A WEYL ENTROPY OF PURE SPACETIME REGIONS

FRANCESCO BELGIORNO AND GIOVANNI CATINO

Abstract. We focus on the Penrose’s Weyl Curvature Hypothesis in a general framework encompassing many specific models discussed in literature. We introduce a candidate density for the Weyl entropy in pure spacetime perfect fluid regions and show that it is monotonically increasing in time under very general assumptions. Then we consider the behavior of the Weyl entropy of compact regions, which is shown to be monotone in time as well under suitable hypotheses, and also maximal in correspondence with vacuum static metrics. The minimal entropy case is discussed too.

Key Words: Weyl entropy, Pure spacetimes, Weyl Curvature Hypothesis

1. Introduction

Let \((X, \gamma)\) be a four-dimensional smooth connected Lorentzian manifold with signature \((-,+,+,+).\) We will say that \((X, \gamma)\) is a spacetime if the metric \(\gamma\) satisfies the Einstein equation

\[ R_{\alpha\beta} - \frac{1}{2} R \gamma_{\alpha\beta} = T_{\alpha\beta} \]

where \(R_{\alpha\beta}, R\) denote the Ricci and the scalar curvature of \(\gamma\) and \(T_{\alpha\beta}\) is a symmetric two tensor. The tensor \(T\) is referred as the stress-energy tensor. When \(T \equiv 0\) we will say \((X, \gamma)\) is a vacuum spacetime and the Einstein equation reads

\[ R_{\alpha\beta} - \frac{1}{2} R \gamma_{\alpha\beta} = 0 \]

or equivalently

\[ R_{\alpha\beta} = 0. \]

By the standard decomposition of the curvature tensor \(R_{\alpha\beta\gamma\delta}\) of the metric \(\gamma,\) the geometry of a spacetime is completely determined by its Weyl curvature \(W_{\alpha\beta\gamma\delta}\) (and the stress-energy tensor). More precisely, the Riemann curvature tensor of a spacetime satisfying \((1.1)\) is given by

\[ R_{\alpha\beta\gamma\delta} = W_{\alpha\beta\gamma\delta} + \frac{1}{2} (T_{\alpha\gamma\beta\delta} + T_{\delta\beta\gamma\alpha} - T_{\gamma\alpha\beta\delta} - T_{\delta\alpha\gamma\beta}) - \frac{T}{3} (\gamma_{\alpha\gamma} \gamma_{\beta\delta} - \gamma_{\alpha\delta} \gamma_{\beta\gamma}) \]

where \(T := \text{trace}(T) = \gamma^{\alpha\beta} T_{\alpha\beta},\) and thus it is natural to observe all the geometrical/physical properties of the space time arise from the Weyl and the stress-energy tensors.
The original Weyl Curvature Hypothesis by Roger Penrose [22] represents a still unproven conjecture about the entropic contribution of the gravitational field to the overall entropy of the Universe. The naive idea can be expressed as follows: according to Penrose, the entropy increase associated with the second law of thermodynamics is hardly compatible with the fact that, at the Big Bang, the Universe itself was in a uniform state of thermal equilibrium, which means that entropy was maximal. Penrose’s hypothesis is that only the matter field degrees of freedom (dof) were in equilibrium, whereas the dof associated with the gravitational field were not, and could maintain their very low entropy content for a long time, until the formation of galaxies and stars, because of the weakness of the gravitational interaction. There is a naive suggestion about the possibility to describe qualitatively the entropy of the gravitational dof, which consists in distinguishing two different contributions to the Riemann curvature as given in (1.3): on the one hand, there is the Ricci contribution, which is directly determined by the Einstein equations, and is then related to non-gravitational dof; on the other hand, there is a purely gravitational contribution, which is associated with the Weyl tensor. The Weyl Curvature Hypothesis amounts to hypothesizing that the Weyl curvature is zero at the initial singularity (Big Bang), to be compared with a divergent Ricci curvature. The hypothesis in itself does not determine a specific expression for the gravitational entropy in terms of the Weyl curvature tensor. There is a number of proposals in the physical literature, which take into account specific models, mainly of cosmological nature. Several proposals involve ratios between scalar functions of the Weyl tensor and scalar function of other curvature invariants, like e.g. the Ricci tensor as in the original ansatz by Penrose. All proposal are in general applied to specific models. [14, 15, 13, 21, 24, 25, 16]. One important contribution in this field is represented by [9], where five conditions are prescribed for any good definition of gravitational entropy. For completeness, we recall them, with the same notation:

(E1) it should be nonnegative;
(E2) it should vanish only if the Weyl curvature tensor vanishes;
(E3) it should measure the local anisotropy of the free gravitational field;
(E4) it should reproduce the Bekenstein-Hawking entropy in the black hole case;
(E5) it should increase monotonically as structures form in the Universe.

See also the discussion at the end of this section. We sum up our main definition for our entropic function in what follows. We stress that our Weyl entropy $S$ (as well as $S^{pf}$) is not yet integrated over a region of space, i.e. is the entropy of an infinitesimal volume (with the correct measure).

Consider a globally hyperbolic spacetime (see Section 3 for details)

$$(X, \gamma) = (I \times M^3, -N^2 dt^2 + g).$$

At given point $(t, x) \in X$ we define the Weyl entropy $S = S(t, x)$ as

$$S := \frac{|W_{\alpha\beta\gamma\delta}|_{\gamma}}{|R_{\alpha\beta\gamma\delta}|_{\gamma}} \sqrt{g}.$$
Figure 1. A picture of a Weyl Entropic Electric/Magnetic Regions of spacetime. Each region is given by the union of perfect fluid electric/magnetic regions with given parameters $k_i, \alpha_i$. 

where $R_{\alpha\beta\gamma\delta} \neq 0$ and $S = 1$ where $R_{\alpha\beta\gamma\delta} = 0$. Here $\bar{\gamma} = N^2 dt^2 + g$ is the Riemannian metric associated to $\gamma$ and $\sqrt{g}$ denotes the square-root of the determinant of the space metric $g$. In this paper we prove a monotonicity result for the related Weyl entropy

$$S_{\text{pf}} := S + s_{\text{crit}}\sqrt{g},$$

where $s_{\text{crit}}$ is an explicit nonnegative function depending on the parameters $k, \alpha$ of the perfect fluid electric region $\mathcal{PF}_k^E$. We refer to Section 7 for the precise definitions.

**Theorem 1.1.** On every $k$-perfect fluid electric $\alpha$-expanding region $\mathcal{PF}_k^E$ satisfying (7.1) the Weyl entropy $S_{\text{pf}}$ is monotonically increasing in time.

We have a similar result for magnetic regions.

**Theorem 1.2.** On every $k$-perfect fluid magnetic $\alpha$-expanding region $\mathcal{PF}_k^M$ the Weyl entropy $S$ is monotonically increasing in time.
We will call a \textit{Weyl Entropic Electric/Magnetic Region} of spacetime the union of $k$-perfect fluid electric/magnetic $\alpha$-expanding regions with different parameters $k_i, \alpha_i$ (see Figure 1). By Theorems 1.1 e 1.2, in these regions the Weyl entropy in increasing in time (E5). We also refer to the aforementioned regions as ‘pure spacetime regions’.

If the purely electric/magnetic character of the manifold is missing, there is no clear way to obtain a sensible increasing function of entropic type. It is not yet known how to study a mixed situation where the manifold is neither purely electric nor purely magnetic.

The parameter $k$ relates the pressure $P$ and the mass density $M$ of the fluid through the equation of state

$$P = (k - 1)M$$

and is standard in cosmology, where it is a constant labelling different epochs in the Universe evolution (see Figure 1). In the present picture, it is possible to allow for a dependence on time and space. A dependence on space-time coordinates can be allowed also for the further parameter $\alpha$, which measures the expansion and the homogeneity in space of the Universe (see Section 7 for the precise definitions).

From a physical point of view, there is not yet an unique way for identifying a gravitational entropy $S$, lacking a universally accepted and definitive quantum gravity theory. Notwithstanding, as discussed in [9], one can provide in different ways an ansatz for a putative entropy function for the gravitational field. In particular, the ratio involving the (Riemannian) modulus of the Weyl tensor and the (Riemannian) modulus of the Riemann tensor is interesting because it represents the relative weight of the Weyl curvature contribution with respect to the overall Riemannian curvature contribution, i.e. of the purely gravitational contribution to the curvature with respect to the sum of the gravitational and the matter field contributions, and is a pure number contained in the interval $[0, 1]$. There is not yet a specific statistical mechanical suggestion for such a specific ansatz, whose reliability can be judged only a posteriori. Furthermore, the density $S$ is only an ingredient of the physically relevant definition. It is \textit{a priori} not clear what definition for the physical entropy one should assume, as there is not yet a statistical mechanical framework for gravitational dof, and, on the other hand, an information theory inspired formula or even a thermodynamically inspired formula are difficult to be implemented. Clifton’s et al. attempt [9] belongs to the second framework, and requires to define a temperature field associated with every manifold which is taken into account. Even if this is a viable suggestion, it necessarily requires a (generally non-equilibrium) thermodynamics framework which is an ansatz again. Our choice is to ground our entropy candidate to the aforementioned density $S$, and a first step is represented by an averaging procedure over a space region $U$, which is common to other definitions [19] and produces what we could call $S^{\mu}_{U} \in [0, 1]$. Furthermore, we also postulate that our gravitational entropy is associated with the maximal entropy which can be associated with a region of space $U$. Such an entropy should be the black hole entropy. This idea is in turn related with the Bekenstein...
bound [2] (see also the review [6]). The naive ratio beyond this choice is the following: we can obtain what we could call ‘normalized entropy’ $S_n$, with $S_n \in [0, 1]$ as the ratio between $S$ and max$(S)$ (cf. also [23]). The same could be possible with an averaged entropy. Our further postulate is to assume that in the gravitational case one may choose max$(S)$ of a spatial region $U$ bounded by a surface $\Sigma$ as the area $A(\Sigma)$ of that surface (see Section 4). To be precise, for a compact space domain $U \in M^3$ (with two dimensional boundary $\Sigma := \partial U$), we define the Weyl entropy in $U$ as the averaged integral

$$S_U := \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U S = \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U |W_{\alpha\beta\gamma\delta}| \sqrt{g},$$

where $\text{Vol}_g(U) = \int_U \sqrt{g}$ and $\text{Area}(\Sigma)$ is the area of the boundary. Analogously, we define $S_{\text{pf}}^U$. As a consequence of Theorems 1.1 e 1.2 we can show the following (see also Section 10):

**Theorem 1.3.** On every $k$-perfect fluid electric $\alpha$-expanding region $\mathcal{P}\mathcal{F}_{k,\alpha}^E$ satisfying (7.1) and (10.1) the Weyl entropy in $U$ $S_U^\text{pf}$ is monotonically increasing in time. Moreover, maximal Weyl entropy in $U$ at time $t_0$ can only occur in a static vacuum spacetime region $[t_0, T) \times U$.

**Theorem 1.4.** On every $k$-perfect fluid magnetic $\alpha$-expanding region $\mathcal{P}\mathcal{F}_{k,\alpha}^E$ satisfying (10.1) the Weyl entropy in $U$ $S_U$ is monotonically increasing in time. Moreover, maximal Weyl entropy in $U$ at time $t_0$ can only occur in a flat (vacuum) spacetime region $[t_0, T) \times U$.

As to the list of properties stated in [9] and summarized above, (E1) is trivially satisfied by both $S$ and $S_{\text{pf}}$.

(E2) is automatically satisfied by $S$ but in the case of $S_{\text{pf}}$ one must also require $s_{\text{crit}}$, i.e. $\alpha = \frac{1}{3}$. Moreover, we can show that minimal Weyl entropy in $U$ $S_{\text{pf}}^U$ can only occur in a FLRW spacetime region $[0, T] \times U$ (see Section 10). We will avoid this unphysical situation assuming that the spacetime is non-homogeneous for $t > 0$.

As to (E3), local anisotropy implies the presence of a privileged direction in the orthogonal direction with respect to a congruence of timelike curves with unit tangent vectors. In other terms, a space section is isotropic at $x$ if there is no privileged direction in the tangent space at $x$. This is possible only for constant spatial curvature. As a consequence, any deviation from this condition ensures local anisotropy, which is easily implemented in our picture.

Property (E4) in line of principle would seem to be automatically satisfied e.g. for static black holes in vacuum. Actually, this identification would not be correct on the grounds of our hypothesis of expanding region, which, as a black hole is expected to form in a collapse process, is hardly compatible with the forming of a black hole itself. Still, it can be possible to justify the entropy of a cosmological horizon (if any), which is again of the Bekenstein-Hawking type, i.e. satisfies the well-known area law. In this sense, our claim is that our definition can satisfy the area law at least for cosmological horizons. In other terms, our constructive ansatz allows us to match by construction and with a suitable choice of a proportionality constant condition (E4) of [9].
As a consequence of the previous results, property (E5) is satisfied in pure spacetime regions (i.e. purely electric/magnetic regions).

There are two further considerations which appear to be relevant to the present discussion. In agreement with the maximal character of entropy in equilibrium, we find that entropy is maximal for static vacuum solutions, i.e. in the case of metrics which can be considered equilibrium states of the geometry, which remain static (no further evolution). We think that it could be suitable introducing a further condition (E6): entropy is maximal in the case of static solutions in vacuum.

To conclude, it is worthwhile to observe that all aforementioned properties, apart for (E4), hold true also for the Weyl entropy in simply defined by

\[ \int_U S = \int_U \frac{|W_{a\beta\gamma\delta}|}{|R_{a\beta\gamma\delta}|} \sqrt{g}. \]

2. Preliminaries on the Curvature of Spacetimes

Let \((X, \gamma)\) be a spacetime. We will denote by \(D\) the covariant derivative with respect to \(\gamma\) and \(R_{a\beta\gamma\delta}, \alpha, \beta, \gamma, \delta = 0, 1, 2, 3\), its curvature tensor. We recall the following decomposition of the curvature tensor (see [4, 7])

\[ R_{a\beta\gamma\delta} = W_{a\beta\gamma\delta} + \frac{1}{2} (R_{a\gamma\beta\delta} - R_{a\delta\gamma\beta} + R_{\beta\delta\gamma\alpha} - R_{\beta\gamma\alpha\delta} - \frac{R}{6} (\gamma_{a\gamma\beta\delta} - \gamma_{a\delta\gamma\beta}) \]

where \(W_{a\beta\gamma\delta}, R_{a\beta}\) and \(R\) denote the Weyl, Ricci and scalar curvature of \(\gamma\), respectively. The Einstein equation of spacetime states that

\[ R_{a\beta} - \frac{1}{2} R \gamma_{a\beta} = T_{a\beta}. \]

Tracing the equation we obtain

\[ R = -T \]

where \(T = \gamma^{a\beta} T_{a\beta}\) is the trace of the stress-energy tensor. Thus

(2.1) \[ R_{a\beta} = T_{a\beta} - \frac{1}{2} T \gamma_{a\beta}. \]

Therefore, one has

(2.2) \[ R_{a\beta\gamma\delta} = W_{a\beta\gamma\delta} + \frac{1}{2} \left( T_{a\gamma\beta\delta} - T_{a\delta\beta\gamma} + T_{\beta\delta\gamma\alpha} - T_{\beta\gamma\alpha\delta} - \frac{T}{3} (\gamma_{a\gamma\beta\delta} - \gamma_{a\delta\gamma\beta}) \right) \]

From the Einstein equation we have that the stress-energy tensor is diverge free, i.e.

(2.3) \[ D_a T_{a\beta} = 0. \]

We will use the usual notation to denote the norm of a \((0, r)\)-tensor \(P\) with respect to the spacetime metric \(\gamma\), namely

\[ |P|^2 := \gamma^{i_1 m_1} \cdots \gamma^{i_r m_r} P_{i_1 \cdots i_r} P_{m_1 \cdots m_r}. \]
Note that one has
\[ |R_{\alpha\beta}|^2 = |T_{\alpha\beta}|^2, \]
and
\[
|R_{\alpha\beta\gamma\delta}|^2 = |W_{\alpha\beta\gamma\delta}|^2 + 2|R_{\alpha\beta}|^2 - \frac{1}{3}R^2 = |W_{\alpha\beta\gamma\delta}|^2 + 2|T_{\alpha\beta}|^2 - \frac{1}{3}T^2
\]
where
\[
|W_{\alpha\beta\gamma\delta}|^2 = |A_{\alpha\beta\gamma\delta}|^2 + 2|T_{\alpha\beta}|^2 - \frac{1}{3}T^2
\]
and the four tensor \( A \) is computed from the so called Schouten tensor (see, for instance, [7, Chapter 1])
\[ A_{\alpha\beta} := R_{\alpha\beta} - \frac{R}{6}g_{\alpha\beta} \]
and is given by
\[ A_{\alpha\beta\gamma\delta} = \frac{1}{2}(A_{\alpha\gamma\beta\delta} - A_{\alpha\delta\gamma\beta} + A_{\beta\delta\gamma\alpha} - A_{\beta\gamma\alpha\delta}). \]

The Cotton tensor is given by
\[
C_{\alpha\beta\gamma} := D_{\gamma}A_{\alpha\beta} - D_{\beta}A_{\alpha\gamma}
\]
\[
= D_{\gamma}R_{\alpha\beta} - D_{\beta}R_{\alpha\gamma} - \frac{1}{6}(D_{\gamma}R_{\alpha\beta} - D_{\beta}R_{\gamma\alpha})
\]
\[
= D_{\gamma}T_{\alpha\beta} - D_{\beta}T_{\alpha\gamma} - \frac{1}{3}(D_{\gamma}T_{\alpha\beta} - D_{\beta}T_{\gamma\alpha})
\]

We recall also the following useful formula (a second bianchi identity for the Weyl tensor, see [7, Chapter 2])
\[
D_{\eta}W_{\alpha\beta\gamma\delta} + D_{\gamma}W_{\alpha\beta\delta\eta} + D_{\delta}W_{\alpha\beta\eta\gamma} = \frac{1}{2}(C_{\alpha\delta\gamma\beta} + C_{\alpha\gamma\beta\delta} + C_{\alpha\beta\delta\gamma} - C_{\alpha\beta\gamma\delta})
\]
\[ - \frac{1}{2}(C_{\beta\delta\gamma\alpha} + C_{\beta\gamma\alpha\delta} + C_{\beta\alpha\delta\gamma}) \]
which will be crucial to compute the evolution in time of the Weyl curvature.

### 3. Globally Hyperbolic Spacetimes

Let \((X, g)\) be a spacetime. It is well known that the causal structure of an arbitrary spacetime can have undesirable pathologies. All these can be avoided by postulating the existence of a Cauchy hypersurface \( M^3 \) in \( X \), i.e. a hypersurface \( M^3 \) with the property that any causal curve intersects it at precisely one point. Spacetimes with this property are called \textit{globally hyperbolic} and we will always assume that the space time is the \textit{maximal} smooth Cauchy development of initial data on the Cauchy hypersurface \( M^3 \) (see [26] and [17, Chapter 7]). Such spacetimes are in particular stable causal, i.e. they allow the existence of a globally defined differentiable function \( t \) whose gradient \( Dt \) is everywhere time-like. To
be more general, we will consider also the case where the gradient $D_t$ could be light-like on some subsets of $X$. In this case we will say that the spacetime is \textit{almost globally hyperbolic}. This allows the presence of possible horizons. We call $t$ a \textit{time function} and the foliation given by its level surfaces a $t$-foliation. We denote by $T$ the future directed unit normal to the foliation. Topologically, a space-time foliated by the level surfaces of a time function is diffeomorphic to a product manifold $I \times M^3$ where $I = [0, T)$ and $M^3$ is a three-dimensional smooth manifold. In fact the spacetime can be parametrized by points on the slice $t = 0$ by following the integral curves of $D_t$. Relative to this parametrization the spacetime metric $\gamma$ takes the form

$$\gamma = -N^2(t, x) dt^2 + g_{ij}(t, x) dx^i dx^j$$

where $t \in I$ and $x = (x^1, x^2, x^3)$ are arbitrary coordinates on the slice $t = 0$. The function $N(t, x) = \gamma(D_t, D_t)^{-1/2}$ is called the \textit{lapse function} of the foliation and $g_{ij}$ its first fundamental form. We will denote by $M_t = \{t\} \times M^3$ the leaves of the foliation. The unit normal to the foliation $T$ is given by $T = N^{-1} \partial_t$. The second fundamental form $h$ of the foliation is given by

$$h_{ij} = -\frac{1}{2N} \partial_t g_{ij}.$$  

We denote by $\nabla$ the covariant derivative on the leaves $M_t$ and by $R_{ijkl}$, $R_{ij}$ and $R$ its Riemann, Ricci and scalar curvature, respectively. Since $M^3$ is three-dimensional, the Riemann tensor of $g$ can be totally recovered from the Ricci tensor, and we have the decomposition (see for instance [7])

$$R_{ijkl} = (R_{ik}g_{jl} - R_{il}g_{jk} + R_{jl}g_{ik} - R_{jk}g_{il}) - \frac{R}{2} (g_{ik}g_{jl} - g_{il}g_{jk}).$$

By classical formulas, the second fundamental form $h$, the lapse function $N$ and the curvature $R_{ijkl}$ of the foliation are connected to the spacetime curvature tensor $R_{\alpha\beta\gamma\delta}$ by the following (for instance, see [8])

$$R_{ijkl} = R_{ijkl} + h_{ik}h_{jl} - h_{il}h_{jk},$$

$$R_{Tijk} = \nabla_j h_{ik} - \nabla_k h_{ij},$$

$$NR_{T;j} = \partial_i h_{ij} + Nh_{ik}h_{kj} + \nabla_i \nabla_j N,$$

where $R_{ijkl} = R(\partial_i, \partial_j, \partial_k, \partial_l)$, $R_{Tijk} = R(T, \partial_i, \partial_j, \partial_k)$ and $R_{T;j} = R(T, \partial_i, T, \partial_j)$ are the components of the spacetime curvature relative to arbitrary coordinates on $M^3$. Tracing the previous equations we get

$$NR_{ij} = NR_{ij} - \partial_k h_{ij} + N H h_{ij} - 2Nh_{il}h_{jl} - \nabla_i \nabla_j N,$$

$$R_{Tj} = \nabla_j H - \nabla_k h_{jk},$$

$$NR_{TT} = \partial_t H - N|h|^2 + \Delta N,$$
where \( H \) denotes the mean curvature of the foliation, namely \( H = g^{ij}h_{ij} \). Imposing the Einstein equation (1.1) we obtain

\[
N \left( \mathcal{T}_{ij} - \frac{1}{2} \mathcal{T} g_{ij} \right) = NR_{ij} - \partial_t h_{ij} + NH h_{ij} - 2N h_{il}h_{jl} - \nabla_i \nabla_j N
\]

(3.4)

\[
\mathcal{T}_{Tj} = \nabla_j H - \nabla_k h_{jk}
\]

\[
N \left( \mathcal{T}_{TT} + \frac{1}{2} \mathcal{T} \right) = \partial_t H - N|h|^2 + \Delta N.
\]

In particular, tracing these equations, we discover the so called Einstein constrained equations for the foliation of a spacetime

\[
R + H^2 - |h|^2 = 2\mathcal{T}_{TT}
\]

(3.5)

\[
\nabla_j H - \nabla_k h_{jk} = \mathcal{T}_{Tj}.
\]

Using (2.2), since

\[
\gamma_{ij} = g_{ij}, \quad \gamma_{Tt} = 0 \quad \text{and} \quad \gamma_{TT} = -1,
\]

we have

\[
R_{ijkl} = W_{ijkl} + \frac{1}{2} \left( \mathcal{T}_{ik} g_{jl} - \mathcal{T}_{il} g_{jk} + \mathcal{T}_{jl} g_{ik} - \mathcal{T}_{jk} g_{il} \right) - \frac{\mathcal{T}}{3} (g_{ik} g_{jl} - g_{il} g_{jk})
\]

\[
R_{Tijk} = W_{Tijk} + \frac{1}{2} \left( \mathcal{T}_{Tj} g_{ik} - \mathcal{T}_{Tk} g_{ij} \right)
\]

\[
R_{TiTj} = W_{TiTj} + \frac{1}{2} \left( \mathcal{T}_{TT} g_{ij} - \mathcal{T}_{ij} \right) + \frac{\mathcal{T}}{3} g_{ij}
\]

and, from (3.3), we obtain

\[
W_{ijkl} = -\frac{1}{2} \left( \mathcal{T}_{ik} g_{jl} - \mathcal{T}_{il} g_{jk} + \mathcal{T}_{jl} g_{ik} - \mathcal{T}_{jk} g_{il} \right)
\]

\[
+ \left( R_{ik} g_{jl} - R_{il} g_{jk} + R_{jl} g_{ik} - R_{jk} g_{il} \right)
\]

\[
- \frac{3R - 2\mathcal{T}}{6} (g_{ik} g_{jl} - g_{il} g_{jk}) + h_{ik} h_{jl} - h_{il} h_{jk}
\]

(3.7)

\[
W_{Tijk} = -\frac{1}{2} \left( \mathcal{T}_{Tj} g_{ik} - \mathcal{T}_{Tk} g_{ij} \right) + \nabla_j h_{ik} - \nabla_k h_{ij}
\]

(3.8)

\[
NW_{TiTj} = -\frac{1}{2} N \left( \mathcal{T}_{TT} g_{ij} - \mathcal{T}_{ij} \right) - \frac{\mathcal{T}}{3} N g_{ij} + \partial_t h_{ij} + Nh_{ik} h_{kj} + \nabla_i \nabla_j N,
\]

(3.9)

We have the following formulas relating the Weyl tensor components.

**Lemma 3.1.** Let \((X, \gamma)\) be a globally hyperbolic spacetime. Then

\[
W_{TiTj} = g^{kl}W_{kil} + \mathcal{T}_{Tj} g_{ik} - \mathcal{T}_{Tk} g_{ij} + W_{TjTi} g_{ik} - W_{TjTk} g_{il} + \mathcal{T}_{Ti} g_{kl} - \mathcal{T}_{Tl} g_{kl} + \mathcal{T}_{Tj} g_{kl} + \mathcal{T}_{Tk} g_{ij}.
\]

**Proof.** Since \( W \) is trace free, one has

\[
0 = \gamma^{\alpha \beta} W_{\alpha i \beta j} = -W_{TiTj} + g^{kl}W_{kilj}.
\]
Thus \( \varepsilon \) parts, the Weyl tensor \( W \) and in analogy to the decomposition of the Maxwell tensor into electric and magnetic field one has

\[
N \left( T_{ij} - \frac{1}{2} T g_{ij} \right) = NR_{ij} - \partial_i h_{ij} + NH h_{ij} - 2Nh_i h_{jl} - \nabla_i \nabla_j N
R + H^2 - |h|^2 = 2T_{TT}.
\]

Hence, from (3.9) we get

\[
(3.10) \quad W_{T^i T^j} = R_{ij} - \frac{1}{2} T_{ij} - \frac{3R - 2T}{12} g_{ij} - \frac{H^2 - |h|^2}{4} g_{ij} + Nh_{ij} - h_{il} h_{jl}.
\]

Thus, from (3.7) one obtain

\[
W_{ijkl} = (W_{T^i T^k} g_{jl} - W_{T^i T^l} g_{jk} + W_{T^j T^l} g_{ik} - W_{T^j T^k} g_{il})
- \frac{|h|^2 - H^2}{2} (g_{ik} g_{jl} - g_{il} g_{jk}) + h_{ik} h_{jl} - h_{ij} h_{jk}
+ (h_{ip} h_{kp} g_{jl} - h_{ip} h_{lp} g_{jk} + h_{jp} h_{lp} g_{ik} - h_{jp} h_{kp} g_{il})
- H (h_{ik} g_{jl} - h_{il} g_{jk} + h_{jl} g_{ik} - h_{jk} g_{il})
\]

Setting

\[
Z_{ijkl} := \frac{|h|^2 - H^2}{2} (g_{ik} g_{jl} - g_{il} g_{jk}) + h_{ik} h_{jl} - h_{ij} h_{jk}
+ (h_{ip} h_{kp} g_{jl} - h_{ip} h_{lp} g_{jk} + h_{jp} h_{lp} g_{ik} - h_{jp} h_{kp} g_{il})
- H (h_{ik} g_{jl} - h_{il} g_{jk} + h_{jl} g_{ik} - h_{jk} g_{il}),
\]

Take a basis diagonalizing \( h \), one has \( h_{ij} = \mu_i \delta_{ij} \) and for \( i \neq j \neq k \) we get

\[
Z_{ijij} := \frac{|h|^2 - H^2}{2} + \mu_i \mu_j + \mu_i^2 + \mu_j^2 - H(\mu_i + \mu_j)
= \frac{1}{2} [(\mu_i + \mu_j + \mu_k)^2 - (\mu_i^2 + \mu_j^2 + \mu_k^2)] + \mu_i \mu_j + \mu_i^2 + \mu_j^2 - (\mu_i + \mu_j + \mu_k)(\mu_i + \mu_j)
= 2\mu_i \mu_j + \mu_i \mu_k + \mu_j \mu_k + \mu_i^2 + \mu_j^2 - (\mu_i + \mu_j + \mu_k)(\mu_i + \mu_j) = 0
\]

Thus \( Z \equiv 0 \) and the proof is completed. \( \square \)

Given a globally hyperbolic spacetime \((X, \gamma) = (I \times M^3, -N^2 dt^2 + g)\), being the vector field \( T \) a timelike unit vector, following the 1 + 3 covariant description of gravitational fields [10] and in analogy to the decomposition of the Maxwell tensor into electric and magnetic parts, the Weyl tensor \( W \) can also be decomposed into electric and magnetic parts as

\[
E_{\alpha\beta} = W_{\alpha\gamma\delta\beta} T^\gamma T^\delta, \quad H_{\alpha\beta} = \frac{1}{2} \varepsilon_{\alpha\gamma\delta\eta} W^{\delta\eta}_{\beta\gamma} T^\gamma T^\theta
\]

where \( \varepsilon_{\alpha\gamma\delta\eta} \) is the volume element. Using arbitrary coordinates on \( M^3 \), we get

\[
E_{ij} = W_{T^i T^j}, \quad E_{ij} = 0, \quad H_{ij} = \frac{1}{2} \varepsilon_{T^\delta T^\eta} W^{\delta\eta}_{jT} = \frac{1}{2} \varepsilon_{T^k T^l} W^{kl}_{jT}, \quad H_{iT} = 0.
\]
In particular, on a globally hyperbolic spacetime, $E$ vanishes if and only if $W^{TiTj} = 0$ locally, while $H$ vanishes if and only if $W^{Tijk} = 0$ locally. Spacetimes with zero electric part $E$ (or magnetic part $H$) are called in the literature Pure Electric (or Magnetic) spacetimes (see, for instance [20, 5, 18]).

We note that, one has

$$|W_{\alpha\beta\gamma\delta}|^2 = \frac{1}{4} (|E_{\alpha\beta}|^2 - |H_{\alpha\beta}|^2), \quad |W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2 = \frac{1}{4} (|E_{\alpha\beta}|^2 + |H_{\alpha\beta}|^2).$$

In particular, the quantity $W$ considered in [9] constructed from the so called Bel-Robinson tensor [3], coincides exactly with $|W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2$.

### 4. A Weyl Entropy

Throughout this section we will consider a globally hyperbolic spacetime

$$(X, \gamma) = (I \times M^3, -N^2 dt^2 + g)$$

as discussed in the previous section. On a generic spacetime the functions $|W_{\alpha\beta\gamma\delta}|^2$ can be negative somewhere. In fact, while the norm of a symmetric two tensor (such as the Ricci tensor) is always nonnegative, a simple computation (see Lemma 5.1) gives

$$|W_{\alpha\beta\gamma\delta}|^2 = -4|W^{TiTj}|^2 + 4|W^{Tijk}|^2 + |W^{ijkl}|^2 = -4|W^{TiTj}|^2 + 8|W^{Tijk}|^2.$$

We ask for the entropy to be measured from the Weyl tensor, to be nonnegative and to be zero if and only if the Weyl tensor vanishes. Thus we will consider the norm computed with respect to the Riemannian metric $\bar{\gamma}$ associated to $\gamma$, namely:

$$\bar{\gamma} := N^2 dt^2 + g.$$

Thus, we have

$$|W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2 = 4|W^{TiTj}|^2 + 8|W^{Tijk}|^2$$

which is nonnegative and vanishes if and only if $W = 0$. We give the following definition of Weyl entropy:

**Definition 4.1.** At given point $(t, x) \in X$ we define the Weyl entropy $S = S(t, x)$ as

$$S := \frac{|W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}}{|R_{\alpha\beta\gamma\delta}|_{\bar{\gamma}} \sqrt{g}},$$

where $R_{\alpha\beta\gamma\delta} \neq 0$ and $S = \sqrt{g}$ where $R_{\alpha\beta\gamma\delta} = 0$. Here $\sqrt{g}$ denotes the square-root of the determinant of the space metric $g$. We will call

$$s := \begin{cases} \frac{|W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}}{|R_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}} & \text{if } R \neq 0 \\ 1 & \text{if } R = 0 \end{cases}$$

the Weyl entropy density.
Given a compact space domain $U \subseteq M^3$ (with two dimensional smooth boundary $\Sigma := \partial U$), we define the *Weyl entropy* in $U$ as the averaged integral

$$S_U := \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U S = \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U s \sqrt{g},$$

where $\text{Vol}_g(U) = \int_U \sqrt{g}$ and $\text{Area}(\Sigma)$ is the two-dimensional Haussdorf area of the boundary, computed with respect to the metric induced by $g$ on $\Sigma$. By definition, $S_U \geq 0$, with equality if and only if the Weyl tensor vanishes on $U$. Moreover, from Lemma 5.1, we have

$$S_U \leq \text{Area}(\Sigma)$$

with equality if and only if the Ricci tensor of $\gamma$ vanishes. From the Einstein equation, this is equivalent to say that the stress-energy tensor $T$ vanishes (vacuum region). In particular we have the following characterization of space region with maximal Weyl entropy: the Weyl entropy in $U$, $S_U$, is maximal at a given time $t$ if and only if $T = 0$ on $\{t\} \times U$.

We stress again that, in the above definition, the appearance of the factor $\text{Area}(\Sigma)$ is an ansatz which is seemingly arbitrary, but it can be justified on the grounds of black hole thermodynamics, and is compatible with the conjecture that the maximal entropy for a region with boundary area $\text{Area}(\Sigma)$ is the black hole entropy, which is $A/4$, as well known. In this sense, in the definition we could also introduce a multiplicative constant $\zeta$ (with $\zeta = 1/4$ for static black holes), in such a way to implement fully the assumption (E4) of [9].

As well known, in thermodynamics the entropy is maximal for equilibrium states. Of course, it is not possible to associate the Weyl entropy with a thermodynamic entropy, even in a non-equilibrium framework, as the possibility to define a local temperature in a natural way is missing (cf. anyway the picture in [9]). Still, some ‘entropy-like’ properties can be identified. In fact, in Section 10, we show that the Weyl entropy related to region where there is monotonicity is maximal at some time, if and only if the region is a static vacuum solution, as if it were a real equilibrium entropy (an equilibrium state is a static one, and static solutions appear as sort of ‘equilibrium states of the geometry’).

In order to simplify the computations for the evolution of the Weyl entropy, we introduce the following quantity, where $A \neq 0$,

$$s^2 = \frac{|W_{\alpha\beta\gamma\delta}|^2_{\tilde{g}} |R_{\alpha\beta\gamma\delta}|_{\tilde{g}}^2}{|A_{\alpha\beta\gamma\delta}|_{\tilde{g}}^2},$$

where $\tilde{s}^2 := \frac{|W_{\alpha\beta\gamma\delta}|^2_{\tilde{g}}}{|A_{\alpha\beta\gamma\delta}|_{\tilde{g}}^2}$.

For reasons that will be clear in the rest of the computations, we will study the entropy $S$ on spacetimes $(X, \gamma)$ satisfying (locally) either

(H1) \hspace{1cm} \text{either} \hspace{1cm} W_{Tijk} \equiv 0
or

(H2) \[ W_{TiTj} \equiv 0. \]

As observed in the previous section, condition (H1) is equivalent for the spacetime to be Pure Electric (also called Coulomb like), while condition (H2) is equivalent for the spacetime to be Pure Magnetic (or Wave Like). From (4.1) it is clear that

\[
|W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}} = \begin{cases} |W_{\alpha\beta\gamma\delta}| & \text{if (H1) holds,} \\ -|W_{\alpha\beta\gamma\delta}| & \text{if (H2) holds.} \end{cases}
\]

Geometrically, from equation (3.8) there is an equivalence between condition (H1) and the second fundamental form \( h_{ij} \) to be a Codazzi tensor on the space slice \( M^3 \), whenever the stress-energy tensor is diagonal (e.g. perfect fluid case). In this case, sufficient conditions that imply (H1) are \( h_{ij} \equiv 0 \) (totally geodesic foliation, i.e. time-symmetric spacetime) or, more in general, \( h_{ij} \equiv \frac{H}{3} g_{ij} \) (totally umbilical foliation). A sufficient condition is also \( \nabla h \equiv 0 \), i.e. parallel second fundamental form. Many examples satisfying this assumption are well studied (for instance Bianchi type I, Lemaitre-Tolman [9, 16]). Examples of spacetime satisfying (H2) can be found in [11, 1].

5. Pure Electric Spacetimes

We will need the following formulas.

**Lemma 5.1.** Let \((X, \gamma)\) be a globally hyperbolic spacetime. Then the following identity hold

\[
|W_{\alpha\beta\gamma\delta}|^2 = -4|W_{Tijk}|^2 + 8|W_{TiTj}|^2,
\]

\[
|A_{\alpha\beta\gamma\delta}|^2 = -4|A_{Tijk}|^2 + 4|A_{TiTj}|^2 + |A_{ijkl}|^2
\]

\[
|R_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2 = |W_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2 + |A_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2.
\]

and, if \( A_{Tijk} = 0 \), then

\[
|A_{\alpha\beta\gamma\delta}|_{\bar{\gamma}}^2 = |A_{\alpha\beta\gamma\delta}|^2.
\]

In particular, if \((X, \gamma)\) satisfies (H1), then

\[
|W_{\alpha\beta\gamma\delta}|^2 = 8|W_{TiTj}|^2.
\]

**Proof.** One has

\[
|W_{\alpha\beta\gamma\delta}|^2 = -4|W_{Tijk}|^2 + 4|W_{TiTj}|^2 + |W_{ijkl}|^2.
\]

Using Lemma 3.1 we get

\[
|W_{ijkl}|^2 = 4|W_{TiTj}|^2,
\]
Lemma 5.2. Let \( R_{\alpha\beta\gamma\delta} \) and the last formula holds. Moreover, from the definition of covariant derivative and condition (H1) implies

\[
D_{\gamma} W_{\alpha\beta\gamma\delta} = 2 \left( h_{\gamma k} W_{T_j T_l} - h_{\gamma k} W_{T_l T_j} + h_{\gamma l} W_{T_j T_k} - h_{\gamma l} W_{T_k T_j} \right)
+ h_{l p} \left( W_{T_j T_p} g_{ik} - W_{T_p T_j} g_{jk} \right) + h_{k p} \left( W_{T_l T_p} g_{jl} - W_{T_p T_l} g_{lj} \right)
+ \frac{1}{2} \left( C_{l T} g_{jk} + C_{T k} g_{jl} - C_{j T} g_{ik} + C_{j T k} g_{il} \right),
\]

\[
D_{l} W_{ij k T} = 2 \left( h_{l j} W_{T_i T_k} - h_{l j} W_{T_k T_i} \right) + h_{l p} \left( W_{T_j T_p} g_{ik} - W_{T_p T_j} g_{jk} \right),
\]

\[
D_{T} W_{T_i T_j} = 2 H W_{T_i T_j} - 2 h_{i j} W_{T_i T_l} - h_{i j} W_{T_l T_i} + h_{k j} W_{T_k T_p} g_{ij} - \frac{1}{2} C_{T j} T_i .
\]

Proof. From the second bianchi identity \((2.8)\) we have

\[
D_{T} W_{i j k l} = - D_{k} W_{i j l T} - D_{l} W_{i j k T} + \frac{1}{2} \left( C_{i l} T g_{jk} + C_{l i} T g_{jl} - C_{j l} T g_{ik} + C_{j l i} T g_{il} \right)
= D_{l} W_{i j k T} - D_{k} W_{i j l T} + \frac{1}{2} \left( C_{i l} T g_{jk} + C_{l i} T g_{jl} - C_{j l} T g_{ik} + C_{j l i} T g_{il} \right).
\]

Moreover, from the definition of covariant derivative and condition (H1) implies

\[
D_{l} W_{i j k T} = \partial_{l} W_{i j k T} - \Gamma^{T}_{l i} W_{T_j k T} - \Gamma^{T}_{l j} W_{T_i k T} - \Gamma^{0 T}_{l j k T} W_{i j l T} + \Gamma^{0 T}_{l j k T} W_{i j l p},
\]

\[
= \Gamma^{T}_{l i} W_{T_j k T} - \Gamma^{T}_{l j} W_{T_i k T} - \Gamma^{0 T}_{l i k T} W_{i j l T}
= - h_{l j} W_{T_i T_k} + h_{j l} W_{T_i T_k} + h_{l p} W_{i j k p},
\]

where we have used the formulas

\[
\Gamma^{0}_{l i} = - \frac{1}{2 N^2} \partial_{l} (N^2) = - \frac{\partial_{l} N}{N},
\]

\[
\Gamma^{T}_{l i} = \frac{1}{2} \partial_{l} (N^2) = N \partial_{l} N,
\]

\[
\Gamma^{j l}_{i} = \frac{1}{2} g^{j k} \partial_{i} g_{k l} = - N h_{i j},
\]

\[
\Gamma^{l}_{l j} = \frac{1}{2 N^2} \partial_{l} g_{i j} = - \frac{1}{N} h_{i j},
\]

\[
\Gamma^{l}_{l j} = \Gamma^{k}_{l j},
\]

where \( \Gamma^{k}_{i j} \) are the Christoffel symbols of the metric \( g \). In particular, we have

\[
\Gamma^{T}_{l i} = - h_{i j} \quad \text{and} \quad \Gamma^{T}_{l j} = - h_{i j}.
\]
Rewriting the last equations we have proved that

\begin{equation}
D_T W_{ijkl} = -h_{il} W_{TjTk} + h_{jl} W_{TiiT} + h_{lp} W_{ijkp} + h_{ik} W_{TjTl} - h_{jk} W_{TiiT} - h_{lp} W_{ijlp} + \frac{1}{2} (C_{ilTgjk} + C_{Tikgjl} - C_{jTlgik} + C_{jTlgil}),
\end{equation}

\begin{equation}
D_l W_{ijkT} = -h_{il} W_{TjTk} + h_{jl} W_{TiTk} + h_{lp} W_{ijkp}.
\end{equation}

On the other hand, by Lemma 3.1 one has

\begin{equation}
D_T W_{TiiT} = D_T \left( g^{kl} W_{kilj} \right)
= \left( D_T \gamma^{kl} \right) W_{kilj} + g^{kl} D_T W_{kilj}
= g^{kl} (-h_{kj} W_{TiiT} + h_{lj} W_{TKTl} + h_{lp} W_{kijp} + h_{kl} W_{TiiT} - h_{il} W_{TKTl} - h_{lp} W_{kijp}) - \frac{1}{2} C_{ijT},
\end{equation}

i.e.

\begin{equation}
D_T W_{TiiT} = HW_{TiiT} - h_{il} W_{TiTT} + h_{kp} W_{kijp} - \frac{1}{2} C_{ijT}.
\end{equation}

Moreover

\begin{equation}
h_{lp} W_{ijkp} = h_{lp} \left( W_{TiiTk} g_{jp} - W_{TiTT} g_{ij} + W_{TjTl} g_{ik} - W_{TijTk} g_{il} \right)
= h_{jl} W_{TiiTk} - h_{il} W_{TjTk} + h_{lp} W_{TjTl} g_{ik} - h_{lp} W_{TiTT} g_{jk},
\end{equation}

and

\begin{equation}
h_{kp} W_{kijp} = h_{kp} \left( W_{TKTl} g_{ij} - W_{TkTl} g_{kp} + W_{TiiT} g_{lk} - W_{TijTk} g_{ik} \right)
= h_{kp} W_{TkTl} g_{ij} - h_{ik} W_{TjTk} - h_{jk} W_{TiTk} + HW_{TiiT}.
\end{equation}

Substituting in (5.2), (5.3) and (5.4) (and using again Lemma 3.1) we get

\begin{equation}
D_T W_{ijkl} = 2 \left( h_{ik} W_{TjTl} - h_{jk} W_{TiiT} + h_{jl} W_{TiiTk} - h_{il} W_{TjTk} \right)
+ h_{lp} \left( W_{TjTl} g_{ik} - W_{TiiTk} g_{jk} \right) + h_{kp} \left( W_{TiTT} g_{ij} - W_{TijTk} g_{il} \right)
+ \frac{1}{2} (C_{ilTgjk} + C_{Tikgjl} - C_{jTlgik} + C_{jTlgil}),
\end{equation}

\begin{equation}
D_l W_{ijkT} = 2 \left( h_{jl} W_{TiiTk} - h_{il} W_{TjTk} \right) + h_{lp} \left( W_{TjTl} g_{ik} - W_{TiiTk} g_{jk} \right),
\end{equation}

\begin{equation}
D_T W_{TiiT} = 2 HW_{TiiT} - 2 h_{il} W_{TjTl} - h_{jl} W_{TiTT} + h_{kp} W_{TkTl} g_{ij} - \frac{1}{2} C_{ijT}.
\end{equation}

\(\square\)

As a consequence, we obtain the following formula:
**Proposition 5.3.** Let \((X, \gamma)\) be a globally hyperbolic spacetime satisfying \((H1)\). Then
\[
\frac{1}{2}D_{T}W_{a\beta\gamma\delta} = 16H|W_{TTij}|^2 - 24h_{jl}W_{TTij}W_{TTil} - 4C_{ijT}W_{TTij},
\]
where \(C\) is the Cotton tensor of \(\gamma\).

**Proof.** From Lemma 5.1 one has
\[
\frac{1}{2}D_{T}W_{a\beta\gamma\delta} = 8(D_{T}W_{TTij})W_{TTij}.
\]
Moreover
\[
D_{T}W_{TTij} = g^{kl}W_{klij} = \left( g^{kl}D_{T}W_{kl} \right) + \frac{1}{2} (C_{ijT} - C_{ijT} + C_{ijT}).
\]
where we have used Lemma 5.2. Thus
\[
(D_{T}W_{TTij})W_{TTij} = 2H|W_{TTij}|^2 - 3h_{jl}W_{TTij}W_{TTil} - \frac{1}{2}C_{ijT}W_{TTij}
\]
and the thesis follows. \(\square\)

6. Pure Electric Spacetimes: Perfect Fluids

Take a *perfect fluid* stress-energy tensor given by
\[
\mathcal{T}_{TT} = M, \quad \mathcal{T}_{Ti} = 0, \quad \mathcal{T}_{ij} = Pg_{ij},
\]
where \(M = M(t, x)\) is the mass density and \(P = P(t, x)\) the pressure of the fluid. One has
\[
\mathcal{T} := \gamma^{\alpha\beta}\mathcal{T}_{\alpha\beta} = 3P - M
\]
and
\[
|\mathcal{T}_{\alpha\beta}|^2 = M^2 + 3P^2.
\]
Note that, from (2.3) one has
\[
0 = -D_{T}\mathcal{T}_{TT} + D_{i}\mathcal{T}_{iT} = -D_{T}M - \Gamma_{TT}^{i}T_{TT} - \Gamma_{iT}^{j}\mathcal{T}_{ij} = -D_{T}M + HM + HP,
\]
i.e.
\[ D_T M = (M + P)H. \]
Recall that \( D_T \) acts as \( N^{-1} \partial_t \) on functions. Moreover, from (2.3) one has
\[ 0 = -D_T T_{Tj} + D_i T_{ij} = \Gamma^i_{TT} T_{ij} + \Gamma^T_{Tj} T_{TT} + \partial_j P = \partial_j P, \]
i.e.
(6.2) \[ \partial_j P = 0, \]
thus \( P \) is a function only of time, \( P = P(t) \). In general, it is not a restriction to impose that the pressure and the mass satisfy the following equation of state:
\[ P = (k - 1)M, \]
for some function \( k = k(t, x) \). Particular cases of interest are given by constant values of the type:
- **Radiation Dominated**: \( k = \frac{4}{3} \);
- **Matter Dominated**: \( k = 1 \);
- **Vacuum Energy Dominated**: \( k = 0 \).

These important cases are very well known in physical literature, as they represent a standard description of the different epochs for the evolution of the Universe (see Figure 1). In the present modelization, it is possible to allow a local space-time dependence for the parameter \( k \), in a generalization of the standard picture which allows an interpolation between the constant values occurring in physical models. In particular, we have
(6.3) \[ D_T M = kHM. \]

We will use the following notation for the evolution of \( k \):
\[ D_T k = k'H \]
where \( H \neq 0 \) and we set \( k' = 0 \) whenever \( H = 0 \). From (2.4) we get
\[
| R_{\alpha\beta\gamma\delta} |^2 = | W_{\alpha\beta\gamma\delta} |^2 + 2 | R_{\alpha\beta} |^2 - \frac{1}{3} R^2 = | W_{\alpha\beta\gamma\delta} |^2 + 2 | T_{\alpha\beta} |^2 - \frac{1}{3} T^2
\]
(6.4)
\[
= | W_{\alpha\beta\gamma\delta} |^2 + \frac{5}{3} M^2 + 3 P^2 + 2 MP
\]
\[
= | W_{\alpha\beta\gamma\delta} |^2 + \frac{9k^2 - 12k + 8}{3} M^2
\]
\[
= | W_{\alpha\beta\gamma\delta} |^2 + | A_{\alpha\beta\gamma\delta} |^2,
\]
and
\[
| A_{\alpha\beta\gamma\delta} |^2 = \frac{9k^2 - 12k + 8}{3} M^2.
\]
Note also that $A_{Tijk} = 0$, since $R_{Ti} = T_{Ti} = 0$. From (6.3) we have

\begin{equation}
\frac{1}{2} D_T |A_{\alpha\beta\gamma\delta}|^2 = \frac{2k(9k^2 - 12k + 8) + 6k'(3k - 2)}{3} H M^2.
\end{equation}

On a perfect fluid, since $T_{TT} = M$, $T_{iT} = 0$, $T_{ij} = P g_{ij}$ and $T = 3P - M$, we have

\[ C_{ijT} = D_T T_{ij} - D_j T_{i} - \frac{1}{3} (D_T T_{\gamma i} - D_j T_{\gamma i}) \]
\[ = (D_T P) g_{ij} + \Gamma_{ijT} T_{TT} + \frac{1}{3} (3D_T P - D_T M) g_{ij} \]
\[ = -(M + P) h_{ij} + \frac{1}{3} (D_T M) g_{ij} . \]

From Proposition 5.3 we obtain

\begin{equation}
\frac{1}{2} D_T |W_{\alpha\beta\gamma\delta}|^2 = 16 H |W_{Tijj}|^2 - 24 h_{jl} W_{Tijj} W_{Tljl} + 4(M + P) h_{ij} W_{Tijj} ,
\end{equation}

and, if $P = (k - 1)M$, then

\begin{equation}
\frac{1}{2} D_T |W_{\alpha\beta\gamma\delta}|^2 = 16 H |W_{Tijj}|^2 - 24 h_{jl} W_{Tijj} W_{Tljl} + 4k M h_{ij} W_{Tijj} ,
\end{equation}

As a corollary, we have the following formula for the evolution of the Weyl entropy of Pure Electric Perfect Fluids:

**Proposition 6.1.** Let $(X, \gamma)$ be a globally hyperbolic perfect fluid satisfying (H1). Then, the Weyl entropy $S$ satisfies

\[ D_T S = \frac{|W| |A|^2}{R_{ij}^2} \left[ -kH - H \frac{|W|^2}{|A|^2} - 24 \frac{h_{jl} W_{Tijj} W_{Tljl}}{|W|^2} + 4k M \frac{h_{ij} W_{Tijj}}{|W|^2} \right] \]
\[ - H \frac{k'(3k - 2)M^2}{|A|^2} \sqrt{g} . \]

**Proof.** First of all, we note that if at some point $A = 0$ (i.e. $M = 0$), then $s = 1$. Since $s \leq 1$, $s$ attains a maximum and $D_T s = 0$. In this case (see (6.10) below)

\begin{equation}
D_T S = -H \sqrt{g} .
\end{equation}

On the other hand, where $A \neq 0$ using (4.2) and (4.1), we obtain

\[ D_T S = D_T (s \sqrt{g}) = \left( \frac{s}{\bar{s}} \right)^3 D_T \bar{s} \sqrt{g} + s D_T \sqrt{g} . \]

Since, from Lemma 5.1 $|A|^2 = \bar{s}$ and, from (6.4) and (6.5), we have

\[ |A|^2 = \frac{9k^2 - 12k + 8}{3} M^2 \]

and

\[ D_T |A| = \frac{k(9k^2 - 12k + 8) + 3k'(3k - 2)}{3 |A|} H M^2 . \]
Thus, from (4.3), (6.7) and Lemma 5.1 we obtain

\[ D_{T \tilde{S}} = D_T \left( \frac{|W|}{|A|} \right) = \frac{1}{|A|^2} \left( |A| D_T |W| - |W| D_T |A| \right) \]

\[ = \frac{1}{|A|^2} \left[ \frac{|A|}{|W|} \left( H |W|^2 - 24 \hat{h}_{ij} W_{TI} W_{TI} + 4kM \hat{h}_{ij} W_{TI} \right) \right. \]

\[ - H \frac{|W|}{3|A|^3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 \]

\[ = H \frac{|W|}{|A|} - 24 \hat{h}_{ij} W_{TI} W_{TI} + 4kM \hat{h}_{ij} W_{TI} \]

\[ - H \frac{|W|}{3|A|^3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2. \]

From (3.2) and the well known formula for the variation of the determinant, one has

(6.10) \[ D_T \sqrt{g} = \frac{1}{2N} (g^{ij} \partial_i g_{ij}) \sqrt{g} = -H \sqrt{g}. \]

Using Lemma 5.1, we get

\[ D_T S = \frac{|A|^3}{[R]^3} \left[ H \frac{|W|}{|A|} - 24 \hat{h}_{ij} W_{TI} W_{TI} + 4kM \hat{h}_{ij} W_{TI} \right. \]

\[ \left. \quad - H \left( \frac{|R|^2}{|A|^2} - 1 \right) - 24 \hat{h}_{ij} W_{TI} W_{TI} \right] \frac{|W|}{|A|^2} + 4kM \hat{h}_{ij} W_{TI} \]

\[ - H \frac{1}{3|A|^3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 \right] \sqrt{g} \]

\[ = \frac{|W||A|^2}{[R]^3} \left[ - H \left( \frac{|R|^2}{|A|^2} - 1 \right) - 24 \hat{h}_{ij} W_{TI} W_{TI} \right] \frac{|W|}{|A|^2} + 4kM \hat{h}_{ij} W_{TI} \]

\[ - H \frac{1}{3|A|^3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 \right] \sqrt{g}. \]

Since

\[ \frac{1}{3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 = k|A|^2 + k'(3k - 2)M^2, \]

we obtain

\[ D_T S = \frac{|W||A|^2}{[R]^3} \left[ - kH - H \left( \frac{|W|^2}{|A|^2} - 24 \hat{h}_{ij} W_{TI} W_{TI} \right) + 4kM \hat{h}_{ij} W_{TI} \]

\[ - H \frac{k'(3k - 2)M^2}{|A|^2} \right] \sqrt{g}, \]

and this concludes the proof. Note that this formula coincide with (6.9) when $A = 0$. \[ \square \]
7. Monotonicity of the Weyl Entropy in Perfect Fluid Electric Regions

In this section we will assume the spacetime \((X, \gamma)\) to be almost globally hyperbolic. In fact, we note that all the computation done in the previous sections are local, so they hold on every open subset of \(X\) where the lapse function \(N\) is strictly positive and the Weyl tensor \(W\) satisfies \((H1)\).

**Definition 7.1.** Let \((X, \gamma) = (I \times M^3, -N^2 dt^2 + g)\) be an almost globally hyperbolic spacetime, let \(U \subset M^3\) and \(I' \subset I\) be two open sets. We say that \(PF_E^k := I' \times U\) is a \(k\)-perfect fluid electric region if

1. the stress-energy tensor \(T\) is given by \((6.1)\) on \(PF_E^k\), with
   \[P = (k - 1)M, \quad k = k(t, x) \in \left[0, \frac{4}{3}\right];\]
2. the Weyl tensor \(W\) satisfies \((H1)\) on \(PF_E^k\);
3. the lapse function \(N\) is strictly positive on \(PF_E^k\).

We need also the following definition concerning the expansion and the intrinsic curvature of the space metric:

**Definition 7.2.** Let \((X, \gamma) = (I \times M^3, -N^2 dt^2 + g)\) be an almost globally hyperbolic spacetime, let \(U \subset M^3\) and \(I' \subset I\) be two empty open sets. We say that \(I' \times U\) is an \(\alpha\)-expanding region if there exists a function \(\alpha = \alpha(t, x) \in \left[0, \frac{1}{3}\right]\) such that

\[h_{ij} \leq \alpha H g_{ij} \leq 0 \quad \text{on} \quad I' \times U.\]

In particular, we will denote by \(PF_E^k, \alpha\) a \(k\)-perfect fluid electric \(\alpha\)-expanding region.

From \((3.2)\) the condition of \(\alpha\)-expansion is equivalent to

\[\partial_t g_{ij} \geq -\alpha N H g_{ij}.\]

In particular 0-expansion is equivalent to say that spatial metric is increasing in time, so the (space) region is expanding. From algebraic reasons, the case \(\alpha = \frac{1}{3}\) implies that the foliation is totally umbilical, i.e. \(h_{ij} = \frac{H}{3} g_{ij}\), or equivalently, \(\dot{h} = 0\). Note that this holds also if \(H\) is zero (minimal foliation), since the \(\alpha\)-expansion implies \(h_{ij} \leq 0\), and thus \(h = 0\).

We will assume that the fluid parameters \(k, \alpha\), satisfy the following evolution inequalities

\[(7.1) \quad 0 \leq k' \leq \frac{k(9k^2 - 12k + 8)}{3(4 - 3k)} \min \left\{ \frac{9\alpha'}{4(1 - 3\alpha)}, 1 \right\}, \quad \alpha' \geq 0,
\]

where \(D_T u =: u' H\) where \(H \neq 0\) and \(u' := 0\) where \(H = 0\). Note that, since \(H \leq 0\), the assumptions \((7.1)\) imply that \(D_T k \leq 0\) and \(D_T \alpha \leq 0\), which are very natural (see Figure 1).

As a consequence of Proposition 6.1 we can show an estimate for the modified Weyl entropy \(S_{pf}\) on a \(PF_E^k, \alpha\), defined as

\[S_{pf} := S + s_{crit} \sqrt{g} = \left( \frac{|W_{\alpha\beta\gamma\delta}|}{|R_{\alpha\beta\gamma\delta}| g} + s_{crit} \right) \sqrt{g},\]
where
\[ s_{\text{crit}} := \sqrt{1 - 3\alpha} \left( \frac{\sqrt{2}}{4} + 2k \sqrt{\frac{1 - 3\alpha}{9k^2 - 12k + 8}} \right). \]

Note that \( s_{\text{crit}} = s_{\text{crit}}(t, x) \geq 0 \) and
\[ s_{\text{crit}} = 0 \iff \alpha = \frac{1}{3}. \]

Moreover, we will show in the proof of Theorem 7.3 that the assumption (7.1) implies that \( D_T s_{\text{crit}} \geq 0 \) and thus
\[ D_T (s_{\text{crit}} \sqrt{g}) \geq 0, \]
which is very natural. The definition of \( S_{\text{pf}} \) is such that monotonicity in time is preserved only at the cost to introduce also the new contribution \( s_{\text{crit}} \), which is related in part to the geometry itself (through its dependence on the parameter \( \alpha \)) and in part on the matter field equation of state (through the parameter \( k \)). This further term vanishes only when \( \alpha = \frac{1}{3} \), i.e. in the homogeneous case. It is worthwhile mentioning that, in the standard discussions in literature, \( k \) is a constant, and also \( \alpha \) can be assumed to be constant. As a consequence, in such a situation, the definition given above amounts to shifting the ratio \( \frac{|W_{\alpha\beta\gamma\delta}|}{|R_{\alpha\beta\gamma\delta}|^{\frac{1}{2}}} \) by a constant and, moreover, the assumptions (7.1) on the parameters are automatically satisfied.

**Theorem 7.3.** On every \( k \)-perfect fluid electric \( \alpha \)-expanding region \( \mathcal{PF}_{k,\alpha} \) satisfying (7.1) the entropy \( S_{\text{pf}} \) is monotonically increasing, i.e.
\[ D_T S_{\text{pf}} \geq 0. \]
Moreover, the equality holds at some point if and only if \( D_T s_{\text{crit}} = 0 \) and either \( h = 0 \), or \( |W| = 0 \), \( \alpha = \frac{1}{3} \) and \( s_{\text{crit}} = 0 \).

**Proof.** From the \( \alpha \)-expanding assumption we have
\[ -24 \hat{h}_{ij} W_{TiTj} W_{TiTl} \geq 8(1 - 3\alpha)H|W_{TiTj}|^2 = (1 - 3\alpha)H|W|^2, \]
since \( |W|^2 = |W_{\alpha\beta\gamma\delta}|^2 = 8|W_{TiTj}|^2 \). Moreover, since \( B := h - \alpha Hg \leq 0 \), one has \( |B|^2 \leq |\text{tr}B|^2 \), i.e.
\[ |h - \alpha Hg|^2 \leq (1 - 3\alpha)^2 H^2, \]
or equivalently
\[ |h|^2 \leq (6\alpha^2 - 4\alpha + 1)H^2. \]
Recalling that \( H \leq 0 \) and \( \alpha \leq \frac{1}{3} \) we obtain the following estimate
\[ |\hat{h}| \leq -\frac{2}{3}(1 - 3\alpha)H. \]
In particular, we get
\[ |\hat{h}_{ij} W_{TiTj}| \leq -\sqrt{\frac{2}{3}}(1 - 3\alpha)H|W_{TiTj}| = -\frac{1 - 3\alpha}{2\sqrt{3}}H|W|. \]
From equation 6.8, we obtain

\[
(7.2) \quad D_T S = \frac{|W| |A|^2}{|R|^2} \left[ -kH - H \frac{|W|^2}{|A|^2} - 24 \frac{h_{lj} W_{TjTl}}{|W|^2} + 4kM \frac{h_{lj} W_{TjTl}}{|W|^2} \right. \\
\left. - H \frac{k'(3k-2)M^2}{|A|^2} \right] \sqrt{g} \\
\geq \frac{|W||A|^2}{|R|^2} \left[ k - 1 + 3\alpha + \frac{|W|^2}{|A|^2} - \frac{2k(1-3\alpha)}{\sqrt{3}} \frac{M}{|W|} \right. \\
\left. + \frac{k'(3k-2)M^2}{|A|^2} \right] (-H) \sqrt{g} \\
= \frac{|W|}{3|R|^2} \left[ (k - 1 + 3\alpha)(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 (-H) \sqrt{g} \\
+ \frac{1}{3|R|^2} \left[ |W|^3 - \frac{2k(1-3\alpha)}{\sqrt{3}} M |A|^2 \right] (-H) \sqrt{g}.
\]

Since

\[
\frac{1}{3} M^2 = \frac{1}{9k^2 - 12k + 8} |A|^2,
\]

we get

\[
D_T S = \frac{1}{|R|^2} \left[ |W|^3 - (1 - 3\alpha)|W||A|^2 - \frac{2k(1-3\alpha)}{\sqrt{9k^2 - 12k + 8}} |A|^3 \right] (-H) \sqrt{g} \\
+ \frac{M^2 |W|}{3|R|^2} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] (-H) \sqrt{g}.
\]

Using the assumption (7.1)

\[
0 \leq k' \leq \frac{k(9k^2 - 12k + 8)}{3(4 - 3k)}
\]

it is easy to see that

\[
(7.3) \quad k(9k^2 - 12k + 8) + 3k'(3k - 2) \geq k(9k^2 - 12k + 8) + 3k'(3k - 4) \geq 0
\]

obtaining

\[
(7.4) \quad D_T S \geq \frac{1}{|R|^2} \left[ |W|^3 - (1 - 3\alpha)|W||A|^2 - \frac{2k(1-3\alpha)}{\sqrt{9k^2 - 12k + 8}} |A|^3 \right] (-H) \sqrt{g},
\]

To estimate \(|W||A|^2\), when \(\alpha \neq \frac{1}{3}\), we use Young’s inequality

\[
2ab \leq \frac{1}{\theta^3} a^3 + \theta^3 b^3
\]

which holds for all nonnegative numbers \(a, b \geq 0\) and all \(\theta > 0\). Choosing

\[
\theta^3 = \frac{1 - 3\alpha}{2}
\]
and using that $|A|^3 \leq |R|^3_\gamma - |W|^3$ (since $|R|^2_\gamma = |A|^2 + |W|^2$), we get

$$D_T S \geq \frac{1}{|R|^3_\gamma} \left[ |W|^3 - (1 - 3\alpha)|W||A|^2 - \frac{2k(1 - 3\alpha)}{\sqrt{9k^2 - 12k + 8}} |A|^3 \right] (-H) \sqrt{\bar{g}}$$

$$\geq -\sqrt{1 - 3\alpha} \left( \frac{\sqrt{2}}{4} + 2k \sqrt{\frac{1 - 3\alpha}{9k^2 - 12k + 8}} \right) \frac{|A|^3}{|R|^3_\gamma} (-H) \sqrt{\bar{g}}$$

(7.5)

$$\geq -s_{\text{crit}} (-H) \sqrt{\bar{g}}$$

$$= -D_T (s_{\text{crit}} \sqrt{\bar{g}}) + D_T (s_{\text{crit}}) \sqrt{\bar{g}}.$$ We claim that the assumption on the fluid parameters (7.1) implies $D_T (s_{\text{crit}}) \geq 0$. In fact, let $A := \sqrt{1 - 3\alpha} \geq 0$. Then, since $\alpha' \geq 0$, where $A \neq 0$, we have

$$A' = -\frac{3\alpha'}{2\sqrt{1 - 3\alpha}} = -\frac{3\alpha'}{2(1 - 3\alpha)} A \leq 0.$$ Then

$$s'_{\text{crit}} = \frac{\sqrt{2}}{4} A' + \frac{4kAA'}{\sqrt{9k^2 - 12k + 8}} + 2A^2 \left( \frac{2k}{\sqrt{9k^2 - 12k + 8}} \right)'$$

$$\leq \frac{4A^2}{\sqrt{9k^2 - 12k + 8}} \left( -\frac{3k\alpha'}{1 - 3\alpha} + \frac{4k'(4 - 3k)}{9k^2 - 12k + 8} \right) \leq 0$$

if

$$0 \leq k' \leq \frac{k(9k^2 - 12k + 8)}{3(4 - 3k)} \left( \frac{9\alpha'}{4(1 - 3\alpha)} \right).$$

Thus, from (7.1) we get $D_T s_{\text{crit}} \geq 0$. Therefore, we proved that

$$D_T S_{\text{pf}} = D_T S + D_T (s_{\text{crit}} \sqrt{\bar{g}}) \geq 0.$$ We verify now the equality case. Clearly, if at some point $D_T s_{\text{crit}} = 0$ and $h = 0$, then the quantity $S_{\text{pf}} = S + s_{\text{crit}} \sqrt{\bar{g}}$ must be constant in time. Moreover, if $D_T s_{\text{crit}} = 0$, $|W| = 0$ and $\alpha = \frac{1}{3}$ (s_{\text{crit}} = 0), $D_T S_{\text{pf}} = D_T S = 0$. On the other hand, if equality holds in all the estimates of Theorem 7.3, then from equation (7.5) we get that $D_T (s_{\text{crit}}) = 0$ and either $\alpha = \frac{1}{3}$ or $H = 0$ or $|A|^2 = |R|^2_\gamma$, i.e. $|W|^2 = 0$. Since by the $\alpha$-expanding assumption the second fundamental form is nonpositive $h \leq 0$, then $H = 0$ is equivalent to $h = 0$. Thus either $\alpha = \frac{1}{3}$ or $h = 0$ or $|W| = 0$. Moreover, if $|W| = 0$ (and $H \neq 0$), then (7.2) implies $D_T S = 0$ and the assumption $D_T S_{\text{pf}} = 0$ gives also

$$0 = D_T (s_{\text{crit}}) = H s_{\text{crit}},$$ i.e. $s_{\text{crit}} = 0$ and $\alpha = \frac{1}{3}$. \hfill \Box$

**Remark 7.4.** In the special era, the critical Weyl entropy density

$$s_{\text{crit}} := \sqrt{1 - 3\alpha} \left( \frac{\sqrt{2}}{4} + 2k \sqrt{\frac{1 - 3\alpha}{9k^2 - 12k + 8}} \right)$$

is given by
• Radiation Dominated: \( k = \frac{4}{3} \)

\[
\kappa_{\text{crit}} = \sqrt{1 - 3\alpha} \left( \frac{\sqrt{2}}{4} + \frac{2\sqrt{3}}{3} \sqrt{1 - 3\alpha} \right).
\]

• Matter Dominated: \( k = 1 \)

\[
\kappa_{\text{crit}} = \sqrt{1 - 3\alpha} \left( \frac{\sqrt{2}}{4} + \frac{2}{\sqrt{3}} \sqrt{1 - 3\alpha} \right).
\]

• Vacuum Energy Dominated: \( k = 0 \)

\[
\kappa_{\text{crit}} \sim \sqrt{1 - 3\alpha} \left( \frac{\sqrt{2}}{4} \right).
\]

8. A Special Class of Pure Electric Spacetimes

Let \((X, \gamma)\) be a spacetime where the metric takes the form

\[
\gamma = -N^2(x,t)dt^2 + g_{ij}(x,t)dx^idx^j
\]

with \( N > 0 \) and

\[
g_{ij}(t,x) = e^{2\sigma(t,x)} \bar{g}_{ij}(x)
\]

for a given positive function \( \sigma : I \times M^3 \to \mathbb{R} \). In this case the foliation is totally umbilical, i.e.

\[
h_{ij} = \frac{H}{3} g_{ij}.
\]

From equations (3.4), we obtain

\[
NR_{ij} = \nabla_i \nabla_j N + \left( N \Lambda + \frac{1}{3} \dot{H} - \frac{1}{9} NH^2 \right) g_{ij}
\]

\[
0 = \nabla_j H - \nabla_k h_{jk}
\]

\[
\Delta N = -\Lambda N - \dot{H} - \frac{1}{3} NH^2.
\]

From the second equation and (8.2) we obtain

\[
0 = \nabla_j H - \nabla_k h_{jk} = \frac{2}{3} \nabla_j H,
\]

i.e. the foliation has constant (in space) mean curvature \( H \equiv H(t) \) on \( M^3 \). In particular the second fundamental form \( h_{ij} \) is a Codazzi tensor and the spacetime \((X, \gamma)\) satisfies (H1), if the stress-energy tensor is diagonal. Thus, if we consider a \( k \)-perfect fluid spacetime \((X, \gamma)\) of this form, we have that \((X, \gamma)\) is a \( k \)-perfect fluid electric \( \frac{1}{3} \)-expanding region, if we assume \( H \leq 0 \) or, equivalently, \( \partial_t \sigma \geq 0 \). In this case, since

\[
\kappa_{\text{crit}} = 0,
\]
we have $S^\text{PF} = S$ and Theorem 7.3 implies

**Proposition 8.1.** On a $k$-perfect fluid expanding spacetime satisfying (8.1) the entropy $S$ is monotonically increasing.

## 9. Perfect Fluid Magnetic Regions

In this section we will consider spacetime $(X, \gamma)$, satisfying

$$(H_2) \quad W_{T_i T_j} \equiv 0 \quad \text{on} \quad X.$$ 

As already observed, spacetimes satisfying $(H_2)$ are called *Pure Magnetic Spacetime*. Localizing this notion we define the following

**Definition 9.1.** Let $(X, \gamma) = (I \times M^3, -N^2 dt^2 + g)$ be an almost globally hyperbolic spacetime, let $U \subset M^3$ and $I' \subset I$ be two empty open sets. We say that $\mathcal{PF}_k^M := I' \times U$ is a $k$-perfect fluid magnetic region if

1. the stress-energy tensor $T$ is given by (6.1) on $\mathcal{PF}_k^M$, with $P = (k - 1)M$, $k \in [0, \frac{2}{3}]$ and

   $$0 \leq k' \leq \frac{k(9k^2 - 12k + 8)}{3(4 - 3k)},$$

   where $D_T k = k'H$ (where $H \neq 0$).

2. the Weyl tensor $W$ satisfies $(H_2)$ on $\mathcal{PF}_k^M$;

3. the lapse function $N$ is strictly positive on $\mathcal{PF}_k^M$.

Moreover, if there exists a function $\alpha = \alpha(t, x) \in [0, \frac{1}{3}]$ such that

$$h_{ij} \leq \alpha H g_{ij} \leq 0 \quad \text{on} \quad I' \times U,$$

we will say that $\mathcal{PF}_{k, \alpha}^M$ is a $k$-perfect fluid magnetic $\alpha$-expanding region.

**Lemma 9.2.** Let $(X, \gamma)$ be a globally hyperbolic spacetime satisfying $(H_2)$. Then

$$\frac{1}{2} D_T |W_{\alpha \beta \gamma \delta}|^2 = -16h_{kp} W_{Ti j k} W_{T i j p}.$$ 

**Proof.** From the second bianchi identity (2.8)

$$D_T W_{Tijk} + D_j W_{Tk i} + D_k W_{T i T j} = \frac{1}{2} (C_{Tk Tj} \gamma_{ij} + C_{TT j} \gamma_{ik} + C_{T j k} \gamma_{iT})$$

$$- \frac{1}{2} (C_{ik Tj} \gamma_{Tj} + C_{iT j} \gamma_{Tk} + C_{ij k} \gamma_{TT})$$

$$= \frac{1}{2} (C_{Tk T} g_{ij} - C_{T j T} g_{ik} + C_{ij k}).$$
Also, (2.6) and the fact that $D_i M = 0$ imply
\[
C_{TKT} := D_T T_{kT} - D_k T_{TT} - \frac{1}{3} (D_T T \gamma_{kT} - D_k T \gamma_{TT})
= -\frac{1}{3} D_k T = \frac{4 - 3k}{3} D_k M = 0
\]
and
\[
C_{ijk} := D_k T_{ij} - D_j T_{ik} - \frac{1}{3} (D_k T \gamma_{ij} - D_j T \gamma_{ik})
= D_k T_{ij} - D_j T_{ik} = 0.
\]
Thus
\[
D_T W_{Tijk} = -D_j W_{TikT} - D_k W_{TYTj} = D_j W_{TiyT} - D_k W_{TYTj}.
\]
Moreover, condition (H2) implies
\[
D_k W_{TijTj} = \partial_k W_{TijTj} - \Gamma^p_{kT} W_{piTj} - \Gamma^p_{kT} W_{Tjpj}
= -\Gamma^p_{kT} W_{Tjpj} - \Gamma^p_{kT} W_{Tjpj}
= h_{kp}(W_{Tjpj} + W_{Tjpj}).
\]
Rewriting the last equations we have proved that
\[
D_T W_{Tijk} = h_{jp}(W_{Tkip} + W_{Tijp}) - h_{kp}(W_{Tjp} + W_{Tjp}).
\]
Thus, from Lemma 5.1, we get
\[
\frac{1}{2} D_T |W_{\alpha\beta\gamma\delta}|^2 = -2 D_T |W_{Tijk}|^2 = -4 W_{Tijk} D_T W_{Tijk}
= -4 h_{jp}(W_{Tkip} + W_{Tijp}) W_{Tijk} + 4 h_{kp}(W_{Tjp} + W_{Tjp}) W_{Tijk}
= 8 h_{kp} W_{Tijk} W_{Tijp}.
\]

**Proposition 9.3.** Let $(X, \gamma)$ be a globally hyperbolic perfect fluid satisfying (H2). Then the Weyl entropy $S$ satisfies
\[
D_T S = \frac{|A|^3}{R_5^2} \left| [W]|A| \right| [W]|A| \left[ 16 \frac{h_{jp} W_{Tijk} W_{Tijp}}{|A|^3} \right]
+ H \left[ \frac{|W||R_5^2}{|A|^3} \right] \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 + H \left[ \frac{|W||R_5^2}{|A|^3} \right] \sqrt{g}
\]

**Proof.** Using (4.2) and (4.1) we obtain
\[
D_T S = D_T (s \sqrt{g}) = \left( \frac{s}{R_5} \right)^3 D_T s \sqrt{g} + s D_T \sqrt{g}.
\]
Since, from Lemma 5.1 $|A|^2 = |A|^2$ and, from (6.4) and (6.5), we have

$$|A|^2 = \frac{9k^2 - 12k + 8}{3} M^2$$

and

$$D_T|A| = \frac{k(9k^2 - 12k + 8) + 3k'(3k - 2)}{3|A|} H M^2.$$ 

Thus, from (4.3), Lemma 5.1 and Lemma 9.2 we obtain

$$D_T \bar{s} = -D_T \left( \frac{|W|}{|A|} \right) = -\frac{1}{|A|^2} \left( |A| D_T |W| - |W| D_T |A| \right)$$

$$= -\frac{1}{|A|^2} \left( |A| \left( -16h_{kjW}T_{ijk}W_{Tijp} \right) \\
- H \frac{|W|}{3|A|} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 \right)$$

$$= 16h_{ijW}T_{ijk}W_{Tijp}$$

$$+ H \frac{|W|}{3|A|^3} \left( k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2.$$ 

From (6.10), one has

$$D_T \sqrt{g} = -H \sqrt{g}.$$ 

Using Lemma 5.1, we get

$$D_T S = \frac{|A|^3}{R_{\bar{g}}^3} \left[ 16h_{ijW}T_{ijk}W_{Tijp} \right]$$

$$+ H \frac{|W|}{3|A|^3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 + H \frac{|W||R_{\bar{g}}^2|}{|A|^3} \sqrt{g}$$

and this concludes the proof.

As a corollary, we have the following monotonicity of $S$ on perfect fluid magnetic $\alpha$-expanding regions.

**Theorem 9.4.** Let $\mathcal{PF}_{k,\alpha}^M$ be a $k$-perfect fluid magnetic $\alpha$-expanding region. Then,

$$D_T S \geq 0.$$ 

Moreover, the equality holds at some point if and only if either $h = 0$ or $|W| = 0$.

**Proof.** From Proposition 9.3 we have

$$D_T S = \frac{|A|^3}{R_{\bar{g}}^3} \left[ 16h_{ijW}T_{ijk}W_{Tijp} \right]$$

$$+ H \frac{|W|}{3|A|^3} \left[ k(9k^2 - 12k + 8) + 3k'(3k - 2) \right] M^2 + H \frac{|W||R_{\bar{g}}^2|}{|A|^3} \sqrt{g}$$
Since $|W| \leq 0$, $h_{ij} \leq \alpha H g_{ij} \leq 0$, $|R| \geq |A|$, 

$$0 \leq k' \leq \frac{k(9k^2 - 12k + 8)}{3(4 - 3k)}$$

and $D_T N \geq 0$ we obtain

$$D_T S \geq \frac{|A|^3}{|R|^2} \left(1 + 4\alpha\right) H \frac{|W|}{|A|}$$

$$+ H \frac{|W|}{3|A|^3} \left(k(9k^2 - 12k + 8) + 3k'(3k - 2)\right) M^2 \sqrt{g}$$

$$\geq \frac{|A|^3}{|R|^2} \left(1 + 4\alpha\right) H \frac{|W|}{|A|} \sqrt{g} \geq 0,$$

since $\alpha \geq 0$ by assumption. The equality case follows easily. \qed

10. Regions with Maximum or Minimal Weyl Entropy

Let $I \times U$, be a $k$-perfect fluid electric region contained in an almost globally hyperbolic spacetime $(X, \gamma)$ and satisfying (7.1). From Theorem 7.3, for every $t \in I$ we have

$$D_T S_{U}^{\text{pf}} = \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U D_T S_{\text{pf}}^{\text{pf}} + D_T \left(\frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)}\right) \int_U S_{\text{pf}}^{\text{pf}} \geq D_T \left(\frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)}\right) \int_U S_{\text{pf}}^{\text{pf}}.$$

In particular, to guarantees the monotonicity of the Weyl entropy in $U$, we can assume the following

(10.1) \quad D_T \left(\frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)}\right) \geq 0.
10.1. Maximal case. We say that a time slice $U_{t_0} := \{t_0\} \times U$, $t_0 \in I$, has maximum Weyl entropy at time $t_0$, if the Weyl entropy $S_{pf}^U$ in $U$ is maximal at time $t_0 \in I$. We recall that
\[
S_{pf}^U := \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U S_{pf} = \frac{\text{Area}(\Sigma)}{\text{Vol}_g(U)} \int_U \left( \frac{|W|_\gamma}{|R|_\gamma} + s_{crit} \right) \sqrt{g},
\]
if $R \neq 0$, or
\[
S_{pf}^U = \text{Area}(\Sigma) \left( 1 + \frac{1}{\text{Vol}_g(U)} \int_U s_{crit} \sqrt{g} \right)
\]
otherwise. Since $|W|_\gamma \leq |R|_\gamma$ with equality if and only if $A = 0$ (i.e. the Ricci tensor of $\gamma$ vanishes), we get
\[
S_{pf}^U \leq \text{Area}(\Sigma) \left( 1 + \frac{1}{\text{Vol}_g(U)} \int_U s_{crit} \sqrt{g} \right) \leq \text{Area}(\Sigma) \left( 1 + \sup_U s_{crit} \right)
\]
with equality if and only if the Ricci tensor $R_{\alpha\beta}$ vanishes (the case of zero Riemann tensor $R$ is automatically included) and $s_{crit}$ is constant on $U$.

Assume now that $U_{t_0}$ has maximum Weyl entropy at time $t_0$. By the monotonicity in Theorem 7.3, all the future slices $U_t$ have maximum entropy, for all $I \ni t \geq t_0$. In this case, for all $I \ni t \geq t_0$, the Ricci tensor is zero on $U_t$, $s_{crit}$ is constant on $U_t$ and, from the Einstein equation, the stress-energy tensor $T$ is zero, i.e.
\[
R_{\alpha\beta} = 0 \quad \text{and} \quad T_{\alpha\beta} = 0 \quad \text{on} \quad U_t.
\]

Moreover, by maximality, from the equality case in the monotonicity Theorem 7.3, we obtain that, on $U_t$, one has $D_T s_{crit} = 0$ (and $s_{crit} = \sup_U s_{crit}$) and either $h = 0$ or $|W| = 0$ and $\alpha = \frac{1}{3}$ (and $s_{crit} = 0$). In the second case, since it is Ricci flat, the region is flat, i.e.
locally isometric to a quotient of the Minkowski Space. In the first case, \( h = 0 \), the space metric \( g \) does not depend on \( t \) and from equations (3.4), the region \( U_t \) is static. More precisely, the triple \((U, g, N)\) satisfies the following system

\[
\begin{aligned}
NR_{ij} &= \nabla_i \nabla_j N \\
\Delta N &= 0
\end{aligned}
\quad \text{on } U.
\]

In particular \((U, g)\) has zero scalar curvature \( R = 0 \). Note that we can ensure that the lapse function \( N \), which a priori could depend on time, is in fact equal to \( N(t_0, x) \) on \( U_t \), for every \( I \ni t \geq t_0 \). This follows immediately form the local uniqueness for the Cauchy development satisfying the constraint equations (which in this case is simply \( R = 0 \)) on the slice \( \{t_0\} \times U \).

In both cases, the solution is a static vacuum spacetime in the whole \([t_0, +\infty) \cap I \times U\) (see Figure 2 and Figure 3) and the Weyl entropy \( S_{U}^{\text{pf}} \) is constant in time and equal to

\[
S_{U}^{\text{pf}} = \text{Area}(\Sigma) \left(1 + \sup_{U} s_{\text{crit}}\right).
\]

Suppose now that \( t \in [t_0, T) \) for some maximal time \( T \in \mathbb{R}^+ \). Then, either \( T = +\infty \) (and in this case the lapse function must be strictly positive everywhere) or \( T < +\infty \). In this second case, assume that there exists a point \( x \in \bar{U}_t \) such that \( \lim_{t \to T} N(t, x) = 0 \). Since \( N(t, x) = N(t_0, x) \), this implies that \( t_0 \) actually has to be the maximal time of existence \( T \).

Since \( N(t_0, -) > 0 \) in \( U \), the point \( x \in \Sigma = \partial U \). By Hopf lemma, since the lapse function \( N \) is nonnegative on \( U_t^c \), the function \( N \) has to be identically zero on the boundary \( \Sigma \), i.e.

\[
N(x) = 0 \quad \text{for all } x \in \Sigma.
\]

This means that, either the maximum entropy region is the whole cylinder \([t_0, +\infty) \times U\) or, \( T < \infty \) and either \( N > 0 \) or \( t_0 = T \) and the lapse function \( N \) vanishes on the surface \( \Sigma \). In this case \( \Sigma \) is the so called a event horizon and we have the maximal Weyl entropy satisfies

\[
S_{U}^{\text{pf}} = \text{Area}(\Sigma) \left(1 + \sup_{U} s_{\text{crit}}\right) = S_{\text{GH}} \left(1 + \sup_{U} s_{\text{crit}}\right)
\]

where \( S_{\text{GH}} \) is governed by the same area law as the black hole entropy but is associated with a cosmological event horizon, and was introduced by Gibbons and Hawking [12]. It is still a maximal entropy in itself, and is associated with a sort of equilibrium state of the geometry, i.e. with a static solution.

Reasoning as above, the same things for the Weyl entropy \( S_U \) happen in a maximal \( k \)-perfect fluid magnetic region, as a consequence of Theorem 9.4. We note that a static region cannot occur, since in case the Weyl tensor would be pure electric. Therefore, maximal Weyl entropy regions must be flat (vacuum).

10.2. Minimal case. We deal now with the minimal case. We say that a time slice \( U_{t_0} = \{t_0\} \times U, t_0 \in I \), has minimal Weyl entropy at time \( t_0 \), if the Weyl entropy \( S_{U}^{\text{pf}} \) in \( U \) is minimal.
at time $t_0 \in I$. Since $S^\text{pf}_U \geq 0$, the minimal value is zero, from $|W|_\gamma \geq 0$ and $s_{\text{crit}} \geq 0$, we obtain that at
\begin{equation}
W \equiv 0, \quad s_{\text{crit}} \equiv 0 \quad \text{on } U_{t_0} \iff W \equiv 0, \quad \alpha \equiv \frac{1}{3} \quad \text{on } U_{t_0}
\end{equation}
Assume now that $U_{t_0}$ has minimal Weyl entropy at time $t_0$. By the monotonicity in Theorem 7.3, all the past slices $U_t$, have minimal entropy, for all $I \ni t \leq t_0$. In this case, for all $I \ni t \leq t_0$, the Weyl tensor vanishes and $\alpha = \frac{1}{3}$ on $U_t$. We claim that on the spacetime cylinder $([0, t_0] \cap I) \times U$ the metric must be of Friedmann-Lemaître-Robertson-Walker type, i.e. the spacetime metric has the form
\[ \gamma = -N(t)^2 dt^2 + a(t)^2 g^K_{ij}(x) dx^i dx^j, \]
where $N = N(t)$ is the original lapse function which now depends only on time, $a = a(t)$ is a positive function depending only on time and $g^K$ is a Riemannian metric of constant sectional curvature $K$ on $U$. It is a FLRW metric up to rescaling the time appropriately with the lapse function. In fact, from (10.2) and the definitions of $\alpha$-expansion (7.2) and (9.1), we get that the slices must be umbilical
\[ h_{ij} = \frac{1}{3}H g_{ij}. \]
In particular, from (3.4), we obtain that
\[ 0 = \nabla_j H - \nabla_k h_{jk} = \frac{2}{3} \nabla_j H, \]
i.e. the foliation has constant (in space) mean curvature $H \equiv H(t)$ on $U$. Thus, from umbilicity and (3.2), we get
\begin{equation}
\partial_t h_{ij} = \frac{1}{3}(\partial_t H) g_{ij} + \frac{1}{3}H \partial g_{ij} = \frac{1}{9}(\partial_t H - 2NH^2) g_{ij}.
\end{equation}
Since $T_{TT} = M$, $T_{ij} = P g_{ij} = (k-1)M g_{ij}$ and $W \equiv 0$, from (3.9) and (10.3), we obtain
\[ 0 = NW_{TT} = -N \frac{2-k}{2} M g_{ij} + N \frac{4-3k}{3} M g_{ij} + \frac{1}{9}(\partial_t H - 2NH^2) g_{ij} + \frac{1}{9}NH^2 g_{ij} + \nabla_i \nabla_j N, \]
and thus
\[ \nabla_i \nabla_j N = \varphi(t, x) g_{ij} \]
for some function $\varphi$. Using this equation and (10.3) in (3.4), we obtain
\[ N \frac{2-k}{2} M g_{ij} = N R_{ij} - \frac{1}{9}(\partial_t H - 2NH^2) g_{ij} + \frac{1}{3}NH^2 g_{ij} - \frac{2}{9}NH^2 g_{ij} - \varphi g_{ij} \]
and therefore, the Ricci tensor of the metric $g$ satisfies in $U$
\[ R_{ij} = \psi(t, x) g_{ij} \]
for some function $\psi$. By Bianchi identity, the function $\psi$ must be constant in space, $\psi = \psi(t)$, and the metric $g$ is Einstein. Since $U \subset M^3$ is three-dimensional, $(U, g)$ must have constant (in space) sectional curvature. Thus we have proved that
\[ g_{ij}(t, x) = a(t)^2 g^K_{ij}(x) \]
where $g^K$ is a Riemannian metric of constant sectional curvature $K$ on $U$. Thus, the spacetime metric $\gamma$ takes the form

$$
\gamma = -N(t,x)^2 dt^2 + a(t)^2 g^K_{ij}(x) dx^i dx^j.
$$

It remains to show that the lapse function is constant in space, $N = N(t)$. By the conformal flatness of $\gamma$, $W \equiv 0$, we have that the conformal metric

$$
\tilde{\gamma} = N(t,x)^{-2} \gamma = -dt^2 + \left[\frac{a(t)}{N(t,x)}\right]^2 g^K_{ij}(x) dx^i dx^j.
$$

is conformally flat. From well known results in Riemannian (or, more in general, pseudo-Riemannian) Geometry, it is possible to show (by direct local computation) that the only possibility for $\tilde{\gamma}$ to be conformally flat, is that the warping function $a/N$ depends only on $t$, i.e. the lapse function $N$ depends only on $t$. This concludes the proof of the claim.

To conclude, we have shown that if a time slice $U_t_0 = \{t_0\} \times U$ has minimal (zero) Weyl entropy, then the spacetime cylinder $([0,t_0] \cap I) \times U, \gamma$ is a FLRW spacetime. Again, by uniqueness for the Cauchy development, this must happen on the entire cylinder $I \times U$, if the FLRW solution exists until the final time $T \in I$.

As this situation is unphysical, we can avoid it by assuming the condition $D_T \alpha(0) < 0$ at some point $x \in U$, which, under our hypotheses, would imply $\alpha(t,x) < \frac{1}{3}$ for all $t \in I$. This hypothesis is quite mild, as it correspond to assuming that the Universe is non-homogeneous for $t > 0$.
