Composite Bi-2212/Ag Superconductors Grown by Laser Travelling Floating Zone at Low Rates

J. C. Diez · A. Sotelo · S. Rasekh · H. Amaveda · M. A. Torres · P. Bosque · C. Chocarro · M. A. Madre

Abstract Well-textured Bi$_2$O$_2$Sr$_2$Ca$_0.98$Cu$_{1.99}$O_{x}/2.9 wt % Ag composite samples have been grown by the laser floating zone at very low rates (1, 3, and 5 mm/h). The as-grown samples present superconducting behavior, as a result of being composed by long and well-textured Bi-2212 grains as major phase. After annealing, the samples do not dramatically increase their $J_C$. This effect has been associated with the presence of long cracks along the $ab$ planes of the superconducting grains. Even after annealing, the cracks have not been totally removed and, as a consequence, the critical current of the samples after the thermal treatment has only been improved in around 50 %, compared with the as-grown samples.

Keywords Bi-2212 · Ag · Directional growth · Critical current · Composite

1 Introduction

The development of commercial applications based on high-temperature superconductors requires the use of texturing techniques in order to obtain bulk materials with high critical current density ($J_C$) values [1]. These techniques must be reliable enough in order to assure the high $J_C$ in long lengths [2]. Although (Bi,Pb)$_2$Sr$_2$Ca$_2$Cu$_3$O$_{10+\delta}$ (Bi-2223) superconductors have a high critical temperature, $T_C$, $\sim$110 K, Bi$_2$Sr$_2$Ca$_2$Cu$_2$O$_{8+\delta}$ (Bi-2212) superconductors, with lower $T_C$, $\sim$ 90–95 K, require less complex reaction and texturing processes. Therefore Bi-2212 superconductors have demonstrated that they are suitable for many applications when properly processed, as for example by the laser floating zone (LFZ), where well-textured bulk materials are obtained [3, 4]. Recently, this technique has also been successfully used with other plate-like grain ceramic materials [5, 6].

The superconducting materials textured by the LFZ technique have very well aligned crystals, with their $c$-axis perpendicular to the current flow direction and strong grain boundaries. Bulk Bi-2212 LFZ textured materials show $J_C$ values higher than 5,000 A/cm$^2$ for $\sim$ 1-mm diameter rods [6]. This method can be improved by an electrical current crossing the melt, called electrical assisted laser floating zone (EALFZ), which is able to obtain Bi-2212 samples with improved texture [7] when compared with the classical LFZ technique. In any case, the interesting transport properties obtained in these bulk Bi-2212 textured materials allow developing practical applications, as current leads [8] or fault current limiters [9]. One of the main advantages of this method is that the materials can be rapidly grown due to the large thermal gradient at the solid-liquid interface [10, 11]. The second additional advantage is the absence of crucible, avoiding external contamination of textured samples during the processing. However, the poor mechanical characteristics of this kind of materials [12, 13] due to their ceramic nature impose some limitations for practical applications. Some attempts to improve their mechanical behavior have...
been performed by means of Ag addition on BSCCO compounds \cite{9, 14} and other plate-like grain ceramics \cite{15}.

The aim of this work is to study well-textured Bi-2212/Ag composites, with Ag content fixed in ∼3 wt%, when the texturing process is performed by means of the LFZ technique at very low rates (≤5 mm/h), in order to stabilize the solidification front. The changes on the microstructure are related with the superconducting properties of the samples.

2 Experimental

Green cylindrical ceramic precursors, ∼120 mm long and ∼3 mm diameter, have been prepared from commercial Bi$_{2.02}$Sr$_{2.02}$Ca$_{0.98}$Cu$_{1.99}$O$_{x}$/2.9 wt %Ag composite powder precursors (Nexans SuperConductors GmbH) by cold isostatic pressing with an applied pressure of 200 MPa during 1 min. The obtained green cylinders were subsequently used as feed in a directional solidification process performed in an LFZ installation described elsewhere \cite{16}. These bars have been processed using a continuous power Nd:YAG laser (λ = 1.064 nm), under air, at growth rates of 1, 3, and 5 mm/h. In the process, the seed has been rotated clockwise at 3 rpm in order to maintain the cylindrical geometry while the feed has been rotated anticlockwise at 15 rpm to homogenize the molten zone. Finally, after the growth process, the textured bars, ∼150 mm length and ∼2 mm diameter, have shown to be very homogeneous dimensionally. These rods were then cut into several pieces with the adequate dimensions (∼35 mm long) for their electrical characterization. Some of these as-grown samples were characterized, while others were subjected to an annealing process under air consisting in two steps: 60 h at 860°C to produce the maximum amount of Bi-2212 phase, followed by 12 h at 800°C to adjust the oxygen content in the superconducting phase and, finally, quenched in air to room temperature. Moreover, four silver contacts were painted on these samples, two of about 5 mm at both ends of the bars for the current injection and two small ones in the center of the bar, with ∼1 cm between them, for the voltage measurements.

Morphological and microstructural characterization, before and after annealing, was made on polished longitudinal cross-sections of the samples in a field emission scanning electron microscope (FESEM, Zeiss Merlin) equipped with an energy dispersive spectroscopy (EDX) system. Powder X-ray diffraction (XRD) patterns have also been recorded, with 2θ ranging between 5° and 40°, in order to identify the different phases (Rigaku D/max-B X-ray powder diffractometer working with CuKα radiation).

Electrical measurements were performed by the conventional four-point probe configuration in both, as-grown and annealed samples. Resistivity as a function of temperature, from 77 to 300 K, was measured using a DC current of 1 mA. Critical current density ($J_C$) values were determined at 77 K, from the I–V curves, using the 1 µV/cm standard criterion.

3 Results and Discussion

Figure 1 shows representative SEM images of as-grown samples grown at different rates. Although the heat treatment has not been performed in these samples, the major phase (grey contrast matrix) corresponds to the superconducting Bi-2212 one. It is also possible to find some Bi-free secondary phases (dark contrast, indicated by #1), which have been identified by EDX as Sr–Ca–Cu–O ones. The

---

![Fig. 1](image-url)
The amount of these secondary phases is increasing when the growth rate is raised, due to the destabilization of the solidification front, as it can be observed when comparing Fig. 1a (1 mm/h) with Fig. 1b (3 mm/h). In addition, it is also possible to find some scattered small CaO crystals in the as-grown samples, probably associated with local instabilities in the solidification front. Although it cannot be clearly seen on these micrographs, small intergrowths of Bi-2212 and Bi-2201 can be found close to the Bi-free secondary phases. In any case, as a result of the low growth rates used in this work, the major phase is always the Bi-2212 one, which is appearing as long grains (hundreds of microns), with their ab planes parallel to the growth direction. However, as a result of the strong thermal shock produced in these big size grains during the solidification, long cracks along the ab planes (marked as #2 in Fig. 1) appear. On the other hand, metallic Ag (light grey contrast, indicated by #3) is finely distributed inside the superconducting grains (see Fig. 1d). Furthermore, it can also be found as elongated grains filling the gaps between superconducting grains (see Fig. 1c). When the samples are annealed, no noticeable changes have been detected. Cracks are still easily found between Bi-2212 grains and only a small decrease in the amount of secondary phases is observed.

This last feature is confirmed by the powder XRD patterns performed in the as-grown and annealed samples. In Fig. 2, representative patterns for the as-grown and annealed samples prepared at 3 mm/h are presented. As it can be clearly seen in the figure, only small differences appear between both XRD patterns. At first sight, it is possible to see that the Bi-2212 is the major phase (peaks indicated by an inverted triangle in the figure [17]). On the other hand, the identification of the main peak of Bi-2201 phase [17] at \( \sim 29.7^\circ \) (marked with black diamond) with very small intensity, clearly indicates the low content of this phase. This is in agreement with the microstructural features discussed previously. Moreover, the peak appearing at around 38.2\(^\circ\) corresponds to the (111) diffraction plane of metallic Ag (marked as number sign). Finally, the symbol asterisk identifies the Bi-free secondary phase [18] which is decreasing after the thermal treatment. The main differences found in these patterns are due to the preferential orientation of the grains, as can be deduced from the variation observed in the relative intensities of the (00l) peaks. This effect can be associated with the samples preparation which can induce different preferential grain orientations in the powdered samples.

The electrical characteristics of the samples both, as-grown and annealed, are displayed in Table 1. As it is reflected in these data, all the samples show a similar \( T_C \), indicating that as-grown and annealed samples possess, approximately, the same oxygen content in the Bi-2212 grains, suggesting that the oxygenation thermal treatment is unnecessary in samples grown at these low rates. In all the cases, the samples display a metallic behavior at

| Growth rate | As-grown | | | After annealing | | |
|-------------|----------|----------|----------|----------------|----------|----------|
| \( T_C \) (K) | \( \sim 90.5 \) | \( \sim 90.5 \) | \( \sim 90.5 \) | \( \sim 90.5 \) | \( \sim 90.5 \) | \( \sim 90.5 \) |
| \( I_C \) (A) | 32.3 | 36.5 | 51 | 49.5 | 53.6 | 74 |
| \( d \) (mm) | 2.04 | 2.04 | 2.04 | 2.00 | 2.00 | 2.00 |
| \( J_C \) (A/cm\(^2\)) | 988 | 1,116 | 1,651 | 1,576 | 1,707 | 2,357 |
temperatures well above the transition one, as it is expected for Bi-2212 superconductors.

When considering the critical current intensities, it can be observed that higher growth rates produce higher $I_C$. This effect is related with the bigger grain sizes obtained with the lower growth speeds. These larger grain sizes promote the formation of higher thermal stresses and, as a consequence, the formation of bigger cracks. Moreover, after the thermal treatment, a slight raise in $I_C$ can be observed, which is clearly indicating that the annealing process has not been able to totally remove the cracks. In spite of the presence of these remaining cracks, an $I_C$ raise of about 50 % has been reached in all the cases. As can be regarded in Table 1 and in Fig. 3, $I_C$ is increasing with the growth speed. Moreover, the annealing process lead to higher $I_C$ values compared with the as-grown ones, but keeping the same trend (higher growth speed led to higher $I_C$ values), confirming the previous discussions about $I_C$ evolution. Finally, the obtained $I_C$ in these samples grown at low rates, even after the thermal treatments, are far lower than the obtained in previously reported data on Bi-2212/Ag composites grown at higher speeds [14] which avoid cracks formation.

4 Conclusions

$\text{Bi}_{2.02}\text{Sr}_{2.02}\text{Ca}_{0.98}\text{Cu}_{1.99}\text{O}_x/\text{2.9 wt \% Ag}$ ceramics were successfully grown through a LFZ process at very low rates (1, 3, and 5 mm/h). After the growth processes, all the samples are mainly composed by large and well-aligned Bi-2212 grains. The Ag has been found as small precipitates inside the grains and, in some cases, as elongated particles between the Bi-2212 grains. As a result of the cracks formed between the superconducting grains, $I_C$ values are between 1,000 A/cm$^2$ (1 mm/h) and 1,500 A/cm$^2$ (5 mm/h). After annealing process, the cracks were only partially removed, leading to an increase of about 50 % on the $I_C$. In any case, these low growth rates can be used to obtain single grains in an easy and quick manner.
