Neutrino Mass and Dark Matter from Gauged B–L Breaking *

Toshinori Matsui†
Department of Physics, University of Toyama, Toyama 930-8555, Japan

We discuss a new radiative seesaw model with the gauged B–L symmetry which is spontaneously broken. We improve the previous model by using the anomaly-free condition without introducing too many fermions. In our model, dark matter, tiny neutrino masses and neutrino oscillation data can be explained simultaneously, assuming the B–L symmetry breaking at the TeV scale.

I. INTRODUCTION

The neutrino oscillation data \[2\] have shown us neutrinos have tiny masses. If ν_R are introduced to the standard model of particle physics (SM), there are two possible mass terms for neutrinos (See e.g., Ref. \[5\]), the Dirac type (ν_R)_i (ν_R)_i and the Majorana type (ν_R)_i (ν_R)_i. In radiative seesaw models (See e.g., Refs. \[6\]–\[12\]), an ad hoc unbroken Z_2 symmetry forbids generating neutrino masses at the tree level and explains the dark matter (DM) stability. A model in Ref. \[12\] was constructed such that the breaking of the U(1)_{B–L} gauge symmetry gives a residual symmetry for the DM stability and the Majorana neutrino mass of ν_R. However, the anomaly cancelation for the U(1)_{B–L} gauge symmetry requires to introduce more additional fermions except for particles for the radiative neutrino mass.

In this talk, we propose a new model which is an improved version of the model in Ref. \[12\] from the view point of the anomaly cancellation. With appropriate U(1)_{B–L} charge assignments, there exists an unbroken global U(1) symmetry even after the breakdown of the U(1)_{B–L} symmetry. The global U(1) symmetry stabilizes the DM, so that we hereafter call it U(1)_{DM}. In our work, the DM candidate is a new scalar boson. Furthermore, the Dirac mass term of neutrinos is radiatively generated at the one-loop level due to the quantum effect of the new particles. Tiny neutrino masses are explained by the two-loop diagrams with a Type-I-Seesaw-like mechanism. We find that the model can satisfy current data from the neutrino oscillation, the lepton flavor violation (LFV), the relic abundance and the direct search for the DM, and the LHC experiment.

II. MODEL

We introduce new particles which listed in Table I. We determine assignment of U(1)_{B–L} charges from conditions for cancellation of the [U(1)_{B–L}] \times \text{[gravity]}^2 and [U(1)_{B–L}]^3 anomalies:

\[
3 - \frac{1}{3} N_{ν_R} - \frac{2}{3} N_ψ = 0, \quad 3 - \frac{1}{27} N_{ν_R} + \left( -2 x^2 - \frac{4}{3} x - \frac{8}{27} \right) N_ψ = 0, \tag{1}
\]

where N_ψ is the number of ψ_R (the same as the number of ψ_{Li}), and N_{ν_R} is the number of ν_{Ri}.

There are four solutions as presented in Table II. Except for Case III, the U(1)_{B–L} charges of some new particles are irrational numbers while the U(1)_{B–L} symmetry is spontaneously broken by the vacuum expectation value (VEV) of σ^0 whose U(1)_{B–L} charge is a rational number. Therefore, the irrational charges are conserved, and the lightest particle with an irrational U(1)_{B–L} charge becomes stable so that the particle can be regarded as a DM candidate. In this talk, we take Case IV as an example.

In addition to the SM one, the new Yukawa interactions are given by

\[
\mathcal{L}_Y = - (y_R)_i (ν_R)_i (ψ_R)_i (σ^0)_i + (y_ψ)_i (ψ_L)_i (ν_R)_i (σ^0)_i + h_{ij} (ψ_L)_i (ν_R)_j s^0 - f_ℓ (L_L)_ℓ (ψ_R)_ℓ \bar{η} + \text{h.c.}, \tag{2}
\]

where \(\bar{η} \equiv i σ_2 \eta^*\). The scalar potential in our model is the same as that in the previous model \[12\]:

\[
V = - μ_σ^2 Φ^+ Φ + μ_σ^2 |σ^0|^2 + μ_1^2 σ^0 η^* η - μ_σ^2 |σ^0|^2 + μ_1^2 (σ^0 η^* Φ + \text{h.c.}) + λ_σ (Φ^+ Φ)^2 + λ_σ |σ^0|^4 + λ_η (η^* η)^2 + λ_σ |σ^0|^4 + λ_σ |σ^0|^2 |σ^0|^2 + λ_σ |σ^0|^2 η^* η + λ_σ |σ^0|^2 Φ^+ Φ + λ_σ |σ^0|^2 η^* η + λ_σ |σ^0|^2 Φ^+ Φ + \lambda_φ (η^* η) (Φ^+ Φ) + \lambda_φ (η^* η) (Φ^+ Φ). \tag{3}
\]

* This talk is based on Ref. \[1\].
†Electronic address: matsui@jodo.sci.u-toyama.ac.jp
Tiny neutrino masses are generated by two-loop diagrams in Fig. 1 \[12\]. The mass matrix run from 1 to 0
\[\eta \phi \to \eta \psi \to \nu_{Li} \to \nu_{Lj}, \eta \phi \to \eta \psi \to \nu_{Lk} \to \nu_{Li}, \eta \phi \to \eta \psi \to \nu_{Lj} \to \nu_{Lk}\].

Neutral scalar fields are given by \(\phi^0 = \sqrt[\lambda]{(\phi^0 + i \sigma^0)}, \sigma^0 = \sqrt[\lambda]{(\sigma^0 + i \eta^0)}, \eta^0 = \sqrt[\lambda]{(\eta^0 + i \eta^0)}, s^0 = \sqrt[\lambda]{(s^0 + i s^0)}\).

Two scalar fields \(\phi^0\) and \(\sigma^0\) obtain VEVs \(v_\phi = \sqrt{2} \langle \phi^0 \rangle = 246 \text{ GeV} \) and \(v_\sigma = \sqrt{2} \langle \sigma^0 \rangle\). The VEVs \(v_\phi\) provides a mass of the U(1)B-L gauge boson \(Z'\) as \(m_{Z'} = (2/3) g_{B-L} v_\sigma\), where \(g_{B-L}\) is the U(1)B-L gauge coupling constant. After the gauge symmetry breaking with \(v_\phi\) and \(v_\sigma\), we can confirm in Eqs. (2) and (3) that there is a residual global U(1)DM symmetry, for which irrational U(1)B-L-charged particles \((\eta, s^0, \psi_L, \psi_R)\) have the same U(1)DM-charge while the other particles are neutral.

Two CP-even scalar particles \(h^0\) and \(H^0\) are obtained by \(\phi^0-s^0\) mixing as \(sin 2\theta_0 = \frac{2\lambda v_\phi v_\sigma}{m_{h^0} - m_{H^0}}\). Two neutral complex scalars \(\eta^0\) and \(s^0\) are obtained by \(\eta^0-s^0\) mixing as \(sin 2\theta_0 = \frac{\sqrt{2} v_\phi v_\sigma}{m_{\eta^0} - m_{s^0}}\).

Scalar masses are given by
\[m_{h^0}^2 = \lambda_\phi v_\phi^2 + \lambda_s v_s^2 + \sqrt{(\lambda_\phi v_\phi^2 - \lambda_s v_s^2)^2 + (2 \lambda_{\phi s} v_\phi v_s)^2}, m_{s^0}^2 = \frac{1}{2} m_\sigma^2 + \sqrt{(m_\eta^2 - m_s^2)^2 + 2 \mu_\phi^2 v_\phi^2},\]

where \(m_\eta^2 = \mu_\eta^2 + (\lambda_{\phi \eta} + \lambda_{\eta \phi}) v_\phi^2 v_\sigma^2/2 + \lambda_{\phi \sigma} v_\phi v_\sigma^2/2, m_s^2 = \mu_s^2 + \lambda_{\phi s} v_\phi^2 v_\sigma^2/2 + \lambda_{\sigma s} v_\sigma^2/2\). The mass of the charged scalar \(\eta^+\) is \(m_{\eta^+}^2 = m_\eta^2 - \lambda_{\eta \phi} v_\phi^2 v_\sigma^2/2\). Nambu-Goldstone bosons \(z_\eta\) and \(z_s\) are absorbed by \(Z\) and \(Z'\) bosons, respectively.

### III. PHENOMENOLOGY

#### A. Neutrino masses

Tiny neutrino masses are generated by two-loop diagrams in Fig. 1 [12]. The mass matrix \(m_\nu\) is expressed in the flavor basis as
\[(m_\nu)_{\ell\ell'} = \sum_{i,j,a} f_{\ell i} h_{ia} (m_{Ri})_{a} (h^T)_{aj} (f^T)_{j\ell'} \left[ (I_1)_{ij} + (I_2)_{ij} \right] / (16\pi^2)^2,\]

where explicit formulas of \((I_1)_{ij}\) and \((I_2)_{ij}\) are shown in Ref. [1]. The neutrino mass matrix \((m_\nu)_{\ell\ell'}\) is diagonalized by a unitary matrix \(U_{\text{MNS}}\), the so-called Maki-Nakagawa-Sakata (MNS) matrix [13], as
\[U_{\text{MNS}}^T m_\nu U_{\text{MNS}} = \text{diag}(m_1 e^{i\alpha_1}, m_2 e^{i\alpha_2}, m_3 e^{i\alpha_3})\]. We take \(m_i\) \((i = 1-3)\) to be real and positive values. Two differences of three phases \(\alpha_i\) are physical Majorana phases. In our analysis, the following values [2, 3] obtained by neutrino oscillation measurements are used in order to search for a benchmark point of model parameters:

\[\sin^2 2\theta_{23} = 1, \quad \sin^2 2\theta_{13} = 0.09, \quad \tan^2 \theta_{12} = 0.427, \quad \delta = 0, \quad \{\alpha_1, \alpha_2, \alpha_3\} = \{0, 0, 0\},\]

\[m_1 = 10^{-4} \text{ eV}, \quad \Delta m^2_{21} = 7.46 \times 10^{-5} \text{ eV}^2, \quad \Delta m^2_{32} = 2.51 \times 10^{-3} \text{ eV}^2, \quad \text{where } \Delta m^2_{ij} \equiv m_i^2 - m_j^2.\]

By using an ansatz [1] for the structure of Yukawa matrix \(f_{\ell i}\), we found a benchmark point as
\[f \approx \begin{pmatrix} 1.79 & -2.49 & -1.97 & 2.56 \\ -1.82 & 1.10 & 1.30 & -0.818 \\ 1.40 & -0.598 & -0.905 & 0.222 \end{pmatrix} \times 10^{-2}, \quad h = \begin{pmatrix} 0.7 & 0.8 & 0 & 1 \end{pmatrix}^T, \quad \{g_{B-L}, m_{Z'}\} = \{0.1, 4 \text{ TeV}\},\]

\[\{m_{\nu \theta}, m_{\nu \phi}, \cos \theta_0\} = \{125 \text{ GeV}, 1 \text{ TeV}, 1\}, \quad \{m_{\nu_1}, m_{\nu_2}, \cos \theta_0\} = \{60 \text{ GeV}, 450 \text{ GeV}, 0.05\},\]

\[m_{\eta^2} = 420 \text{ GeV}, \quad \{m_{\nu_1}, m_{\nu_2}, m_{\psi_1}, m_{\psi_2}, m_{\psi_3}, m_{\psi_4}\} = \{650 \text{ GeV}, 750 \text{ GeV}, 850 \text{ GeV}, 950 \text{ GeV}\}.\]

The values of \(m_{\nu_1}, m_{\nu_2}, \cos \theta_0\) correspond to \(\lambda_\phi \simeq 0.13, \lambda_s \simeq 2.8 \times 10^{-4}\) and \(\lambda_{\phi \sigma} = 0\). The values of \(m_{\eta_1}, m_{\eta_2}, \cos \theta_0\) and \(m_{\eta^2}\) can be produced by \(m_\sigma \simeq 60 \text{ GeV}, m_\eta \simeq 450 \text{ GeV}, \mu_3 \simeq 57 \text{ GeV}\) and \(\lambda_{\eta \phi} \simeq 0.86\).

### Table I: Particle contents in this model. Indices \(i\) and \(a\) run from 1 to \(N_\nu\) and from 1 to \(N_{\nu_R}\), respectively.

| \(\sigma^0\) | \((\nu_R)_a\) | \((\psi_L)_i\) | \((\psi_R)_j\) | \(\eta\) | \(s^0\) |
|---|---|---|---|---|---|
| SU(2)_I | 1 | 1 | 1 | 1 | 1 |
| U(1)_Y | 0 | 0 | 0 | 1/2 | 0 |
| U(1)_{B-L} | 2/3 | -1/3 | \(x + 2/3\) | \(x + 1\) | \(x + 1\) |
| Spin | 0 | 1/2 | 1/2 | 1/2 | 0 |

### Table II: Sets of \(N_\nu, N_{\nu_R}\) and \(x\), for which the U(1)_{B-L} gauge symmetry is free from anomaly.

| Case I | Case II | Case III | Case IV |
|---|---|---|---|
| \(N_\nu\) | \(N_{\nu_R}\) | \(x\) | \(\eta\) |
| 1 | 2 | 3 | 4 |
| 7 | 5 | 3 | 1 |

\[\frac{\eta_{\phi}}{\eta_{\psi}} \frac{\phi}{\psi}\]
We consider the condition of the LFV decays of charged leptons. The charged scalar $\eta^\pm$ contributes to the branching ratio (BR) of $\mu \to e\gamma$ whose formula have been calculated [14]. At the benchmark point, we have BR($\mu \to e\gamma$) = $6.1 \times 10^{-14}$ which satisfies the current constraint BR($\mu \to e\gamma$) < $5.7 \times 10^{-13}$ (90% C.L.) [15].

C. Dark matter

In our model, the scalar $H_1^0$ turns out to be the DM candidate due to the following reason. If the DM is the fermion $\psi_1$, it annihilates into a pair of SM particles via the s-channel process mediated by $h^0$ and $H^0$. Even for a maximal mixing $\cos \theta_0 = 1/\sqrt{2}$ [16], the observed abundance of the DM [17] requires $v_\sigma \lesssim 10$ TeV. The current constraint from direct searches of the DM [18] requires larger $v_\sigma$ in order to suppress the $Z'$ contribution.

The scalar DM $H_1^0$ at the benchmark point is dominantly made from $s^0$ which is a gauge-singlet field under the SM gauge group, because of the tiny mixing $\cos \theta_0' = 0.05$. The annihilation of $H_1^0$ into a pair of the SM particles is dominantly caused by the s-channel scalar mediation via $h^0$ because $H^0$ is assumed to be heavy. The coupling constant $\lambda_{H_0^0 H_1^0 s^0}$ for the $\lambda_{H_0^0 H_1^0 H_1^0} v_\sigma H_1^0 H_1^0$ interaction controls the annihilation cross section, the invisible decay $h^0 \to H_1^0 H_1^0$ in the case of kinematically accessible, and the $h^0$ contribution to the spin-independent scattering cross section $\sigma_{SI}$ on a nucleon. In Ref. [20], for example, we see that $H_1^0$ with $m_{H_1^0} = 60$ GeV and $\lambda_{H_0^0 H_1^0 s^0} \sim 10^{-3}$ can satisfy constraints from the relic abundance of the DM and the invisible decay of $h^0$. We see also that the $h^0$ contribution to $\sigma_{SI}$ is small enough to satisfy the current constraint $\sigma_{SI} < 9.2 \times 10^{-46}$ cm$^2$ for $m_{H^0} = 60$ GeV [18]. Although the scattering of $H_1^0$ on a nucleon is mediated also by the $Z'$ boson in this model, the contribution can be suppressed by taking a large $v_\sigma$. The benchmark point corresponds to $v_\sigma = 60$ TeV and gives about $6.6 \times 10^{-47}$ cm$^2$ for the scattering cross section via $Z'$, which is smaller than the current constraint [18] by an order of magnitude. Thus, the constraint from the direct search of the DM is also satisfied at the benchmark point.

D. $Z'$ and $\nu_R$ search

The LEP-II bound $m_{Z'}/g_{B-L} \gtrsim 7$ TeV [21] is satisfied at the benchmark point because of $m_{Z'}/g_{B-L} = 40$ TeV which we take for a sufficient suppression of $\sigma_{SI}$ for the direct search of the DM. The production cross section of $Z'$ with $g_{B-L} = 0.1$ and $m_{Z'} = 4$ TeV is about 0.3 fb at the LHC with $\sqrt{s} = 14$ TeV [22]. Notice that the current bound $m_{Z'} \gtrsim 3$ TeV at the LHC [23] is for the case where the gauge coupling for $Z'$ is the same as the one for $Z$, namely $g_{B-L} \simeq 0.7$. Decay branching ratios of $Z'$ are shown at the benchmark point in Table [11].

Decays of $\psi_1$ are dominated by $\psi_1 \to \nu_R H_1^0$ with the Yukawa coupling constants $h_1$ because $h_{1R}$ for $\psi_1 \to \ell^\pm \eta^\mp$ are small in order to satisfy the $\mu \to e\gamma$ constraint. The $H_1^0 (\sim \eta^0)$ decays into $h^0 H_1^0$ via the trilinear coupling constant $\mu_3$. The main decay mode of $\eta^\pm$ is $\eta^\pm \to W^\pm H_1^0$ through the mixing $\theta_0'$ between $\eta^0$ and $s^0$.

The $\nu_R\rightarrow H^0$ decay is forbidden because it is heavier than $\nu_R$ at the benchmark point. Since the $B-L$ charge of $\nu_R$ is rather small, $\nu_R$ is not produced directly from $Z'$. However, $\nu_R$ can be produced through the decays of $\psi_1$. As a result, about 18% of $Z'$ produces $\nu_R$. For $\nu_R \rightarrow W\ell$ (56%) followed by the hadronic decay of $W$ (68%), the $\nu_R$ would be reconstructed. In this model, an invariant mass of a pair of the reconstructed $\nu_R$ is not at $m_{Z'}$, in contrast with a naive model where only three $\nu_R$ with $B-L = -1$ are introduced to the SM. This feature of $\nu_R$ also enables us to distinguish this model from the previous model in Ref. [12] where $\nu_R$ with $B-L = 1$ can be directly produced by the $Z'$ decay.
In our model, unbroken global U(1)DM guarantees that the lightest U(1)DM-charged particle is stable such that it can be regarded as a DM candidate. The spontaneous breaking of the U(1)B−L symmetry generates the Majorana mass term of ν_R and masses of new fermions ψ. In addition, the Dirac mass term of neutrinos is generated at the one-loop level where the DM candidate involved in the loop. Tiny neutrino masses are not take a peak at Z̄, such that it can be regarded as a DM candidate. The spontaneous breaking of the U(1)_B−L symmetry generates the Majorana mass term of ν_R and masses of new fermions ψ. In addition, the Dirac mass term of neutrinos is generated at the one-loop level where the DM candidate involved in the loop. Tiny neutrino masses are obtained at the two-loop level.

The case of the fermion DM is excluded, and the lightest U(1)DM-charged scalar H_0 should be the DM in this model. We have found a benchmark point of model parameters which satisfies current constraints from neutrino oscillation data, lepton flavor violation searches, the relic abundance of the DM, direct searches for the DM, and the LHC experiments. In such radiative seesaw models, ν_R would be produced at the LHC. In our model, ν_R cannot be directly produced by the Z' decay, but can be produced by the cascade decay Z' → ψ_i̅ → ν_R H'_R H'_R. By the unusual B−L charge of ν_R, the invariant mass distribution of ν_R H'_R does not take a peak at m_{Z'}, which could be a characteristic signal.

IV. CONCLUSIONS

We have improved the model in Ref. [12] by considering anomaly cancellation of the U(1)_B−L gauge symmetry. The case of the fermion DM is excluded, and the lightest U(1)DM-charged scalar H_0 should be the DM in this model. We have found a benchmark point of model parameters which satisfies current constraints from neutrino oscillation data, lepton flavor violation searches, the relic abundance of the DM, direct searches for the DM, and the LHC experiments. In such radiative seesaw models, ν_R would be produced at the LHC. In our model, ν_R cannot be directly produced by the Z' decay, but can be produced by the cascade decay Z' → ψ_i̅ → ν_R H'_R H'_R. By the unusual B−L charge of ν_R, the invariant mass distribution of ν_R H'_R does not take a peak at m_{Z’}, which could be a characteristic signal.
