrow \infty \) hence \( N \) as \( z \) along the circle boundary \( C \) \( z \rightarrow \infty \). Now use the local expansions which is again uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \) and hence (compare (3.42))

\[
\int_{C_{b}} Q_{-}(w)(G_{Q}(w) - I)dw = \frac{1}{96} \int_{C_{b}} \left( U_{11}(w) U_{12}(w) \right) \frac{dw}{\zeta^{3/2}(w)} + O \left( N^{-2} \right)
\]

Now use the local expansions

\[
U_{11}^{1}(z) = -\frac{5\sqrt{b}}{\sqrt{z - b}} \left( 1 + \frac{3}{2b} (z - b) + O \left( (z - b)^{2} \right) \right),
\]

\[
U_{12}^{1}(z) = \frac{5ib\sqrt{b}}{4\sqrt{z - b}} \left( 1 + \frac{91}{10b} (z - b) + O \left( (z - b)^{2} \right) \right),
\]

\[
U_{11}^{2}(z) = -\frac{20i}{\sqrt{b\sqrt{z - b}}} \left( 1 - \frac{1}{2b} (z - b) + O \left( (z - b)^{2} \right) \right),
\]

valid as \( z \rightarrow b \), and with (3.15) compute the relevant line integral via residue theorem. We obtain, as \( N \rightarrow \infty \),

\[
\int_{C_{b}} Q_{-}(w)(G_{Q}(w) - I)dw = -\frac{2\pi i}{96 Nq(b)} \left( \frac{21}{35} \left[ -3q'(b)q(b) - \frac{3}{b} \right] - \frac{ib}{2} \left[ -3q'(b)q(b) + \frac{47}{b} \right] \right)
\]

\[
+ O \left( N^{-2} \right)
\]

which is uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). For the remaining line integral along the circle boundary \( C_{t} \) recall (3.30) and (3.37) and deduce, as \( N \rightarrow \infty \)

\[
\int_{C_{t}} Q_{-}(w)(G_{Q}(w) - I)dw = \int_{C_{t}} \left( G_{R}(w) - I - \frac{B}{Nw} \right) \left( I - \frac{B}{Nw} \right) dw + O \left( N^{-2} \right) \quad (4.2)
\]

which is again uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). Now from (3.30), as \( z \rightarrow 0 \),

\[
W_{11}^{1}(z) = \frac{3\sqrt{b}}{\sqrt{z}} \left( 1 - \frac{3z}{2b} + O \left( z^{2} \right) \right), \quad W_{12}^{1}(z) = \frac{3ib\sqrt{b}}{4\sqrt{z}} \left( 1 + \frac{35z}{6b} + O \left( z^{2} \right) \right)
\]

\[
W_{11}^{2}(z) = \frac{3ib\sqrt{b}}{b\sqrt{z}} \left( 1 + \frac{z}{2b} + O \left( z^{2} \right) \right),
\]

hence

\[
\frac{W_{1}(z)}{32\sqrt{\zeta}(z)} - \frac{B}{Nz} = -\frac{1}{3N} \left( \frac{q'(0)}{q(0)} - \frac{1}{2b} \right) B + \frac{1}{2Nb} \left( \frac{3}{16q(0)} \right) \left( \frac{b}{4} \right)^{3/2} \left( \frac{1}{3} \right) \left( \frac{b}{4} \right)^{-3/2}
\]

\[
+ O \left( zN^{-1} \right), \quad z \rightarrow 0.
\]
Back to (4.2), as \( N \to \infty \) therefore
\[
\int_{C_t} Q_{-}(w)(G_{Q}(w) - I) \, dw = O\left( N^{-2} \right),
\]
which is uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). At this point we summarize our computations
\[
e^{-\frac{N}{2} \sigma_3} Y_1^{(N)} e^{\frac{N}{2} \sigma_3} = -N \sigma_3 \int_0^b w \psi(w) \, dw + \frac{b}{4} \left( -\frac{1}{16} \frac{\delta}{\bar{\tau}} + 1 \right) + \frac{B}{N}
\]
\[
+ \frac{1}{96} \frac{b}{Nq(b)} \left( \frac{6(q'(b))}{q(b)} - \frac{\delta}{\bar{\tau}} \right) \frac{\frac{b}{2}}{2} \left[ -3 \frac{q'(b)}{q(b)} - \frac{\delta}{\bar{\tau}} \right] - 6\left( \frac{q'(b)}{q(b)} - \frac{\delta}{\bar{\tau}} \right) + O\left( N^{-2} \right),
\]
which implies, as \( N \to \infty \),
\[
\left( Y_1^{(N)} \right)_{12} = i e^{\frac{N}{4}} \left( \frac{b}{4} \right)^2 \left[ 1 + \frac{v}{N} + O\left( N^{-2} \right) \right], \quad 0 \leq \tau \leq 1 - \varepsilon < 1,
\]
with (compare (1.20))
\[
v = \frac{3}{4bq(0)} - \frac{q(b)}{4q^2(b)} + \frac{47}{12bq(b)}.
\]
All we need to do now is recall (3.1), the connection formula \( h_N = 2t^{2N+2} h_{N,t} \) and combine it with Stirling’s approximation
\[
N! = \left( \frac{N}{e} \right)^N \sqrt{2\pi N} \left( 1 + \frac{1}{12N} + O\left( N^{-2} \right) \right), \quad N \to \infty.
\]
This gives, as \( N \to \infty \),
\[
\frac{h_N}{(N!)^2} = \frac{N}{8} \tau^{2N+2} b^2 \exp \left[ N(l+2) + \frac{v}{N} - \frac{1}{6N} + \varepsilon_N(\tau) \right]
\]
(4.3)
which is uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \), thus proving Theorem 1.3

Remark: At this point it is useful to compare the latter expansion to the estimation (1.28) derived in [3]. We obtain from the connection \( h_N^\alpha = (\alpha - 1)^{2N+1} h_N \) and (1.30), that, as \( N \to \infty \),
\[
\ln \left[ \frac{h_N^\alpha}{(N!)^2} \right] = (2N + 1) \ln(1 - \tau) + N(l + 2) + \ln \left( \frac{4}{8} \right) + 2 \ln b + \frac{v}{N} - \frac{1}{6N} + \varepsilon_N(\tau)
\]
(4.4)
uniformly with respect to \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). Also, as a consequence of the Riemann-Hilbert analysis presented in the last subsections, the estimation
\[
|\varepsilon_N| \leq \frac{c}{(N + 1)^2}, \quad c > 0
\]
on the error term \( \varepsilon_N(\tau) \), can in fact be extended to a full asymptotic series in reciprocal integer powers of \( N \) which is also uniform with respect to the parameter \( 0 \leq \tau \leq 1 - \varepsilon < 1 \). Now choose \( \alpha \) from any compact subset of the set (1.16) and let \( N \to \infty \), i.e. \( t \to \infty \). In this limit, Proposition 2.22 implies with 2.50,
\[
b = \frac{4}{1 - \tau} \left( 1 - \frac{1}{2N} + \frac{\zeta(3/2)}{8\sqrt{\pi(r-1)} N^{3/2}} + O\left( N^{-5/2} \right) \right), \quad N \to \infty, \quad r = \frac{\alpha + 1}{\alpha - 1}
\]
which extends to a full asymptotic series in reciprocal half-integer powers of $N$, the error terms being uniform on any compact subset of the set (1.16). Also via (2.21) and (2.20), as $N \to \infty,$

$$l = 4(1 - \ln 2) - \frac{3b}{2}(1 - \tau) + 2 \ln b - \frac{2}{N}(1 - \ln 2) - \frac{\ln(2bN\tau)}{N} + O\left(N^{-5/2}\right)$$

and which can also be extended to a full asymptotic series in reciprocal half-integer powers of $N$. Combining the last two expansions,

$$l = -2 - 4 \ln 2 + 2 \ln \left(\frac{4}{1 - \tau}\right) - \frac{\ln(2N)}{N} + \frac{\ln(\alpha - 1)}{N} - \frac{\zeta(3/2)}{2 \sqrt{\pi(r - 1)N^{3/2}}} + \frac{1}{4N^2} + O\left(N^{-5/2}\right).$$

and since from (2.14), as $N \to \infty$

$$v = \frac{7}{6} + O\left(N^{-1/2}\right),$$

we can go back to (4.4) and derive

$$\ln \left[\frac{h_N}{(N!)^2}\right] = -\frac{\zeta(3/2)}{2 \sqrt{\pi(r - 1)N^{1/2}}} + \frac{1}{4N^2} + O\left(N^{-3/2}\right), \quad N \to \infty \quad (4.5)$$

which is uniform on any compact subset of the set (1.16). The last estimation agrees with (1.23) and as we have seen, extends to a full asymptotic series in reciprocal half-integer powers of $N$.

As a first step in the computation of the $N$ independent leading term $C$ in the large $N$ expansion (1.15) of $Z_N$, we use the Toda equation.

5. Toda Equation and the Structure of the Constant Factor

We use the Toda equation as written in (1.13),

$$(\ln \tau_N)'' = \frac{h_N}{h_{N-1}} = \frac{h_N^0}{(\alpha - 1)2h_{N-1}^0}, \quad (') = \frac{d}{d\alpha}.$$ 

From (4.3) and our discussion thereafter, as $N \to \infty,$

$$\ln \left[\frac{h_N^0}{(N!)^2}\right] = -\frac{\zeta(3/2)}{2 \sqrt{\pi(r - 1)N^{1/2}}} + \frac{1}{4N^2} + \frac{c_1(\alpha)}{N^{3/2}} + \frac{c_2(\alpha)}{N^2} + O\left(N^{-5/2}\right)$$

with some constants $c_i(\alpha)$ whose precise form is not important for us. Hence

$$\ln \left[\frac{h_N^0}{N^2h_{N-1}^0}\right] = -\frac{\zeta(3/2)}{4 \sqrt{\pi(r - 1)N^{3/2}}} - \frac{1}{4N^2} + O\left(N^{-5/2}\right)$$

and after exponentiating the latter expansion, as $N \to \infty$

$$(\ln \tau_N)'' = \frac{N^2}{(\alpha - 1)^2} \left(1 + \frac{\zeta(3/2)}{4 \sqrt{\pi(r - 1)N^{3/2}}} - \frac{1}{4N^2} + O\left(N^{-5/2}\right)\right)$$

$$= -N^2(\ln(\alpha - 1))'' - \sqrt{N} \frac{\zeta(3/2)}{\sqrt{2\pi}} (\sqrt{\alpha - 1})'' + \frac{1}{4} (\ln(\alpha - 1))'' + O\left(N^{-1/2}\right),$$

where the error term is uniform on any compact subset of the set (1.16). Back to (4.14), we have therefore shown that

$$(\ln Z_N)'' = N^2 \left(\ln \left(\frac{\alpha + 1}{2}\right)\right)'' - \sqrt{N} \frac{\zeta(3/2)}{\sqrt{2\pi}} (\sqrt{\alpha - 1})'' + \frac{1}{4} (\ln(\alpha - 1))'' + O\left(N^{-1/2}\right). \quad (5.1)$$

On the other hand from (1.14) combined with (4.3),

$$\ln Z_N = \ln C + N^2 \ln \left(\frac{\alpha + 1}{2}\right) - \sqrt{N} \frac{\zeta(3/2)}{\sqrt{2\pi}} (\sqrt{\alpha - 1}) + \frac{1}{4} \ln N + O\left(N^{-1/2}\right),$$
where $C > 0$ depends in general on $\alpha$, but not on $N$. Thus, comparing the latter with (5.1), we conclude

$$\ln C = \frac{1}{4} (\ln(\alpha - 1))'' + O \left( N^{-1/2} \right).$$

Integrating this expansion, we get

$$\ln C = \frac{1}{4} \ln(\alpha - 1) + d(N)\alpha + c(N) + O \left( N^{-1/2} \right)$$

with some numbers $d(N)$ and $c(N)$ which are independent of $\alpha$. Now choose any distinct $\alpha_1, \alpha_2$ from (1.16) and derive

$$\ln C(\alpha_1) - \ln C(\alpha_2) = \frac{1}{4} \ln(\alpha_1 - 1) - \frac{1}{4} \ln(\alpha_2 - 1) + d_1(N)(\alpha_1 - \alpha_2) + O \left( N^{-1/2} \right),$$

which shows that the limit

$$\lim_{N \to \infty} d(N) = d$$

exists and therefore also the limit

$$\lim_{N \to \infty} c(N) = c.$$ 

Taking the limit $N \to \infty$ in (5.2), we obtain

$$\ln C = \frac{1}{4} \ln(\alpha - 1) + d\alpha + c,$$

and summarize (see (1.17))

**Proposition 5.1.** The constant factor $C$ in asymptotic formula (1.15) has the form

$$C = (\alpha - 1)^{1/4} e^{d\alpha + c}. \tag{5.3}$$

In light of the last proposition we now have to compute the remaining two universal constants $c$ and $d$. This will be done by studying two regimes of the double scaling parameter $t = \frac{N}{\alpha}$. First, we are interested in the behavior of the partition function $Z_N$ as $N \to \infty$ and $t$ remains bounded.

### 6. The double scaling limit of the partition function

We start with the observation that

$$\lim_{N \to \infty} w_t(x) = xe^{-Nx},$$

which in particular implies

$$w_t(x) \sim xe^{-Nx} \equiv w_0(x), \quad t \to 0.$$ 

The limiting orthogonal polynomials are the normalized (and rescaled) Laguerre polynomials (cf. [1])

$$p_n,0(x) = \lim_{t \to 0} p_n,t(x) = \frac{(-1)^n n!}{N^n} L_n^{(1)}(Nx)$$

for which

$$h_{n,t} \sim \int_0^{\infty} (p_n,0(x))^2 w_0(x) \, dx = \frac{(n!)^2}{N^{2n+2}} \int_0^{\infty} \left( L_n^{(1)}(x) \right)^2 xe^{-x} \, dx = \frac{(n!)^2 (n+1)}{N^{2n+2}} \equiv h_{n,0}, \quad t \to 0.$$ 

Let us introduce the abbreviation

$$\sigma_{N,t} = N^{N(N+1)} \prod_{k=0}^{N-1} \frac{h_{k,t}}{(k!)^2}, \tag{6.1}$$
which satisfies
\[
\lim_{N \to \infty} \sigma_{N,t} = N^{N(N+1)} \prod_{k=0}^{N-1} \frac{h_{k,0}}{(k!)^2} = N!
\] (6.2)

and which relates to the partition function \(Z_N\) via the identity
\[
Z_N = \left(\frac{\alpha^2 - 1}{2\alpha}\right)^{N^2} \left(\frac{2}{\alpha}\right)^N \sigma_{N,t}.
\] (6.3)

We will now evaluate (6.1) by using (4.3), in other words
\[
\sigma_{N,t} = N^{N(N+1)} h_{0,t} \prod_{k=1}^{N-1} \frac{h_{k,t}}{(k!)^2} = N^2 h_{0,t} \left(\frac{\alpha}{2}\right)^{N-1} \alpha^{N^2-1} \prod_{k=1}^{N-1} \frac{h_k}{(k!)^2}
\]
\[
= N^2 h_{0,t} (N-1)! \exp \left[ \sum_{k=1}^{N-1} \left( 2 \ln \left(\frac{b}{4}\right) + k(l+2) + \frac{v - \frac{7}{6}}{k} + 1 + \varepsilon_k(\tau) \right) \right]
\]
\[
= \hat{C}_0 N^2 h_{0,t} N! \exp \left[ \sum_{k=1}^{N-1} \left( 2 \ln \left(\frac{b}{4}\right) + k(l+2) + \frac{v - \frac{7}{6}}{k} \right) \right] (1 + O(N^{-1})),
\]
valid as \(N \to \infty\), where the error term is uniform with respect to the parameter \(0 \leq \tau \leq 1 - \varepsilon < 1\) and with a universal, i.e. \(N\) and \(\tau\) independent constant \(\hat{C}_0 > 0\). Now use (1.8) and derive
\[
h_{0,t} = \int_0^\infty (p_{0,t}(x))^2 w_t(x) \, dx = \hat{c}_0 \int_0^\infty w_t(x) \, dx = \frac{\hat{c}_0}{N^2(1 - \tau^2)}
\]
with another universal constant \(\hat{c}_0 > 0\). Back to the previous expansion for \(\sigma_{N,t}\), as \(N \to \infty\)
\[
\sigma_{N,t} = \frac{\hat{c}_0 N!}{1 - \tau^2} \exp \left[ \sum_{k=1}^{N-1} \left( 2 \ln \left(\frac{b}{4}\right) + k(l+2) + \frac{v - \frac{7}{6}}{k} \right) \right] (1 + O(N^{-1}))
\] (6.4)
which is uniform with respect to the parameter \(0 \leq \tau \leq 1 - \varepsilon < 1\). In order to determine the constant \(C_0\), we will now evaluate the sums in (6.4) in the double scaling limit \(N,\alpha \to \infty\) with \(0 \leq t \leq t_0\) and then compare the result with (6.2).

For the sums, use Euler’s summation formula
\[
\sum_{k=1}^{N-1} g(k) = \int_1^N g(x) \, dx + \int_1^{N-1} P_1(x) g'(x) \, dx + \frac{1}{2} (g(N-1) + g(1)),
\] (6.5)
which holds for a differentiable function \(g : \mathbb{R} \to \mathbb{R}\) with the Bernoulli polynomial \(P_1(x) = x - \lfloor x \rfloor - \frac{1}{2}\). First via (2.4), as \(N,\alpha \to \infty\),
\[
\sum_{k=1}^{N-1} 2 \ln \left(\frac{b}{4}\right) = 2t + \int_0^t I(8x) \frac{dx}{x} + O(N^{-1}),
\]
where the error term is uniform on any finite interval $0 \leq t \leq t_0$. Secondly via \eqref{2.21},

$$
\sum_{k=1}^{N-1} k(l + 2) = N \left[ -t + \frac{2}{t} \int_0^t \left( J(8x) - (1 - \ln 2) \right) dx - \frac{2}{t} \int_0^t I(8x) dx + \frac{1}{t} \int_0^t \ln S(4x) dx \right]
$$

$$
+ t - \frac{3}{2} t^2 - 2 t I(8t) - \frac{1}{2} I^2(8t) - \frac{3}{4} I(8t) - \frac{1}{2} \int_0^t I^2(8x) \frac{dx}{x}
$$

$$
+ 2 \int_0^t J'(8x) \left( 4 + \frac{2}{x} I(8x) \right) dx + J(8t) - (1 - \ln 2) + \frac{1}{2} \ln S(4t) + O \left( N^{-1} \right)
$$

and from \eqref{2.14},

$$
\sum_{k=1}^{N-1} \frac{v - \frac{2}{k}}{k} = O \left( N^{-1} \right)
$$

as $N, \alpha \to \infty$, where the error terms are uniform on any finite interval $0 \leq t \leq t_0$. We go back to \eqref{6.3}, as $N, \alpha \to \infty$,

$$
\sigma_{N,t} = C_0 \frac{N!}{e^{N\Phi(t) + \Psi(t)}} \left( 1 + O \left( N^{-1} \right) \right), \quad 0 \leq t \leq t_0 \tag{6.6}
$$

with

$$
\Phi(t) = -t + \frac{2}{t} \int_0^t \left( J(8x) - (1 - \ln 2) \right) dx - \frac{2}{t} \int_0^t I(8x) dx + \frac{1}{t} \int_0^t \ln S(4x) dx \tag{6.7}
$$

and

$$
\Psi(t) = 3t - \frac{3}{2} t^2 - 2 t I(8t) - \frac{1}{2} I^2(8t) - \frac{3}{4} I(8t) - \frac{1}{2} \ln S(4t) - \left( J(8t) - (1 - \ln 2) \right) \tag{6.8}
$$

$$
- \frac{1}{4} \int_0^t I^2(8x) \frac{dx}{x} + \int_0^t I(8x) \frac{dx}{x} + 2 \int_0^t \left( J'(8x) + \frac{S'(4x)}{2S(4x)} \right) \left( 1 + \frac{I(8x)}{2x} \right) dx.
$$

The small $t$-behavior of $\Phi(t)$ and $\Psi(t)$ can be determined from \eqref{2.4} and \eqref{2.19}, we have, as $t \to 0$,

$$
\Phi(t) = \frac{t^2}{3} + O \left( t^3 \right), \quad \Psi(t) = 5t - \frac{9}{2} t^2 + O \left( t^3 \right).
$$

Back to \eqref{6.2}, we have on one hand

$$
\sigma_{N,t} \sim \frac{N!}{e^{N\Phi(t) + \Psi(t)}} \quad \text{as} \quad t \to 0. \tag{6.9}
$$

On the other hand, if we let $N, \alpha \to \infty$ such that $N t^2 \to 0$ (i.e. in particular $t \to 0$), then \eqref{6.6} and the behavior of $\Phi(t)$ and $\Psi(t)$ at the origin imply, that

$$
\sigma_{N,t} \sim \frac{C_0 N!}{e^{N\Phi(t) + \Psi(t)}} \quad \text{as} \quad N, \alpha \to \infty : N t^2 \to 0. \tag{6.10}
$$

Comparing \eqref{6.9} with \eqref{6.10}, this implies

$$
C_0 = 1,
$$

and we have therefore shown

**Theorem 6.1.** *In the double scaling limit $N, \alpha \to \infty$*

$$
Z_N = N! \left( \frac{\alpha^2 - 1}{2\alpha} \right)^{N^2} \left( \frac{2}{\alpha} \right)^N e^{N\Phi(t) + \Psi(t)} \left( 1 + O \left( N^{-1} \right) \right), \tag{6.11}
$$
where $\Phi(t)$ and $\Psi(t)$ are given explicitly in (6.7), (6.8) and the error term is uniform on any finite interval $0 \leq t \leq t_0$.

The explicit evaluation of the numerical constant $C_0$ is crucial for our further strategy. In order to compute the constants $c$ and $d$, we will go back to (6.4), evaluate now the sums in the limit $t \to \infty$ and then compare the result with (1.15) and (5.3).

7. Proof of theorem 1.2

The computations in the last section lead to the following expansion for $\sigma_{N,t}$, as $N \to \infty$

$$\sigma_{N,t} = \frac{N!}{1 - \tau^2} \exp \left[ \sum_{k=1}^{N-1} \left( 2 \ln \left( \frac{b}{4} \right) + k(l + 2) + \frac{v - \frac{7}{6}}{k} \right) \right] (1 + O(N^{-1}))$$

where the error term is uniform with respect to the parameter $0 \leq \tau \leq 1 - \varepsilon < 1$. In order to derive (1.15) including the constant term, we now evaluate the sums in the last estimation in the limit $N \to \infty$ as $\alpha > 1$ and $t > t_0$ (i.e. $t \to \infty$). This time we use the Euler-Maclaurin type summation formula

$$\sum_{k=1}^{N-1} g(k\tau) = \frac{1}{\tau} \int_0^t g(x) \, dx - \frac{1}{2\tau} \int_0^\tau g(x) \, dx - \frac{1}{2\tau} \int_{t-\tau}^t g(x) \, dx + R$$

with

$$R = \frac{1}{4\tau} \sum_{k=1}^{N-1} \int_{-\tau}^{\tau} g''(k\tau + u)(x-u) \, du \, dx = O\left( \tau \int_0^\tau |g''(x)| \, dx \right)$$

which holds for a twice differentiable function $g : \mathbb{R} \to \mathbb{R}$. To derive formula (7.1), we write the Taylor formula with an integral form for the remainder

$$g(s + x) = g(s) + g'(s)x + \frac{1}{2} \int_0^x g''(s + u)(x-u) \, du,$$

then integrate from $-\tau$ to $\tau$,

$$\int_{-\tau}^\tau g(s + x) \, dx = 2g(s)\tau + \frac{1}{2} \int_{-\tau}^\tau g''(s + u)(x-u) \, du \, dx,$$

and now sum over $\{s = k\tau, k = 1, \ldots, N-1\}$,

$$\sum_{k=1}^{N-1} \int_{-\tau}^{\tau} g(k\tau + x) \, dx = 2 \sum_{k=1}^{N-1} g(k\tau)\tau + \frac{1}{2} \sum_{k=1}^{N-1} \int_{-\tau}^{\tau} g''(k\tau + u)(x-u) \, du \, dx,$$

which implies (7.1).

From (2.20) and (2.21), as $N \to \infty$,

$$\sum_{k=1}^{N-1} 2 \ln \left( \frac{b}{4} \right) = -2(N-1) \ln(1-\tau) - \ln t + c_1 + O(\tau) + O\left( t^{-1/2} \right)$$

(7.2)

where we introduced as abbreviation

$$c_1 = \int_0^1 \left( I(8x) \frac{dx}{x} + \int_1^\infty \frac{dx}{x} \right) = -3 \ln 2 + \int_0^1 I(x) \frac{dx}{x} + \int_1^\infty I(x) \frac{dx}{x} = -\ln 2.$$
and the error terms are uniform with respect to the parameters $0 \leq \tau \leq 1 - \varepsilon < 1$ and $t > t_0$. Next, combining (2.9) with (2.14),

$$v = \frac{7}{6} + O\left(\frac{\tau}{\sqrt{1 + t}}\right),$$

and hence,

$$\sum_{k=1}^{N-1} v - \frac{7}{6} = O(\tau) + O\left(\tau t^{-1/2}\right). \quad (7.3)$$

The evaluation of the remaining term involving the Lagrange multiplier will be split into several parts. First

$$\sum_{k=1}^{N-1} k(l + 2) = N(N - 1) + 2(1 - \ln 2)(N - 1)^2 + \sum_{k=1}^{N-1} \ln S(tb) + \sum_{k=1}^{N-1} 2J(2bt)$$

$$+ \sum_{k=1}^{N-1} k \left(2\ln b - \frac{b}{2}(1 - \tau) - b\right)$$

$$\equiv N(N - 1) + 2(1 - \ln 2)(N - 1)^2 + \Sigma_1 + \Sigma_2 + \Sigma_3. \quad (7.4)$$

For $\Sigma_1$, use the asymptotic formula

$$\ln S(x) = x - \ln(2x) + O\left(e^{-2x}\right), \quad x \to +\infty$$

and derive

$$\Sigma_1 = \frac{2\tau}{1 - \tau}(N - 1)^2 - N\ln\left(\frac{8t}{1 - \tau}\right) + N\sqrt{N} \zeta(3/2) + \ln t$$

$$+ \alpha c_2 + c_3 + O(\tau) + O\left(t^{-1/2}\right) + O\left(\alpha e^{-8t}\right),$$

valid in the limit $N \to \infty, \alpha > 1$ with $t \to \infty$. Here we have

$$c_2 = \int_0^\infty (\ln S(4x) - 4x + \ln(8x)) \, dx = \frac{1}{8} \int_0^\infty \ln(1 - e^{-x}) \, dx = -\frac{\pi^2}{48}$$

$$c_3 = \frac{3}{2} \ln 2 + \int_0^\infty 4x \left(\frac{S'(4x)}{S(4x)} - 1 + \frac{1}{4x}\right) \left(1 + \frac{I(8x)}{2x}\right) \, dx + 2 \int_0^\infty \left(I(8x) + 1 - \frac{\zeta(3/2)}{4\sqrt{2\pi x}}\right) \, dx$$

$$- \frac{1}{2} \int_0^1 I(8x) \frac{dx}{x} - \frac{1}{2} \int_1^\infty (I(8x) + 1) \frac{dx}{x} = 2\ln 2 + \frac{\pi^2}{48} + \frac{1}{2} \int_0^\infty \frac{I(x)}{e^x - 1} \, dx,$$

and we simplified the expressions for $c_i$, by recalling the definitions of $S(x)$ and $I(x)$ as well as the integrals

$$\int_0^\infty \ln(1 - e^{-x}) \, dx = -\frac{\pi^2}{6}, \quad \int_0^\infty \frac{x \, dx}{e^x - 1} = \frac{\pi^2}{6}.$$

Next we go back to Proposition 2.4 and derive

$$\Sigma_2 = \alpha c_4 + c_5 + O(\tau) + O\left(\alpha t^{-1/2}\right)$$
where
\[ c_4 = 2 \int_0^\infty J(8x) \, dx = \frac{1}{4} \int_0^\infty J(x) \, dx = \frac{\pi^2}{48} \]

\[ c_5 = -(1 - \ln 2) + 16 \int_0^\infty xJ'(8x) \left( 1 + \frac{I(8x)}{2x} \right) \, dx = -(1 - \ln 2) - \frac{\pi^2}{48} + \int_0^\infty J'(x)I(x) \, dx, \]

in the limit \( N \to \infty, \alpha > 1 \), with error terms which are uniform with respect to the parameters \( 0 \leq \tau \leq 1 - \varepsilon < 1 \) and \( t > t_0 \). Here we have used the definite integrals
\[ \int_0^1 \left( \sqrt{\frac{x}{1-x}} - \arctan \sqrt{\frac{x}{1-x}} \right) \frac{dx}{x^2} = \frac{\pi}{2}, \quad \int_0^1 \left( \sqrt{\frac{x}{1-x}} - \sqrt{x} \right) \frac{dx}{x^2} = 2 \]

in order to simplify the expressions for \( c_i \). Finally with (2.9) and Proposition 2.1,
\[ \Sigma_3 = N(N-1)\ln \left( \frac{4}{1-\tau} \right) - N(N-1) - \frac{2}{1-\tau}(N-1)^2 - \zeta \left( \frac{3}{2} \right) \alpha \sqrt{\frac{N}{2\pi(\alpha-1)}} \]
\[ -\frac{1}{4} \ln t + \alpha c_6 + c_7 + O(\tau) + O \left( \alpha t^{-1/2} \right) \]

where
\[ c_6 = -2 \int_0^\infty \left( I(8x) + 1 - \frac{\zeta(3/2)}{4\sqrt{2\pi x}} \right) \, dx = 0 \]
\[ c_7 = 1 - \frac{1}{4} \int_0^\infty \frac{I^2(8x)}{4x} \, dx - 2 \int_0^\infty \left( I'(8x) + \frac{\zeta(3/2)}{4\sqrt{\pi(8x)^{3/2}}} \right) 8x \left( 1 + \frac{I(8x)}{2x} \right) \, dx \]
\[ + \int_0^\infty \left( 1 - I^2(8x) \right) \frac{dx}{4x} - 2 \int_0^\infty \left( I(8x) + 1 - \frac{\zeta(3/2)}{4\sqrt{2\pi x}} \right) \, dx \]
\[ -\frac{\zeta(3/2)}{2\sqrt{2\pi}} \int_0^\infty \left( 4I'(8x) - \frac{I(8x)}{2x} \right) \frac{dx}{\sqrt{x}} = \frac{1}{2} - \frac{3}{4} \ln 2 - \frac{1}{4} \int_0^1 \frac{I^2(x)}{x} \, dx + \frac{1}{4} \int_1^\infty \left( 1 - I^2(x) \right) \frac{dx}{x}. \]

Now back to (7.4), as \( N \to \infty, \)
\[ \sum_{k=1}^{N-1} k(l+2) = -N^2 \ln(1-\tau) + 2N \ln(1-\tau) - N \ln(2t) + N - \sqrt{N} \zeta \left( \frac{3}{2} \right) \sqrt{\frac{\alpha-1}{2\pi}} \]
\[ + \frac{3}{4} \ln t + \alpha(c_2 + c_4 + c_6) + c_3 + c_5 + c_7 - 2 \ln 2 \]
\[ + O(\tau) + O \left( \alpha t^{-1/2} \right) \tag{7.5} \]

which is uniform with respect to the parameters \( 0 \leq \tau \leq 1 - \varepsilon < 1 \) and \( t > t_0 \). In order to obtain the desired expansion for \( \sigma_{N,t} \) we combine estimations (7.2), (7.3) and (7.5), as \( N \to \infty \)
\[ \sigma_{N,t} = \left( \frac{\alpha}{\alpha-1} \right)^N \frac{\alpha}{2} \bar{C}_{N,t} G^{\sqrt{N}} N^{1/4} \left( 1 + O \left( N^{-1} \right) \right), \quad G = \exp \left[ -\zeta \left( \frac{3}{2} \right) \sqrt{\frac{\alpha-1}{2\pi}} \right] \]
with
\[ \hat{C}_{N,t} = (\alpha - 1)^{1/4} \exp \left[ d_0 \alpha + c_0 + O(\tau) + O\left(\alpha t^{-1/2}\right) \right] \]
where all error terms are uniform with respect to the parameters \(0 \leq \tau \leq 1 - \varepsilon < 1\) and \(t > t_0\).

The factors \(d_0\) and \(c_0\) are given as
\[ d_0 = c_2 + c_4 + c_6 = 0 \quad (7.6) \]
and
\[ c_0 = -\frac{1}{2} - \frac{1}{4} \ln 2 + \frac{1}{2} \ln \pi + \frac{1}{2} \int_0^\infty I(x) \frac{dx}{e^x - 1} + \frac{1}{2} \int_0^\infty J'(x) I(x) dx - \frac{1}{4} \int_0^1 I^2(x) \frac{dx}{x} + \frac{1}{4} \int_1^\infty (1 - I^2(x)) \frac{dx}{x} \quad (7.7) \]

We have therefore shown

**Proposition 7.1.** In the limit \(N \to \infty\),
\[ Z_N = \hat{C}_{N,t} F^N G^N N^{1/4} \left(1 + O\left(N^{-1}\right)\right), \quad F = \frac{\alpha + 1}{2}, \quad G = \exp \left[-\zeta \left(\frac{3}{2}\right) \sqrt{\frac{\alpha - 1}{2\pi}}\right] \quad (7.8) \]
with
\[ \hat{C}_{N,t} = (\alpha - 1)^{1/4} \exp \left[c_0 + O(\tau) + O\left(\alpha t^{-1/2}\right)\right], \]
where \(c_0\) is given explicitly in (7.7) and the error terms are uniform with respect to the parameters \(0 \leq \tau \leq 1 - \varepsilon < 1\) and \(t > t_0\).

The last proposition allows us to prove Theorem 1.2. To this end let us choose \(\alpha\) from a compact subset of the set
\[ \{ \alpha \in \mathbb{R} : \alpha > 1 \}. \]

Then, as \(N \to \infty\),
\[ Z_N = (\alpha - 1)^{1/4} e^{c_0 + O(\tau)} F^N G^N N^{1/4} \left(1 + O\left(N^{-1/2}\right)\right) \]
where the error term is uniform on any compact subset of the set (1.16). Comparing the last line with (5.3), we obtain
\[ d = 0, \quad c = c_0. \]

In order to derive the stated expression for \(c\) in Theorem 1.2, we will simplify the integrals appearing in (7.7) as follows. For the last two integrals in (7.7), we replace one of the factors in the products \(I^2(x)\) with its definition (1.26). Evaluating the integrals and recalling our computations for \(c_1\), we obtain

\[ -\frac{1}{4} \int_0^1 I^2(x) \frac{dx}{x} + \frac{1}{4} \int_1^\infty (1 - I^2(x)) \frac{dx}{x} = \frac{1}{2} \ln 2 - \frac{1}{4\pi^2} \int_0^1 \frac{u}{1 - u} \int_0^1 \frac{v}{1 - v} \]
\[ \times \left[ \int_0^\infty \left( \frac{1}{e^{xv} - 1} - \frac{1}{xv} \right) \frac{dx}{e^{xu} - 1} \right] du dv. \]

Next, we use geometric progression for \(\frac{1}{e^{xv} - 1}\) and integrate term by term
\[ \int_0^\infty \left( \frac{1}{e^{xv} - 1} - \frac{1}{xv} \right) \frac{dx}{e^{xu} - 1} = \sum_{n=1}^\infty \left[ \frac{1}{nu} + \sum_{m=1}^\infty \frac{1}{(nu + mv)^2} \right], \quad 0 < u, v < 1. \]
With the help of the integrals
\[
\int_0^1 \frac{u}{\sqrt{1 - u(1 + au)^2}} \, du = \frac{\pi}{2(1 + a)^{3/2}}, \quad \int_0^1 \frac{du}{\sqrt{1 - u(a + u)^3}} = \frac{2}{(1 + a)\sqrt{a}}, \quad a \geq 0
\]
this implies
\[
-\frac{1}{4} \int_0^1 I^2(x) \, dx + \frac{1}{4} \int_1^\infty (1 - I^2(x)) \frac{dx}{x} = \frac{1}{2} \ln 2 - \frac{1}{4\pi} \sum_{n=1}^\infty \left[ -\frac{\pi}{n} + \sum_{m=1}^\infty \frac{1}{(m + n)\sqrt{mn}} \right]. \tag{7.9}
\]
For the second integral in (7.7) we use the identities
\[
J'(x) = I'(x) - \frac{1}{\pi} \int_0^1 \arctan \left( \frac{x}{1 - xu} \right) \, du, \quad \frac{\partial}{\partial x} \left( \frac{x}{e^{xu} - 1} \right) = \frac{\partial}{\partial u} \left( \frac{u}{e^{xu} - 1} \right)
\]
and integrate by parts
\[
\int_0^\infty J'(x)I(x) \, dx = \frac{1}{2} - \frac{1}{2} \int_0^\infty \frac{I(x)}{e^x - 1} \, dx + \frac{1}{2\pi} \int_0^1 \sqrt{\frac{u}{1 - u}} \frac{I(x)}{e^{xu} - 1} \, du dx.
\]
Since
\[
I(x) = \frac{x}{\pi} \int_0^1 \sqrt{\frac{v}{1 - v}} \left( \frac{1}{e^{xv} - 1} - \frac{1}{xv} \right) \, dv,
\]
we obtain
\[
\frac{1}{2\pi} \int_0^\infty \int_0^1 \sqrt{\frac{u}{1 - u}} \frac{I(x)}{e^{xu} - 1} \, du \, dx = \frac{1}{2\pi^2} \int_0^1 \sqrt{\frac{u}{1 - u}} \left[ \int_0^\infty \frac{1}{e^{xu} - 1} - \frac{1}{xu} \right] \, dx \, du,
\]
i.e. the triple integral we just evaluated in the computation of (7.9). We summarize
\[
\int_0^\infty J'(x)I(x) \, dx = \frac{1}{2} - \frac{1}{2} \int_0^\infty \frac{I(x)}{e^x - 1} \, dx + \frac{1}{2\pi} \sum_{n=1}^\infty \left[ -\frac{\pi}{n} + \sum_{m=1}^\infty \frac{1}{(m + n)\sqrt{mn}} \right] \tag{7.10}
\]
and back to (7.7),
\[
c = \frac{1}{4} \ln 2 + \frac{1}{2} \ln \pi + \frac{1}{4\pi} \sum_{n=1}^\infty \left[ -\frac{\pi}{n} + \sum_{m=1}^\infty \frac{1}{(m + n)\sqrt{mn}} \right],
\]
thus proving Theorem 1.2.
