ABSTRACT The nematode Caenorhabditis briggsae is an excellent model organism for the comparative
analysis of gene function and developmental mechanisms. To study the evolutionary conservation and
divergence of genetic pathways mediating vulva formation, we screened for mutations in C. briggsae that
cause the egg-laying defective (Egl) phenotype. Here, we report the characterization of 13 genes, including
three that are orthologs of Caenorhabditis elegans unc-84 (SUN domain), lin-39 (Dfd/Scr-related homeo-
box), and lin-11 (LIM homeobox). Based on the morphology and cell fate changes, the mutants were placed
into four different categories. Class 1 animals have normal-looking vulva and vulva-uterine connections,
indicating defects in other components of the egg-laying system. Class 2 animals frequently lack some or all
of the vulval precursor cells (VPCs) due to defects in the migration of P-cell nuclei into the ventral hypo-
dermal region. Class 3 animals show inappropriate fusion of VPCs to the hypodermal syncytium, leading to
a reduced number of vulval progeny. Finally, class 4 animals exhibit abnormal vulval invagination and
morphology. Interestingly, we did not find mutations that affect VPC induction and fates. Our work is the
first study involving the characterization of genes in C. briggsae vulva formation, and it offers a basis for
future investigations of these genes in C. elegans.

Invertebrate model organisms such as the nematode Caenorhabditis elegans are excellent model organisms for investigating the genetic
basis of development. Studies in C. elegans have provided insights into the cellular and molecular basis of organ formation and have revealed
similarities and differences in the formation of homologous structures in metazoans.

Nematodes are an attractive system for studying the evolution of developmental mechanisms because they offer many useful features,
including rapid development, transparency, and large brood size.

Comparative studies in nematodes have revealed similarities and differences in the vulva, the egg-laying organ. For example, the vulval
precursor cell (VPC) equivalence group in Oschieus tipulae and Pristionchus pacificus is smaller than that of C. elegans (Sommer 2005; Sternberg 2005).
Furthermore, in Pristionchus, the mechanism of restricting vulval precursor competence is different. Although cell
fusion limits precursor competence in C. elegans, programmed cell death controls this process in P. pacificus (Sommer 2005). In addition
to these two species, vulval morphology has been examined in a large number of other nematodes, and differences have been found in the
number of vulval progeny and the placement of the vulva (Felix et al. 2000; Felix and Sternberg 1997; Sommer et al. 1994; Sommer and
Sternberg 1996). More recently, Kiontke et al. (Kiontke et al. 2007) examined 51 rhabditid species and identified variations in different
steps of vulva development. In the Caenorhabditis genus, Caenorhabditis briggsae is an excellent model for comparative and evolutionary
studies (Gupta et al. 2007). Sequence analyses of C. elegans and C. briggsae have suggested a divergence of approximately 30 million
years (Cutter 2008). Morphologically, C. briggsae is almost identical to C. elegans; however, sequence comparison has revealed that almost one-
third of all predicted genes in its genome are highly divergent (Gupta
and Sternberg 2003; Stein et al. 2003). Both organisms offer powerful tools for dissecting gene function, including rapid development, invariant cell lineages, fully sequenced genomes, and amenability to both genetic and molecular manipulation (Antoshechkin and Sternberg 2007; Gupta et al. 2007; Hillier et al. 2007; Stein et al. 2003; Zhao et al. 2010). The hermaphroditic mode of reproduction of these species is another advantage because it allows for the maintenance of mutations that affect mating and egg laying. Organisms with divergent genomes but overall morphological similarity may offer intriguing examples of how networks of genes can be regulated differently while yielding the same ultimate structure.

Comparative studies of C. elegans and C. briggsae have revealed that alterations in developmental mechanisms do not always affect morphology. For example, the expression pattern of lin-39, an important Hox family member (Dfd/Scr-related) that regulates VPC competence, differs between the two species, yet VPC induction and cell fates are conserved (Penigault and Felix 2011a). The role of the Wnt pathway effector pop-1 (TCF/LEF family) in C. briggsae endomesoderm specification represents yet another case of altered gene function with no obvious change in embryonic cell divisions or tissue morphology (Lin et al. 2009). In another case, knockdown of the lin-12/Notch receptor family member glp-1 causes a multivulva (Muv) phenotype in C. briggsae but not in C. elegans (Rudel and Kimble 2001). Thus, glp-1 appears to have acquired a new function in negative regulation of VPC fate specification in C. briggsae. Such alterations in gene function without apparent changes in homologous characters were described originally as developmental system drift (DSD) (True and Haag 2001).

The egg-laying system of C. briggsae is well suited for comparative analysis of gene function in organ formation, and it is helpful in elucidating DSD. Morphologically, the system is identical to C. elegans and follows a similar sequence of developmental events. Several of the vulval characters, such as cell number, position in the midbody region, and cell fusions are shared between these two species. However, some differences also have been noted. For example, the division frequency of the P3.p vulval precursor is higher in C. elegans than in C. briggsae (Delattre and Felix 2001). Other differences that have been found include the role of anchor cell (AC) in the vulval induction process, uterine seam (ute) cell morphology, brood size, sheath-contraction rate, and reproductive efficiency (Delattre and Felix 2001; Felix 2007; Gupta and Sternberg 2003; Miller et al. 2004). Subtle variations in VPC responses to inductive and lateral signaling cascades also have been reported (Felix 2007; Hoyos et al. 2011). Thus, there are some distinct differences in the mechanisms of vulva formation and egg-laying between C. elegans and C. briggsae.

In C. elegans, the egg-laying system is composed of five different cell types, namely, the vulva, somatic gonad (uterus), vulva and uterine muscles, and neurons (Li and Chalfie 1990). The vulva is connected to the uterus via a multinucleated ute cell (Newman and Sternberg 1996) and serves as a passageway for egg laying. Defects in any of the egg-laying components can cause eggs to accumulate in the uterus, resulting in an Egg-laying defective (Egl) phenotype. The C. elegans vulva is formed by the descendants of three of six equipotent VPCs. The VPCs are the posterior daughters of P cells. At hatching, the L1 larva contains six bilaterally symmetrical pairs of P cells in the ventrolateral region. By the mid-L1 stage, P cells migrate into the ventral cord region and become arranged in a single row (numbered P1 to P12) (Sulston 1976 and Sulston and White 1980). This process involves an orchestrated series of events initiated by the directed migration of P-cell nuclei. As a nucleus migrates, it drags the rest of the cell body along with it. Several genes have been identified that affect P-cell nuclear migration, including UNC-83 (KASH domain) and UNC-84 [SUN domain (Starr 2011)]. These two proteins are localized to the outer and inner nuclear membranes, respectively (McGee et al. 2006), and they bridge the nuclear envelope and facilitate nuclear migration by transferring forces from the cytoskeleton to the nuclear lamina.

Soon after arriving at the ventral cord region, all 12 P cells divide once along the anteroposterior axis. Of the posterior daughters, five (P1.p, P2.p, P9-11.p) fuse with the hyp7 syncytium during the L1 stage. P12.p produces two daughters: P12.pp, which undergoes programmed cell death, and P12.pa, which adopts a unique epidermal fate, hyp10. The remaining 6 Pn.p cells (n = 3 to 8, VPCs) remain unfused in L1 due to the action of the Hox gene lin-39. These VPCs respond to later developmental cues. P3.p loses competence in the L2 stage in roughly half of animals and fuses with hyp7 (termed ‘F’ fate).

Although all six VPCs are equally capable of giving rise to vulval tissue, only P5.p, P6.p, and P7.p do so in wild-type animals. This is due to the action of three evolutionarily conserved signal transduction pathways mediated by LET-60/Ras-MPK-1/MAPK (inductive signaling), LIN-12/Notch (lateral signaling), and Wnt-BAR-1/β-catenin (Eisenmann 2005; Greenwald 2005; Sternberg 2005). In the L3 stage, the gonadal AC secretes the ligand LIN-3/EGF that binds to LET-23/EGFR on VPCs, leading to the activation of LET-60/Ras signaling in P6.p and to a lesser extent in P5.p and P7.p. Induced P6.p serves as a source of lateral signal that activates the LIN-12/Notch receptor in P5.p and P7.p. The inductive and lateral signaling together specify 1° (P6.p) and 2° (P5.p and P7.p) cell fates. In addition, Wnt signaling also participates in this process (Gleason et al. 2006; Seetharaman et al. 2010). The remaining uninduced VPCs fuse with hyp7 after one cell division (termed 3° fate).

Forward genetics is an elegant method by which to study vulva formation in C. briggsae and to compare its developmental mechanisms with C. elegans. We have isolated mutations in C. briggsae AF16 by using the Egl phenotype as an assay. In this study, we describe 19 mutants, 17 of which fall into four phenotypic categories and represent 13 different genes. Class 1 mutants exhibit the Egl phenotype with normal vulval cells and morphology. Class 2 mutants lack some or all of the Pn.p cells in the ventral hypodermal region, suggesting that these genes play important roles in maintaining the correct number of P cells in the ventral hypodermal region. Class 3 mutants have a normal number of VPCs, but some precursor cells fail to be induced. Class 4 mutants affect the differentiation of vulval progeny and lead to abnormal vulval morphology in L4 larvae and a protruding vulva (Pvl) phenotype in adults. We also provide evidence that three of the genes recovered in our screen, Cbr-lin(sy5506) (class 2), Cbr-lin(bh20) (class 3), and Cbr-lin(sy5336) (class 4), are orthologs of C. elegans unc-84, lin-39, and lin-11, respectively.

The mutants and phenotypic classes described here serve as the nucleus of our effort to investigate the genes involved in vulva formation in C. briggsae. In addition, they provide a tool for identifying interacting genes through enhancer and suppressor screens. These findings will facilitate the comparison of cellular and molecular processes between C. briggsae and C. elegans in studying conservation and divergence in developmental mechanisms.

**MATERIALS AND METHODS**

**Strains and culture conditions**

Wild-type C. briggsae AF16 was used as a reference strain in all experiments. Strains were maintained at 20° using culture methods described for C. elegans (Brenner 1974; Wood 1988). To obtain synchronized
animals, gravid hermaphrodites were bleached. The bleach solution was prepared using sodium hypochlorite (commercial bleach) and 4 N sodium hydroxide (NaOH) at a ratio of 3:2. For 2 volumes of worms washed with M9 buffer, 1 volume of the bleach solution was added. The solution was vortexed and left to stand for 3 min at room temperature. After three consecutive washes with M9 solution, a pellet with 1 mL of remaining M9 buffer was transferred to an Eppendorf tube and placed in a shaker. Twenty-four hours later, the F1 worms were plated onto a new NG plate.

The strains used in this study are listed below (linkage groups of mapping markers are also mentioned; see www.brggbsae.org for details). The egl(bh6) strain [allelic to egl(bh2)] was lost during the course of this study. The ‘Cbr’ prefix denotes the C. briggsae orthologs of known C. elegans genes.

Mapping mutants: dpy(sy5148) II, dpy(sy5022) III, sma(sy5330) I, unc(sy1270) IV, unc(sa997) V, unc(sy3077) X.

Egl and Vul mutants: egl(bh2), egl(bh6), egl(bh21), egl(sy5395), lin(bh7), lin(bh13), lin(bh14), lin(bh20), lin(bh23), lin(bh25), lin(bh26), lin(sy5197), lin(sy5212), lin(sy5336), lin(sy5368), lin(sy5425), lin(sy5426), unc(sy5505), unc(sy5506).

Transgenic strains: bhEx31[pRH51(hc-lin-3) + myo-2::GFP], bhEx78[F50(lin-11) + myo-2::GFP], bhEx117[unc-7:GFP + myo-2::GFP], bhEx123[C07H6 + myo-2::GFP], bhEx124[C07H6 + myo-2::GFP], bhEx132[F44F12 + myo-2::GFP], bhEx133[F44F12 + myo-2::GFP], bhEx139[pSL38(unc-84) + myo-2::GFP], bhEx141[pSL38(unc-84) + myo-2::GFP], bhEx142[pSL38(unc-84) + myo-2::GFP], bhEx148[pGF50(lin-11) + myo-2::GFP], bhEx152[pSL38(unc-84) + myo-2::GFP], mfs15[Cbr-egl-17::GFP + myo-2::GFP], mfs18[Cbr-zmp-1::GFP + myo-2::GFP].

mfs15 and mfs18 animals carry a gfp reporter driven by the vulva-specific enhancers of Cbr-egl-17 (748 bp) and Cbr-zmp-1 (755 bp), respectively (Kirouac and Sternberg 2003). bhEx117 is a transgenic HK104 line that was used in polymorphism-based mapping experiments (see below).

Mutagenesis

AF16 animals were mutagenized by soaking in 25 mM ethyl methane sulfonate (EMS) and screening for Egl and Pvl mutants in the F2 generation. To prevent worms from burrowing into the agar, we used 9-cm NG-Agarose plates (1 L of media containing 3 g of sodium chloride, 2.5 g of bacteriological peptone, and 17 g of agarose; the other components were the same as nematode growth medium). Mutagenized worms were individually transferred onto plates, and the F2 progeny were screened for Egl worms. Such animals formed the characteristic “bag of worms” phenotype as a result of the progeny hatchling inside the uterus and devouring the mother (Horvitz and Sulston 1980).

From four independent F2 screens (in the range of 100,000-125,000 haploid genome sets in total), we recovered 39 independent Egl clones that bred true. An additional 34 Egl clones could not be propagated because they were either sterile or gave rise to dead progeny. Apart from animals with the Egl phenotype, we also recovered dumpy and uncoordinated mutants. One of these, twitcher, was isolated from at least three independent plates (B. P. Gupta, unpublished results). In C. elegans and C. briggsae, the twitcher phenotype is associated with unc-22, a gene with more than 20 kb of open reading frame that is readily mutated in EMS screens (Benian et al. 1993). All three twitcher mutations are recessive and have been found to be allelic (data not shown), which suggests that our screens were capable of recovering viable recessive mutations with a visible phenotype.

This study focuses on a collection of 19 mutations that reside in 13 genes (see Results). Compared with the original C. elegans Egl screen (Trent et al. 1983), the number of Egl mutants in our case is considerably lower. It is unclear whether this is due to differences in the population of screened worms, as Trent et al. did not provide an estimate of the number of worms that were screened. Based on the mapping and complementation experiments, 70% of C. briggsae genes (9 of 13) are represented by single mutations (see Results). Although this result is indicative of the screen being unsaturated, the proportion of genes defined by a single allele in our case is very similar to that of Trent et al. (Trent et al. 1983). Furthermore, it is worth pointing out that additional alleles of the existing C. briggsae genes may be present among the remaining 20 mutations that have yet to be characterized. This analysis is the focus of our current study.

Similar to C. elegans (Ferguson and Horvitz 1985; Trent et al. 1983), not all C. briggsae mutants described here affect vulva formation, indicating that defects in other egg-laying components (such as neurons and muscles) can also lead to the Egl phenotype. Each mutant was backcrossed at least three times before we performed genetic experiments. All alleles were recessive and caused no obvious maternal effect phenotype.

Microscope, cell ablations, and VPC fates

Worms were mounted on agar pads as described previously (Wood 1988) and examined under Nomarski optics using Zeiss Axioimager D1 and Nikon Eclipse 80i microscopes. Sodium azide (1 M) was used as an anesthetic. To examine vulval lineages, L3 and L4 stage animals were mounted without any anesthetic, and coverslip edges were sealed with Vaseline to prevent dehydration. For GFP reporter-expressing strains, epifluorescence was visualized with a Zeiss Axiosplan microscope equipped with the GFP filter HQ485LP (Chroma Technology), a power source (Optiquip 1500) and a 200 W OSRAM Mercury bulb. Cell ablation experiments were performed as described (Avery and Horvitz 1987).

VPC fates were examined in L3 and L4 stage animals under a Nomarski microscope. If a VPC fused with hyp7 as a single cell without dividing, it was assigned an ‘F’ (Fused) fate. If the VPC divided once and its daughters (Pn.pxx, where x denotes both anterior and posterior cells) fused with hyp7, it was assigned a 3° (ternary) fate. If the VPC was induced to give rise to more than 4 vulval progeny (Pn.pxxx cells), it was considered fully induced and assigned an ‘T’ (induced) fate [includes 1° and 2° fates as described previously (Sternberg and Horvitz 1986)]. Vulval induction score was calculated as described previously (Gupta et al. 2006). In sy5353 and sy5353; bh20 mutants some of the Pn.p appeared small and morphologically similar to P12.p (Seetharaman et al. 2010). These were termed as “small” cells.

To determine inter-VPC distances in lin-39 mutants, animals were bleach synchronized. Distances among the 5 VPC pairs (P3.p-P4.p, P4.p-P5.p, P5.p-P6.p, P6.p-P7.p, P7.p-P8.p) were measured in mid-to-late L2 stage animals using Nikon NIS Elements software.

Micropharmacological assays

Serotonin and fluoroxetine were used to analyze the pharmacological response of some of the Egl mutants. Serotonin (35 mM) and fluoroxetine (1 mg/mL) solutions were freshly prepared in M9 buffer. The assay was performed in 96-well microtiter dishes using 50 μL of drug in individual wells. As a control, the same volume of M9 buffer was placed in adjacent wells. L4 animals were picked a day before the assay and allowed to grow for 18-24 hr before placing them individually into drug and M9 containing wells. After incubating worms for 1 hr at
..., room temperature, the number of eggs laid by each worm was counted. Assays were repeated at least three times.

**Heat shock protocol**

L1 animals of the *bhEx31* strain were transferred to standard NG agar plates containing *Escherichia coli* OP50 bacteria and grown for a desired period of time. Plates were sealed with Parafilm (American National Can) and heat shocked in a water bath. We tested various heat shock conditions by fixing the temperature at 37°C and varying the duration of the exposure. Two different types of pulses, i.e., a single long pulse (between 0:30 hr and 1:30 hr) and multiple short pulses (either consisting of four 30-min pulses each separated by 1-hr rest period or two 1-hr pulses separated by 1h, i.e., 1-hr rest period), were tested. Animals were heat shocked at different time points after transferring L1 worms on bacteria-containing plates. After the initial trials, we chose 37°C for 1 hr for all subsequent experiments. After heat shock treatment, animals were shifted back to 20°C. Vulval induction and morphology were examined at stage L4.

**Egl penetration assay**

L4 animals were placed individually into six-well nematode growth medium–agar plates and observed over a 3-day period. Egl phenotype was classified as Egl (no laid eggs, “bag of worms” appearance), semi-Egl (few eggs initially but eventually formed “bag of worms”), and Non-Egl (no defect, phenotypically wild type).

**Complementation tests**

Complementation tests between two vulval mutants (*m1* and *m2*) were performed by crossing *m1/+* heterozygote males (obtained by crossing *m1/m1* hermaphrodites to *myo-2::gfp carrying mfIs5 or mfIs8 males) to *m2/m2* hermaphrodites. The presence of the *gfp* transgene allowed us to identify cross progeny. In the F2 generation, vulval phenotype in L4 worms was scored under Nomarski optics. Complementation tests were carried out for mutations belonging to the same phenotypic categories. Table 1 lists all combinations that were tested and the results.

**Phenotypic marker-based genetic mapping**

We tested the linkage of *lin-11*(*sy5336*) with several phenotypic markers that were assigned to various chromosomes. The website www.briggsae.org shows a larger list of mapping experiments involving these markers. The *sy5336* mutation was linked to *sma*(*sy5330*) (Table 2). Together these two genes define a single linkage group that was assigned chromosome 1 based on *sy5336* molecular identity and synteny of the *lin-11* genomic region (http://www.wormbase.org). The unc(*sy5506*) mutation was linked to chromosome X based on the Unc phenotype of F1 males derived from a cross of *sy5506* hermaphrodites to AF16 males.

**Insertion-deletion (indel) and snip-SNP-based genetic mapping**

All mutations except *lin(bh14)* and *Cbr-lin-11* alleles were mapped to chromosomes by bulk segregant analysis (BSA) using Indels and snip-SNPs (Table 3, Supporting Information, Figure S1). The cross scheme was as follows. Hermaphrodites of a given mutant strain were crossed with either normal or GFP fluorescing (*bhEx117*) HK104 males. F1 cross progeny were picked and cloned. In the next generation (F2), phenotypically mutant and wild-type animals (20 each) were picked separately and processed to obtain genomic DNA. Genomic DNA was prepared by placing worms into 5 to 10 μL of lysis buffer (containing Proteinase K). The solution was incubated at 60°C for 1 hr followed by heat inactivation of Proteinase K at 95°C. This crude genomic DNA prep was frozen at −20°C and used as a template in polymerase chain reaction experiments. The detailed indel mapping protocol and primers have been published previously (Koboldt et al. 2010). We reported earlier the single recombinant analysis of *lin*(*sy5506*) using the indel *bhP26*. The distance between the two loci was determined to be 10% (Koboldt et al. 2010).

**SNP chip–based genetic mapping**

In addition to the aforementioned polymorphism-based BSA mapping, we used a microarray chip mapping approach to localize the mutations on chromosomes (Table 3). For this, a 12x oligo microarray chip containing approximately 4500 SNPs was designed using methods similar to those for *C. elegans* (Filbotte et al. 2009). An earlier version of the *C. briggsae* chip contained almost 9700 SNPs and was successfully used to map mutations (Zhao et al. 2010). *C. briggsae* Egl animals were mated with HK104 males, and F1 heterozygotes were cloned. In the F2 generation, 100 mutant worms were picked and allowed to grow on 10 6-cm Petri plates close to starvation. The worms were washed off with M9 buffer. Genomic DNA was extracted using the Qiagen Blood and Tissue DNeasy kit (cat. no. 69504). DNA hybridization, measurement of fluorescence intensity and ratio analysis were performed as described previously (Filbotte et al. 2009; Maydan et al. 2007). Based on the mapping signal intensity and the arc of the signal (Figure S2), the approximate chromosomal locations of mutations were determined (Zhao et al. 2010). In some cases, such as *sy5505*, arc pattern was not obvious, rendering the analysis less reliable. Overall, the SNP-chip data agreed with seven of the indel and snip-SNP BSA mapping results (Table 3). Independent verification of these results by phenotypic-marker-based classical mapping has not been performed.

| Table 1 Results of complementation experiments |
|-----------------------------------------------|
| m1/+ | m2/m2 | Animals Showing Phenotype | Phenotype Scored |
| bh2/+ | bh6 | 39% (n = 28) | Egl |
| bh7/+ | bh14 | 0% (n = 60) | Vul |
| bh7/+ | bh20 | 0% (n = 23) | Vul |
| bh14/+ | bh20 | 0% (n = 31) | Vul |
| sy5197/+ | bh13 | 62% (n = 8) | Sma, vulval invagination abnormal |
| bh13/+ | bh25 | 0% (n = 30) | Egl, Sma, vulval invagination abnormal |
| sy5336/+ | sy5368 | 58% (n = 12) | Egl, vulval invagination abnormal |

| Table 2 Linkage mapping of *Cbr-lin-11* using phenotypic markers |
|-----------------------------------------------|
| Marker | LG | Data |
| sma(*sy5330*) | I | 2/39 Sma were Egl |
| dpy(*sy5148*) | II | 19/29 Egl segregated Dpy |

| unc(*sy997*) | V | 24/32 Unc segregated Egl |
| unc(*sy5077*) | X | 15/32 Unc segregated Egl |
Molecular biology and transgenics

Transgenic worms were generated by injecting DNA into the syncytial gonad of adult hermaphrodites using myo-2::GFP (pPD118.33) as a transformation marker (S. Q. Xu, B. Kelly, B. Harfe, M. Montgomery, J. Ahnn, S. Getz, and A. Fire, personal communication). The micro-injection technique was described previously (Mello et al. 1991).

The pSL38 plasmid, which contained a C. elegans unc-84 rescuing fragment (McGee et al. 2006), was injected at 4 ng/μL in unc(sy5505) and unc(sy5506) animals. Stable lines (sy5505: bhEx141 and bhEx142, sy5506: bhEx139 and bhEx152) were analyzed for the rescue of Unc, P cell migration, and Egl phenotypes.

The hclin-3 transgenic animals, bhEx31, carry the pRH51 plasmid [50 ng/μL (Katz et al. 1995)], pRH51 contains the EGF domain of lin-3 along with a synthetic signal peptide. The expression of lin-3 is under the control of the hsp16-41 promoter (pPD49.83).

For the rescue of Cbr-lin-39 mutants, C. elegans cosmid C07H6 and F44F12, containing the entire lin-39 genomic region, were injected into bh20 animals. Two stable lines were obtained for each cosmid (bhEx123 and bhEx124 with C07H6 at 20 ng/μL; bhEx132 and bhEx134 with F44F12 at 0.7 ng/μL). VPC induction and Egl phenotypes were analyzed in transgenic animals. A greater proportion of F44F12 stable lines showed rescue of the Egl phenotype compared to C07H6. Therefore, we focused on bhEx132 and bhEx134 transgenic animals for all subsequent analyses.

Cbr-lin-11 cDNA was amplified using the ProtoScript first strand kit (NEB, #E6500S). The primers cb-lin-11-up-1 and cb-lin-11-down-2 (Table S1) were used. Whole RNA was prepared from the mixed stage animals using a previously described TRIZOL method (Burdine and Stern 1996). The C. elegans lin-11-rescuing plasmid pGF50 (Freyd 1991) was injected at 20 ng/μL. pGF50 contains a 19-kb subclone of cosmid ZK273 that was previously shown to rescue C. elegans lin-11 mutants (Freyd 1991). Two stable lines (bhEx78 and bhEx148) were generated for pGF50 (20 ng/μL), both of which rescued Egl and vulval invagination defects in sy5336 animals.

Sequencing

All primer sequences are listed in Table S1. The exons of Cbr-unc-84 were amplified using primer pairs GL793/GL795, GL800/GL801, GL806/GL812, and GL809/GL810. To sequence the intermediate regions, primers GL802, GL807, and GL808 were used. A 403-bp deletion between exons 6 and 7 (genomic location +5006 and +5408) was identified that introduces an in-frame stop codon downstream of the deleted region.

Cbr-lin-39 exons were amplified from bh20 and bh23 alleles using primer pairs GL380/GL381, GL382/GL383, GL384/GL385, GL389/GL390, and GL391/GL392. The bh23 mutation contains a 364-bp deletion overlapping with the 5′ region of the Cbr-lin-39 coding sequence. The deletion is located between -158 (upstream of the ATG start site) and +207 (in exon 1). The bh20 allele carries a point mutation in exon 3 (G9427 to A) that corresponds to the homeodomain region.

The Cbr-lin-11 ORF was amplified in two fragments using primer pairs cb-lin-11-up-1/cb-lin-11-down-7 and cb-lin-11-up-5/cb-lin-11-down-1. Sequencing primers were cb-lin-11-up-1, cb-lin-11-up-4, cb-lin-11-up-6, cb-lin-11-up-7, cb-lin-11-up-8, cb-lin-11-up-9, cb-lin-11-down-1, cb-lin-11-down-5, cb-lin-11-down-7, and cb-lin-11-down-8. Both lin-11 alleles, sy5336 and sy5368, affect splicing. sy5336 causes a G to A transition (G4043 to A) in the splicing acceptor site of intron 7 and is likely to disrupt intron 7 splicing. The sy5368 mutation affects the splicing donor site of intron 6 (G3340 to A) and is predicted to introduce a premature in-frame stop codon 52 nucleotides downstream.

Statistical analysis

Statistical analyses were performed using InStat 2.0 (GraphPad) Software. Two-tailed P values were calculated in unpaired t-tests, and values less than 0.05 were considered statistically significant.

RESULTS

Overview of the genetic screen

We screened for egg-laying defective (Egl) mutants after EMS mutagenesis of AF16 animals (see Materials and Methods for details). Of 39 Egl mutants identified, we report the characterization of 19 mutants. Seventeen of these fell into 13 complementation groups and were placed into four distinct phenotypic categories (Table 4). Of the remaining 2, lin(sy5212) and lin(sy5426), sy5212 is a fully penetrant Vul mutant and could not be outcrossed. In rare circumstances, VPC induction in sy5212 animals was observed only for P6.p. All other VPCs fused to hyp7 during the L2 and L3 stages. The other mutant, sy5426, has variable vulva defects (a combination of missing VPCs, uninduced VPCs, and abnormal morphogenesis) and could not be
uniquely classified. We used indel-based BSA, snip–SNP, and SNP-chip mapping approaches (Koboldt et al. 2010; Zhao et al. 2010) to localize the mutations to chromosomes (Table 3).

Class 1 mutants consist of three loci, each of which shows morphologically wild-type vulval development and a vulva-uterine connection (utse). The Egl phenotype of these animals is likely to result from defects in neuronal and/or muscle components of the egg-laying system. Class 2 is composed of two mutants, both of which are uncoordinated and frequently lack VPCs. In some cases, these animals lack a functional vulva and develop an Egl phenotype. Class 3 mutants are represented by three loci, each of which shows reduced VPC induction. The strongest allele in this class, bh23, causes a fully penetrant Egl defect. The largest phenotypic category, class 4, is composed of five loci. Mutations belonging to this class do not affect VPC induction but cause abnormal vulval invagination and morphology. The adults frequently have Pvl and Egl phenotypes.

**Class 1 mutants have defects in egg-laying components other than the vulva and utse**

The examination of vulval phenotype in class 1 mutants revealed that VPCs and their progeny were unaffected. Vulval cells invaginated correctly and gave rise to a morphology characteristic of the wild-type animals. Furthermore, the utse was normal and was located on the top of the vulval apex (data not shown). To examine defects in other components of the egg-laying system, we treated animals with drugs that affect neuronal and muscle activities. In *C. elegans*, hermaphrodite-specific neurons (HSNs) control egg-laying behavior (Croll 1975; Horvitz et al. 1982; Weisnhenker et al. 1995). In response to external cues, such as food, HSNs release serotonin (i.e., 5-hydroxytryptamine or 5-HT) into the neuromuscular synapse, which then acts on the postsynaptic receptors in the vulval muscle to stimulate the release of eggs. Authors investigating the role of HSNs have used serotonin and fluoxetine [a serotonin reuptake inhibitor that increases the amount of neurotransmitter available to post-synaptic receptors (Baldessarini 1996; Dempsey et al. 2005)] to characterize the neuronal basis of the Egl phenotype. Serotonin and fluoxetine drug assays can distinguish between pre- and postsynaptic defects (i.e., between HSN and vulva muscle). Mutants resistant to fluoxetine that lay eggs in the presence of exogenous serotonin are likely to have abnormal HSNs, whereas resistance to both drugs suggests a postsynaptic signaling defect. We found that *egl(sy5395)* animals, when exposed to serotonin, had a modest but consistent increase in the number of eggs laid compared with the control, but *egl(bh21)* and *egl(bh22)* were unaffected (Figure 1). Fluoxetine exposure had no obvious effect on any of the strains. These results suggest that the Egl phenotype in *sy5395* animals may be caused by abnormal differentiation of HSNs. In the case of *bh21* and *bh22* mutants, the cellular basis of the Egl phenotype remains to be identified.

**Class 2 mutants have defects in nuclear migration and include Cbr-unc-84**

The class 2 mutants *unc(sy5505)* and *unc(sy5506)* have fewer and more variable numbers of P cells in the ventral hypodermal region. Animals homozygous for either of these mutations move in a slow and uncoordinated manner. Microscopic observations revealed fewer than 12 P-cell nuclei in the ventral hypodermal region (Figure 2A). This phenotype was temperature sensitive, such that the loss of P cells was greater at higher temperatures (Figure 2A and data not shown). Nearly two-thirds of the animals had an Egl phenotype due to the absence of some or all of the P(5-7).p VPCs (Tables 4 and 5, Figure 3A). We also observed a hyp7 nuclear migration defect in the *sy5506* strain. Unlike wild-type animals where no hyp7 nuclei are observed in the dorsal hypodermis, *sy5506* worms had many hyp7 nuclei in this region (Figure 2, B and C).

In *C. elegans*, similar phenotypes are caused by mutations in two genes, *unc-83* (KASH domain) and *unc-84* (SUN domain), which affect nuclear migration during development (Malone et al. 1999; Starr et al. 2001; Sulston and Horvitz 1981). One of these, *unc-84*, is located on the right arm of chromosome X. We found that *sy5506* also maps to the right arm of chromosome X close to the bhP27 polymorphism (see Materials and Methods), a region that contains *Cbr-unc-84/CBG07416* and is syntenic to *unc-84*.

To further confirm that *unc(sy5506)* defines the *Cbr-unc-84* gene, we generated transgenic *sy5506* animals carrying an *unc-84* rescuing
A plasmid called pSL38 (McGee et al. 2006). The transgenic animals showed rescue of the hyp7 and P-cell nuclear migration defects (51% bhEx139 animals with normal hyp7 nuclear migration, n = 35, and 90% P nuclei present in ventral cord, n = 91, at 20°C, compared with 100% abnormal hyp7 nuclear migration and 42% P-cell nuclei, n = 23, in sy5506). The Egl and VPC induction defects in mutants also were rescued (69% of bhEx139 animals laying eggs, n = 94, compared with 56% in sy5506, n = 100; see Table 5 for VPC induction).

Finally, we sequenced the Cbr-unc-84 genomic region in unc (sy5506) animals and identified a 403-bp deletion covering parts of exons 6 and 7 (Figure 2D, also see Materials and Methods). These results demonstrate that sy5506 is an allele of Cbr-unc-84. In C. elegans, UNC-84 protein contains a SUN domain, a transmembrane domain and an intervening linker region (Malone et al. 1999; McGee et al. 2006). Based on the sequence alignment, the sy5506 mutation is located in the linker region of Cbr-UNC-84. In C. elegans, this region interacts with UNC-83 to facilitate localization of other cytoskeletal components that are crucial for nuclear positioning in hyp7 and P cells.

The phenotype of sy5505 animals differs from Cbr-unc-84(sy5506) in two respects. First, they are more sensitive to increased temperature as evidenced by their inability to grow at 29°C (Figure 2A). Second, no hyp7 migration defect was observed in sy5505 animals (data not shown). We also generated transgenic sy5505 strains carrying the unc-84 plasmid pSL38 (bhEx141 and bhEx142) but did not observe rescue of the mutant phenotype (Table 5 and data not shown). These results together with linkage data (Table 3) suggest that sy5505 is not allelic to Cbr-unc-84 and is likely a different gene. The phenotype of sy5505 is similar to mutations in unc-83 in C. elegans; however, the possibility that sy5505 is an allele of Cbr-unc-84 has not been tested.

Class 3 mutants exhibit reduced VPC induction

Four mutations define class 3 genes, all of which cause a reduction in the number of vulval progeny (see VPC induction score in Table 5) and abnormal invagination (Figure 3). In these animals, some or all P (3-8).p fail to divide and fuse with surrounding hypodermis ('F' fate; Table 5). The phenotype is weakest in lin(bh7) (only one VPC uninduced; Figure 3B) but fully penetrant in lin(bh23) (all VPCs uninduced; Figure 3E). The other two alleles, lin(bh14) and lin(bh20), are intermediate (Figure 3, C and D), with bh20 being somewhat more severe as determined by fewer cases of P6,p induction (15%; see Table 5) and rudimentary vulval invagination. This observation agrees well with the vulval induction score, cell lineage, and Egl penetrance of the animals (Tables 4, 5, and 6). The bh20 and bh23 mutations also cause abnormal folding of gonad arms and subtle uncoordinated phenotypes (data not shown).

Next, we examined the VPC induction defect in some detail. As the defect in bh7, bh14, and bh20 animals is predominantly limited to 2° precursors (P5.p and P7.p), we wanted to determine whether these two VPCs lack the potential to respond to an external signal and are

Figure 1 Egg-laying responses of class 1 mutants. The graph shows the average number of eggs laid by animals in M9 buffer (control) and serotonin and fluoxetine drug–containing solutions. The fold increase in egg laying in drug solution (over M9 buffer control) is plotted in the inset graph.

Figure 2 Nuclear migration defects in class 2 mutants and molecular analysis of Cbr-unc-84. (A) P-cell nuclei in the ventral cord region of mutants vary with temperature. At greater temperatures, fewer nuclei are visible. sy5505 animals are very sick at 29°C and could not be examined. Each data point consists of 25 or more animals. (B, C) Wild-type AF16 and sy5506 L1 stage animals, respectively. The hyp7 nuclei in the sy5506 animals fail to migrate and are located in the dorsal region (marked with vertical lines). Scale bar is 10 μm. (D) Open reading frame of Cbr-unc-84. sy5506 causes a 403-bp deletion.
Vulval precursor cells.

Only one of these animals had induction of both P5.p and P7.p (P5.p adopted 1°, P7.p 2°). The remaining VPCs adopted an ‘F’ fate. Similar manipulations in bh20 animals also caused P5.p and P7.p to be induced, albeit rarely (Table 7). Of the 19 cases, 4 had few vulval progeny. In two of these, P5.p appeared to adopt a 1°–like fate (no P7.p induction), whereas the other two had a hybrid 1°/2° lineage. This result is in contrast to intact bh20 animals in which P5.p and P7.p are never induced (Table 5). Taken together, these results suggest that in the absence of the central P6.p, the neighboring VPCs in these three mutants can be induced by the AC-mediated signal, and they can give rise to vulval tissue.

Overexpression of lin-3 suppresses the VPC induction defect in a subset of class 3 mutants

In <i>C. elegans</i>, LIN-3 signaling plays a role in maintaining the competence of VPCs by preventing their fusion with hyp7 (Myers and Greenwald 2007). This allows unfused VPCs to initiate Ras-MAPK

### Table 5 Vulval induction pattern in Class 2 and 3 mutants

| Class | Genotype       | VPC Induction Score | P3.p | P4.p | P5.p | P6.p | P7.p | P8.p | n     |
|-------|----------------|---------------------|------|------|------|------|------|------|-------|

VPC fates are classified into three categories: F, fused with hyp7 without division, 3*, fused with hyp7 after one cell division, I, induced (either 1°, 2°, or a hybrid fate that could not be uniquely classified). See Materials and Methods for details. For sy5505 and sy5506 animals missing VPCs were excluded from the analysis. VPC, vulval precursor cells.

aVPC induction is significantly higher compared to the parental strain, P < 0.0001.

unable to adopt an induced fate. In <i>C. elegans</i>, AC is necessary for VPC induction because it secretes LIN-3/EGF ligand that activates the LET-23/EGFR-LET-60/RAS-MPK-1/MAPK pathway in VPCs (Hill and Sternberg 1992; Kimble 1981). To this end, we ablated the central VPC, i.e., P6.p, during the L2 stage and examined the fates of the remaining VPCs. We predicted that P5.p and P7.p would receive similar to AF16. Thus, P5.p and P7.p were induced in all cases (Table 7). The frequencies of induced VPCs were much lower in bh7 animals (Table 7). In total, five of nine animals had some vulval tissue as a result of P5.p and P7.p induction (P5.p adopted 1° fate in three cases and P7.p in the remaining two). Only one of these animals had induction of both P5.p and P7.p (P5.p 1° and P7.p 2°). The remaining VPCs adopted an ‘F’ fate. Similar manipulations in bh20 animals also caused P5.p and P7.p to be induced, albeit rarely (Table 7). Of the 19 cases, 4 had few vulval progeny. In two of these, P5.p appeared to adopt a 1°–like fate (no P7.p induction), whereas the other two had a hybrid 1°/2° lineage. This result is in contrast to intact bh20 animals in which P5.p and P7.p are never induced (Table 5). Taken together, these results suggest that in the absence of the central P6.p, the neighboring VPCs in these three mutants can be induced by the AC-mediated signal, and they can give rise to vulval tissue.

Overexpression of lin-3 suppresses the VPC induction defect in a subset of class 3 mutants

In <i>C. elegans</i>, LIN-3 signaling plays a role in maintaining the competence of VPCs by preventing their fusion with hyp7 (Myers and Greenwald 2007). This allows unfused VPCs to initiate Ras-MAPK

Figure 3 Vulva phenotypes of class 2 and 3 mutants. Arrows point to the center of invagination. Animals were examined at the mid-L4 stage. (A) Fewer VPCs are present in sy5506 animals due to a defect in P-cell nuclear migration. In this case P6.p and P7.p are induced to form the vulva. P5.p and P8.p are missing. (B) One or more VPCs in bh7 animals remain uninduced. In this example, P5.p and P6.p are induced. P4.p and P7.p have adopted an F fate (asterisks). (C, D) bh14 and bh20 animals showing a similar vulval morphology defect. In both cases invagination is formed by P6.p progeny, whereas P5.p and P7.p have adopted an F fate (asterisks). (E) A bh23 animal showing no vulval induction. All VPCs have adopted an F fate. Scale bar is 10 μm.
signaling to promote vulval induction. A similar mechanism could operate in *C. briggsae* as well, which would be consistent with the results of our aforementioned cell ablation experiments in which P5.p and P7.p often were induced in the absence of P6.p, possibly by responding to a greater level of gonad-derived signal. To test this directly, we monitored the effect of increased doses of LIN-3/EGF on VPC induction in *bh7*, *bh14*, and *bh20* animals. A *C. elegans* lin-3 transgene under the control of a heat shock promoter was introduced in *C. briggsae*. This transgene was previously used in *C. elegans* and causes a Muv phenotype (Katz et al. 1995). Heat shocks given during early stages (0-18 hr post-L1) and late stages (30 hr post-L1 and beyond) had no effect on vulval development (Figure 4A and data not shown). However, 20-28 hr post-L1, animals (VPC one-cell stage, Pn.p) developed a Muv phenotype when subjected to heat shock (Figure 4A). The Muv penetrance was highest at the 24 hr post-L1 time point (58%, see Figure 4A, AC visible in all cases at the time of heat shock), which corresponds to the late-L2/early-L3 stage and precedes the division of dorsal uterine precursors. All VPCs were induced, although P3.p appeared to be somewhat refractory in this assay (Figure 4C).

Next, we examined the effect of lin-3 overexpression in *bh7*, *bh14* and *bh20* animals. Heat shocks at the 24 hr post-L1 time point induced a Muv phenotype in *bh7* animals similar to the control (Figure 4B). The *bh14* animals showed a similar but reduced response (Figure 4B). In contrast, no Muv phenotype was observed in *bh20* animals (Figure 4B). Examination of cell fates revealed that greater doses of LIN-3 induced VPCs in all 3 genetic backgrounds, including *bh20* in which P6.p was threefold more likely to be induced compared to the control (Figure 4C). These results show that increased VPC induction in class 3 mutants is most likely caused by the activation of a pathway homologous to LIN-3/EGF signaling in *C. elegans*.

### Table 6 Vulval cell lineage analysis of class 3 and 4 mutants

Cells attached to the cuticle are underlined. D, division plane not observed; L, longitudinal; O, oblique; N, no cell division; n, number of animals scored; S, cell fused with syncytium; T, transverse plane of cell division.

### Table 7 Effect of cell ablations on VPC fates in class 3 mutants

| Genotype  | VPC Fate (Induced/Uninduced) | |
|-----------|-----------------------------|---|
|           | P3.p | P4.p | P5.p | P6.p | P7.p | P8.p | n |
| mfIs5(egl-17::gfp) | 0/100 | 30/70 | 100/0 | x | 100/0 | 70/30 | 10 |
| lin(bh7)  | 0/100 | 67/33 | 100/0 | x | 100/0 | 70/30 | 6  |
| lin(bh14) | 0/100 | 0/100 | 33/67 | x | 22/78 | 0/100 | 9  |
| lin(bh20) | 0/100 | 0/100 | 15/85 | x | 3/95 | 0/100 | 19 |

x’ denotes VPCs that were ablated during the early-L2 stage. See Table 5 for a description of VPC fates. Uninduced refers to F and 3’/C176 fates. n, number of animals scored; VPC, vulval precursor cells.

Class 3 mutations *bh20* and *bh23* are alleles of **Cbr-lin-39**

The cell fusion defect in class 3 mutants was similar to that of *C. elegans* with mutant Hox gene *lin-39* alleles that cause P(3-8).p cells to
suffer to surrounding hypodermis (Clark et al. 1993). Therefore, we wanted to determine whether any of these are alleles of Cbr-lin-39. Using Indel mapping, we had earlier placed lin(bh20) on the right arm of chromosome 3 (Koboldt et al. 2010). This region includes C. elegans lin-39 ortholog (http://www.wormbase.org). Therefore, we took a candidate gene approach and sequenced the exonic regions of Cbr-lin-39 in bh20 animals. A single point mutation (G9427 to A) was found that is predicted to replace a conserved arginine (R) with glutamine (Q) at position 169 in the homeodomain region (Figure 5A).

Considering that lin(bh23) animals show a similar but more severe VPC induction defect, we suspected that this could be another allele of Cbr-lin-39. Sequencing of the Cbr-lin-39 region in this strain identified a 364 bp deletion affecting the promoter and translational start site (Figure 5A).

We also carried out a transgene rescue experiment for lin(bh20) animals using a C. elegans lin-39-rescuing genomic DNA clone. Examination of transgenic animals revealed a rescue of the VPC competence defect in both cases (Table 5). The Egl defect also was rescued in these lines (animals laying eggs: bhEx132 83%, n = 29 and bhEx134 24%, n = 124; compared with 4% in bh20 alone, n = 140). In C. elegans, lin-39 acts at multiple times during vulval development. In the L1 and L2 stages, it prevents Pn.p cells from fusing to hyp7 (Clark et al. 1993). Later on in stage L3, it is up-regulated by Ras signaling to promote vulval induction (Malof and Kenyon 1998). To determine whether Cbr-lin-39 mutants cause cell fusion defects in C. briggsae, we used a junction-associated marker dpy-1::GFP (Seetharaman et al. 2010). In wild-type, both P5.p and P6.p remain unfused in the late-L1 and L2 stages and become competent to form the vulval tissue (Figure 5B). In the majority of bh20 animals, the corresponding cells were fused by early-to-mid-L2 stage (60.7%, n = 28). In the remaining cases, one or two Pn.p cells were protected (P5.p and P6.p 21.4% and P6.p alone 17.8%, n = 28; Figure 5C). The proportion of animals with unfused cells was much lower at later stages and was limited to P6.p (mid-L3 stage: P6.p 30.8%, n = 13; L4 stage: P6.p 12.5%, n = 24). As it has been previously reported that the spacing of Pn.p cells in the ventral hypodermis is less regular in C. elegans lin-39 mutants (Clark et al. 1993), we measured VPC spacing in Cbr-lin-39 animals. Our results agreed with the findings in C. elegans and revealed that both Cbr-lin-39 alleles cause greater variability in VPC placement (Figure 5, D and E). Although all inter-VPC distances were affected, the phenotype was most pronounced in the P6.p-P7.p pair. Interestingly, the P5.p-P6.p pair in C. briggsae showed the reverse of C. elegans.

bh20 is epistatic to Cbr-pry-1(sy5353)

We recently demonstrated a conserved role for pry-1-mediated Wnt signaling in C. elegans vulval induction (Seetharaman et al. 2010). In Cbr-pry-1 animals, P5.p and P6.p are always induced, but P7.p often is not (Figure 5F). The inability of P7.p to contribute to vulval tissue is likely due to a change in cell fate as judged by its small nucleus and P12.pa-like appearance. Cbr-pry-1 mutants also exhibit ectopic induction of P3.p and P4.p and to some extent P8.p, resulting in the formation of multiple ventral protrusions (pseudoovules). Thus, both a lack of induction (P7.p) and excessive induction phenotypes are observed in Cbr-pry-1 animals.

Given that lin-39 acts genetically downstream of pry-1 in C. elegans (Gleason et al. 2002), we examined the genetic interaction of Cbr-lin-39 with Cbr-pry-1. As expected, Cbr-lin-39(bh20) suppressed the increased induction phenotype of Cbr-pry-1(sy5353). Ectopic vulval induction was inhibited due to VPCs frequently adopting F fates (n = 42; P6.p was induced in 24% cases; Figure 5G). However, the small nucleus phenotype of P7.p, P8.p, and P11.p was not suppressed by bh20 (Figure 5G and data not shown). Therefore, one of the following may be true: either the residual activity of Cbr-lin-39 in bh20 animals is greater than the threshold needed for VPC size specification or Cbr-lin-39 mediates only a subset of Cbr-pry-1 function.

Class 4 mutations affect vulval invagination and morphology

This class consists of seven mutants, all of which have defective vulval morphology (Table 8). Microscopic observations revealed that the
animals have the correct number of VPCs and their progeny but the cells fail to invaginate correctly (Figure 6). In addition to the Egl phenotype, the adults exhibit a Pvl phenotype (Table 8). Complementation and mapping experiments revealed a total of five loci, three of which are located on chromosome 1 with the others on chromosome 5 and the X chromosome (Table 3). Two of the chromosome 1 genes have additional alleles (bh13 and sy5197 on the left arm, sy5336 and sy5368 close to the center).

The sy5336 and sy5368 mutations cause a fully penetrant Egl phenotype. A distinctive feature of these animals, with regards to egg laying, is rudimentary vulval invagination and defects in the connection of the vulva to the uterus (Figure 6B). The analysis of VPC

---

**Figure 5** Genomic organization and mutant phenotypes of lin-39. (A) *C. briggsae* lin-39 open reading frame. Exons are represented by thick lines. The positions of the homeodomain and two mutations are shown. (B, C) Unfused VPCs revealed by *dlg-1::GFP* expression. (B) Wild-type AF16 and (C) bh20 L2 stage animals. In this bh20 animal only P6.p ring is visible. (D, E) Inter-VPC spacing in *lin-39* alleles in *C. elegans* and *C. briggsae*. VPCs are irregularly spaced in mutants, which is reflected in greater SDs. (F, G) Excessive induction of VPC phenotype in sy5353 animals is suppressed by bh20. (F) sy5353 and (G) bh20; sy5353 double mutant. VPC fates are shown as Fused, 3+ induced (1+ and 2+) and small (P12.pa-like).
lineages revealed errors in cell divisions and adherence properties of some of the 2° lineage cells (Table 6). Other phenotypes included low brood size (sy5336: 21 ± 5, n = 11; sy5368: 10 ± 2, n = 12) and defective mating. The hermaphrodites are unable to mate at all, whereas males can mate, although very poorly (data not shown).

The bh13 and sy5197 animals are small and mildly sluggish. Some also have abnormally folded gonad arms. These phenotypes accompany Egl and vulval invagination defects in both outcrossed strains (Tables 4 and 8, Figure 6C), suggesting they are linked to a single gene. We looked at the vulval morphology in L4 stage animals and found that the 1° lineage cells are abnormally placed. In addition, the utse cannot be clearly observed in these animals (Figure 6C). A combination of the vulva and utse defects appears to cause a physical block in the egg-laying passage.

The vulval morphology defect in bh26 animals shares some similarity with that of bh13 animals (Figure 6D compared with Figure 6C). Specifically, the nuclei of the 1° lineage cells fail to migrate correctly, thereby blocking the connection between the vulva and the uterus. We also observed defects in the migration of the AC and a lack of utse (Figure 6D). Other defects included abnormal gonad arms and sterility.

The remaining two class 4 mutants, lin(bh25) and lin(sy5425), have weaker Egl and Pvl phenotypes compared with others in this category (Table 8). In both cases, vulval cells invaginate and form finger-like structures, but the overall morphology is abnormal (Figure 6, E and F). The penetrance of the vulval defect is greater in sy5425 compared with bh25, although an opposite trend was observed for the Egl phenotype. We also noted that the utse is somewhat thicker in bh25 animals (Figure 6E), although its contribution to the Egl phenotype is unclear. Interestingly, some sy5425 animals showed ectopic P4.p and P8.p induction. This phenotype is present in the outcrossed strain, so it is either caused by the same mutation or another very closely linked mutation. More work is needed to distinguish between these two possibilities. We also observed significant embryonic and early larval lethality in the sy5425 strain (18%, n = 284).

### Cbr-lin-11 mutations disrupt vulva and utse morphogenesis

The vulva and utse defects of lin(sy5336) and lin(sy5368) animals strongly resemble those of C. elegans lin-11 mutants (Ferguson et al. 1987; Newman et al. 1999). In addition, the thermotaxis defect of the animals is also similar ([Hobert et al. 1998] Figure 7B), which is reflected in their lack of preference to the cultivation temperature. Therefore, we carried out transgene rescue experiments to examine whether these two lines carry mutant alleles of Cbr-lin-11. Stable lines carrying a 19-kb genomic clone of C. elegans lin-11 (bhEx78 and bhEx148, on the sy5336 genetic background) showed rescue of the vulva, utse, and Egl defects (bhEx78: 47% wild-type vulva and utse, n = 32, non-Egl 8%, n = 25; bhEx148: 71% wild-type vulva and utse, n = 31, non-Egl 12.5%, n = 48; compared with Cbr-lin-11 mutants in Table 8). We also sequenced the Cbr-lin-11 locus in both alleles and identified molecular changes that are predicted to disrupt splicing in the homeobox region (Figure 7A, also see Materials and Methods).

The aforementioned rescue experiments demonstrate that C. elegans lin-11 can substitute for Cbr-lin-11 function in C. briggsae and suggest that lin-11 function is evolutionarily conserved. This is also supported by the analysis of the cDNA and protein sequences. The lin-11 cDNA (C. elegans: 1218 bp, 10 exons; C. briggsae: 1239 bp, 10 exons) (see Figure S3 for C. briggsae sequence) is 80% conserved, and the corresponding proteins are 87% identical (94% similar).

To examine the vulval defect in Cbr-lin-11 animals, we used two GFP-based markers Cbr-egl-17 (mfIs5) and Cbr-zmp-1 (mfIs8). In C. elegans, egl-17 and zmp-1 have been used extensively in cell fate specification studies (Cui and Han 2003; Gupta et al. 2003; Inoue et al. 2002). The dissection of the regulatory regions of these genes has revealed evolutionarily conserved sequences (Kirouac and Sternberg 2003). In the wild-type C. briggsae, the earliest expression of Cbr-egl-17::gfp is observed in mid/late-L4 stage animals in the presumptive vulC and vulD (Seetharaman et al. 2010). In the case of Cbr-zmp-1::gfp, GFP fluorescence is primarily observed in the presumptive vulE (Seetharaman et al. 2010). We found that the expression of both markers was absent in Cbr-lin-11(sy5336) animals (Table 9). This result supports our previous findings and a crucial role of lin-11 in vulval cell differentiation (Gupta et al. 2003).

Despite the high conservation in lin-11 sequence and function, we did observe an interesting difference in the AC placement between the two species. Unlike C. elegans lin-11 animals, in which ACs fail to migrate and are located on the vulval apex in most animals (n389: 81.1%, n = 53; Figure 7C), no such phenotype was observed in C. briggsae (sy5336: 0%, n = 47 and sy5368: 0%, n = 52; Figure 7D).

### DISCUSSION

We report the isolation and characterization of mutations in 13 genes in C. briggsae that are involved in the development and function of the...
studies revealed that although the functions of Cbr-daf-3 (Smad), and Egl or another reason. It is worth pointing out that in our experience, Egl or whether it results from the lack of saturation in the screen processes between temperature sensitivities. Thus, comparative genetics approaches are conserved in C. briggsae, the two species exhibit differences in their evolutionary changes in the mechanism of vulva formation. Screens in C. briggsae were previously carried out to identify dauer pathway genes (Inoue et al. 2007). The screen identified several mutations, including alleles of Cbr-daf-2 (insulin receptor), Cbr-daf-3 (Smad), and Cbr-daf-4 (TGF-β family receptor). Genetic studies revealed that although the functions of C. elegans orthologs are conserved in C. briggsae, the two species exhibit differences in their temperature sensitivities. Thus, comparative genetics approaches are useful for revealing the similarities and differences in biological processes between C. elegans and C. briggsae.

Egl phenotype-based genetic screens were first carried out in C. elegans and led to the identification of many genes involved in vulval development (Ferguson and Horvitz 1985; Trent et al. 1983). Characterization of their function revealed a genetic pathway for the formation of the vulva (Ferguson et al. 1987). During the past decade and a half, this knowledge has been extended to other distant species, such as P. pacificus and O. tipulae, resulting in a better understanding of the evolutionary changes in the mechanism of vulva formation. Screens in O. tipulae have identified several mutations affecting vulva formation. Although the majority of these cause defects in VPC division and competence (Dichtel et al. 2001; Louvet-Vallee et al. 2003), others affecting vulva centering and hyper- and hypo-induced phenotypes also have been identified (Dichtel et al. 2001). Similar mutant classes have been found in P. pacificus screens as well (Eizinger et al. 1999; Sommer 2005). Compared with C. elegans, the phenotypic spectrum in these two species is quite different. For example, mutations affecting Pn.p fate (e.g., 1° converted to 2° or 3°) were recovered quite frequently in C. elegans but not in O. tipulae or P. pacificus. Interestingly, our screens in C. briggsae also revealed differences from C. elegans. We did not find Pn.p fate mutants, and one-half of the mutants examined show defects in cell invagination and morphogenesis (Table 8, Figure 8). It is not clear whether this phenotypic distribution is typical in C. briggsae or whether it results from the lack of saturation in the screen or another reason. It is worth pointing out that in our experience, Egl animals in C. briggsae are more difficult to identify in a standard F2 screen in the presence of predominantly non-Egl worms. This may be at least partly caused by the tendency of C. briggsae to retain fewer eggs in the uterus compared to C. elegans (B. P. Gupta, unpublished results; T. Inoue and M. A. Felix, personal communications). The difficulty in isolating Egls could have limited the recovery of vulvaspecific mutants and the phenotypic classes in our screens. Future genetic screens using different approaches will help to address this issue. Furthermore, combining a vulva-specific GFP reporter with an Egl phenotype may be a useful approach, as it will minimize the recovery of non-vulva mutations.

Phenotypic classes recovered in our screen
We have isolated four phenotypic classes of worms, all of which affect egg laying. Mutations in one of these (class 1) have normal vulva and utse morphologies. To investigate the role of sex muscles and HSNs, we used serotonin and flutoxetine drugs to induce egg laying. sy5395 mutants showed a mild but obvious increase in egg laying in response to serotonin, suggesting that the muscle function is intact. However, bh2 and bh21 did not respond to any of the drugs, suggesting that muscle function may be impaired.

The class 2 mutations sy5505 and sy5506 affect nuclear migration in a temperature-dependent manner. Both alleles cause animals to develop Egl and Unc phenotypes due to the failure of P nuclei to migrate into the ventral cord region. The phenotype of unc(sy5506) animals can be rescued by a C. elegans unc-84 transgene, suggesting that sy5506 is an allele of Cbr-unc-84. This conclusion is also supported by our mapping and allele sequencing data. The remaining two classes of mutations alter the number of vulval progeny and vulval invagination. Cbr-lin-39 is required for the maintenance of VPC competence and appears to act in egg-laying system. To date, this is the largest set of genes identified by a forward genetics approach in this species. Ten of these genes are involved in various steps of vulval development (Figure 8). Transgene rescue and molecular analyses have revealed that three genes are orthologs of C. elegans unc-84, lin-39, and lin-11. Together, these mutant strains serve as valuable tools for comparative and evolutionary studies. Another genetic screen in C. briggsae was previously carried out to identify dauer pathway genes (Inoue et al. 2007). The screen identified several mutations, including alleles of Cbr-daf-2 (insulin receptor), Cbr-daf-3 (Smad), and Cbr-daf-4 (TGF-β family receptor). Genetic studies revealed that although the functions of C. elegans orthologs are conserved in C. briggsae, the two species exhibit differences in their temperature sensitivities. Thus, comparative genetics approaches are useful for revealing the similarities and differences in biological processes between C. elegans and C. briggsae.

Phenotypic classes recovered in our screen
We have isolated four phenotypic classes of worms, all of which affect egg laying. Mutations in one of these (class 1) have normal vulva and utse morphologies. To investigate the role of sex muscles and HSNs, we used serotonin and flutoxetine drugs to induce egg laying. sy5395 mutants showed a mild but obvious increase in egg laying in response to serotonin, suggesting that the muscle function is intact. However, bh2 and bh21 did not respond to any of the drugs, suggesting that muscle function may be impaired.

The class 2 mutations sy5505 and sy5506 affect nuclear migration in a temperature-dependent manner. Both alleles cause animals to develop Egl and Unc phenotypes due to the failure of P nuclei to migrate into the ventral cord region. The phenotype of unc(sy5506) animals can be rescued by a C. elegans unc-84 transgene, suggesting that sy5506 is an allele of Cbr-unc-84. This conclusion is also supported by our mapping and allele sequencing data. The remaining two classes of mutations alter the number of vulval progeny and vulval invagination. Cbr-lin-39 is required for the maintenance of VPC competence and appears to act in egg-laying system. To date, this is the largest set of genes identified by a forward genetics approach in this species. Ten of these genes are involved in various steps of vulval development (Figure 8). Transgene rescue and molecular analyses have revealed that three genes are orthologs of C. elegans unc-84, lin-39, and lin-11. Together, these mutant strains serve as valuable tools for comparative and evolutionary studies. Another genetic screen in C. briggsae was previously carried out to identify dauer pathway genes (Inoue et al. 2007). The screen identified several mutations, including alleles of Cbr-daf-2 (insulin receptor), Cbr-daf-3 (Smad), and Cbr-daf-4 (TGF-β family receptor). Genetic studies revealed that although the functions of C. elegans orthologs are conserved in C. briggsae, the two species exhibit differences in their temperature sensitivities. Thus, comparative genetics approaches are useful for revealing the similarities and differences in biological processes between C. elegans and C. briggsae.

### Table 9 Expression of vulval cell fate markers in Cbr-lin-11 mutants

| Genotype | GFP Fluorescence in Vulval Progeny | n |
|----------|-----------------------------------|---|
| mfl5 (egl-17::gfp) | vulC: 79%, vulI and vulJ: 21% | 113 |
| sy5336; mfl5 | None | 104 |
| mfl8 (amp-1::gfp) | vulA: 2%, vulE: 91%, vulA and vulE: 7% | 128 |
| sy5336; mfl8 | None | 61 |

GFP, green fluorescent protein; n, number of animals scored.
downstream of Cbr-pry-1/axin-mediated Wnt signaling. Cbr-lin-11 controls vulval cell differentiation and tissue morphogenesis. Both genes belong to conserved families of transcription factors (the Dfd/Scr-related Hox family and the LIM-Hox family, respectively).

**Nuclear migration in C. briggsae is mediated by a conserved SUN domain protein**

Nuclear migration plays important roles in diverse cellular processes, including cell division, cell polarity and cell migration. In *C. elegans*, well-studied nuclear migration events are observed with the hyp7 syncytium (dorsal side of the hypodermis) and a set of hypodermal blast cells (P cells) that form the vulva. Genetic analysis of these events has revealed that UNC-83 (KASH domain) and UNC-84 (SUN domain) proteins form a bridge-like structure to connect the nucleus to microtubules, motor proteins, and other cytoskeletal components. The movement of Kinesin and Dynein motors in a coordinated manner causes the nucleus to move in a specific direction. The vulval defects in *C. briggsae* sy5505 and sy5506 animals are typical of unc-83 and unc-84 mutants. Both alleles exhibit a temperature-sensitive phenotype and display Egl and Unc phenotypes. The phenotypes of sy5506 animals can be efficiently rescued by a *C. elegans* unc-84 genomic clone, which demonstrates that unc-84 plays a conserved role in nuclear migration in both species.

**Genes affecting cell fusion in C. briggsae**

We isolated two alleles of *Cbr-lin-39*, both of which prevent VPC induction. In *C. elegans*, P(3-8).p escape fusion in the L1 and L2 stages and remain competent to respond to induction during the L3 stage (Sternberg 2005). This process is regulated by *lin-39* (Clark et al. 1993). The expression of *lin-39* at the L2 stage appears to be partly controlled by BAR-1/β-catenin-mediated Wnt signaling because in *bar-1* mutants, *lin-39* expression in VPCs is reduced, resulting in fusion of some VPCs to the hyp7 syncytium (Eisenmann et al. 1998). Our experiments on *Cbr-lin-39* suggest that the function of *lin-39* in VPC competence is conserved in *C. briggsae*. This finding is supported by the analysis of mutant phenotype, rescue experiments, cell fusion studies using the *dlg-1::GFP* marker, and genetic interaction with *Cbr-pry-1* (Axin family). Our previous results involving RNA interference-mediated knockdown of *Cbr-lin-39* (Seetharaman et al. 2010) also support these findings.

*lin-39* orthologs also have been identified in *O. tipulae* and *P. pacificus*. *Ott-lin-39* appears to control VPC competence by...
preventing fusion of Pn.p cells in the late-L1/early-L2 stages (Louvet-Vallee et al. 2003). However, the function of Ppa-lin-39 appears to have diverged. In Ppa-lin-39 mutants, VPCs undergo programmed cell death instead of fusing with the hypodermis (Eizinger and Sommer 1997). Taken together, these findings suggest that although lin-39 function is conserved in Caenorhabditis and Osechius species, it has acquired new roles in Pristionchus. In the future, the analysis of the role of lin-39 in additional nematode species will allow for a more detailed comparison of its role in vulval development.

In addition to Cbr-lin-39, we have uncovered two other loci, lin (bh7) and lin(bh14), that control VPC competence. The phenotype of both mutants is weaker than that of bh20 animals, perhaps due to weak hypomorphic alleles. Alternatively, these genes may have some redundant function. More alleles are required to distinguish between these two possibilities. The induction of P5.p and P7.p in bh7 and bh14 animals is frequently affected. To test the induction potential of these two VPCs, we carried out two complementary experiments. We examined their pattern of division after ablation of P6.p. Furthermore, the effect of lin-3 overexpression was investigated. We found that in the absence of P6.p, the P5.p and P7.p cells were induced to various extents, suggesting that these VPCs can respond to inductive signal. This conclusion is strongly supported by the lin-3 dosage experiments. High doses of lin-3 during the L2 stage caused ectopic VPC induction, resulting in a Muv phenotype. We can therefore conclude that class 3 genes interact with a LIN-3-like inductive signal to regulate VPC competence in C. briggsae.

**lin-11 is a key regulator of vulval morphogenesis**

**lin-11** is a founding member of the LIM homeobox family of genes. Mutations in **lin-11** were originally isolated in genetic screens for worms that failed to lay eggs (Ferguson and Horvitz 1985). Subsequently, phenotypic analyses showed a wide-range of defects affecting vulval morphology (Freyd et al. 1990; Gupta et al. 2003), utse formation (Newman et al. 1999), and neuronal differentiation (Hobert et al. 1998; Sarafi-Reinach et al. 2001). C. briggsae **lin-11** mutants exhibit defects in the egg-laying system similar to those observed in C. elegans **lin-11** animals. Thus, vulval cells fail to invaginate, and a functional connection between the vulva and the uterus is not established. These phenotypes can be rescued by a C. elegans **lin-11** genomic fragment, suggesting that **lin-11** regulatory and coding sequences are evolutionarily conserved. This supports our previous conclusions on the conservation of **lin-11** regulation by Wnt and LIN-12/Notch signaling pathways in the vulva and π cell differentiation (Marri and Gupta 2009).

Outside the reproductive system, **lin-11** also is involved in the differentiation of several olfactory and chemosensory neurons (Sarafi-Reinach et al. 2001). We have not yet characterized the neuronal role of Cbr-lin-11 in detail, but we have found that Cbr-lin-11 mutants have a thermotaxis defect similar to that reported in C. elegans **lin-11** animals. Thus, similar to the egg-laying system, the role of **lin-11** in thermosensory behavior is also conserved. The recovery of Cbr-lin-11 alleles provides a unique opportunity to investigate the mechanism of cell differentiation in C. briggsae and C. elegans.

**DSD in C. briggsae vulva formation**

Kiontke et al. 2007 had earlier reported variations in several steps of vulva formation in Rhabditid species. These included changes in Pn.p cell competence, cell division pattern, and vulva position. The phenotypic analysis of C. briggsae vulva mutants and molecular cloning of the 3 loci in which the mutations are located has revealed DSD in homologous processes. We observed interesting differences in at least three cases. First, the P5.p-P6.p inter-VPC distance in **lin-39** mutants tends to be lower in C. briggsae than in C. elegans. Second, **lin-39** does not interact with **pry-1** to enhance the small nuclear size phenotype of posterior Pn.p cells in C. briggsae as it does in C. elegans (Penigault and Felix 2011b). Finally, Cbr-lin-11 animals do not show AC migration defects, which is one of the hallmarks of **lin-11** mutants in C. elegans. These results reveal the differences in developmental mechanisms that exist despite conservation of vulval morphology in these two species.

**C. briggsae as a model for the study of vulval development**

C. briggsae is increasingly being used in comparative developmental and evolutionary studies. In recent years, a number of publications have described processes such as sex determination (Guo et al. 2009; Hill et al. 2006; Kelleher et al. 2008), dauer formation (Inoue et al. 2007), pheromone receptor signaling (McGrath et al. 2011), embryogenesis (Lin et al. 2009; Zhao et al. 2008), and vulva formation in C. briggsae (Felix 2007; Hoyos et al. 2011; Marri and Gupta 2009; Penigault and Felix 2011a; Seetharaman et al. 2010). The findings have revealed similarities and differences in developmental processes.

The analysis of the vulva precursor fates in C. briggsae has revealed the role of conserved signaling pathway genes such as Ras, Notch, and Wnt. However, a detailed examination of gene function and pathways could not be carried out due to the lack of mutations affecting specific steps in the vulval development process. The mutations described in this study represent the first systematic effort in C. briggsae to investigate the genetic basis of vulva formation. Future work is needed to reveal the mechanism of gene function and to further compare C. briggsae to C. elegans. The results will ultimately help clarify how distinct processes form almost identical vulval structures in these two species.

**ACKNOWLEDGMENTS**

We thank Takao Inoue and Shahla Gharib for isolating **lin-11** alleles, Veena Deekonda, Nayasta Ademmana, and Carly Ching for assistance in experiments, and Takao Inoue for critical comments. Two of the transgenic strains mfIs5 and mfIs8 were kindly provided by Marie-Anne Felix (Institut Jacques Monod). The genetic screens were carried out in the laboratory of Paul Sternberg. This work was supported by the Natural Sciences and Engineering Research Council Discovery grant to B.P.G. Work in the laboratory of D.G.M. was supported by Genome Canada, Genome British Columbia and the Canadian Institutes for Health Research.
