Abstract

We calculate, using a Z-peak subtracted representation of four-fermion processes previously illustrated for the case of electron-positron annihilation into charged lepton-antilepton, the corresponding expressions of the new physics contributions for the case of final quark-antiquark states, allowing the possibility of both universal and non universal effects. We show that, in each case, the main result obtained for the final lepton channel can be generalized, so that every experimentally measurable quantity can be expressed in terms of input parameters measured on Z resonance, of $\alpha(0)$ and of a small number of subtracted one loop expressions. Some examples of models are considered for several c.m. energy values, showing that remarkable simplifications are often introduced by our approach. In particular, for the case of a dimension-six lagrangian with anomalous gauge couplings, the same reduced number of parameters that would affect the observables of final leptonic states are essentially retained when one moves to final hadronic states. This leads to great simplifications in the elaboration of constraints and, as a gratifying byproduct, to the possibility of making the signal from these models clearly distinguishable from those from other (both universal and non universal) competitors.
1 Introduction

At the end of this year, LEP1 will have ultimated its last run. Although SLC will keep performing for a few more years, with some (potentially, extremely interesting) longitudinal polarization asymmetries still to be investigated, one can conclude that the high precision SM test program, based on measurements of electron-positron annihilation into fermions on top of Z resonance, has essentially been concluded. No deviations from the SM prediction was found (with the only possible remarkable exception of the partial Z decay width into $b\bar{b}$) at the achieved precision level of few permille, and for a large set of experimental variables (partial and total Z widths and asymmetries) that have been extremely carefully analyzed in these years. Stated otherwise, and keeping in mind the previous remark, no virtual effects of new physics have been evidentiated by the several measurements at the few permille level performed in the considered four-fermion process at $\sqrt{q^2} = M_Z$ ($q^2 = (P_e + P'_e)^2$). Thus, the only information achieved on several candidate models comes from a number of bounds, that can be, depending on the case, drastic (e.g for most common technicolour models) or extremely mild (e.g. for the simplest supersymmetric extension -MSSM- of the SM).

Technicolour and supersymmetry are not the only alternatives to the SM whose virtual effects have been tested by LEP1 and SLC. In particular, signals of models with "anomalous" gauge couplings have been also searched for and the negative results have led to some corresponding bounds. But in this case the obtained results are somehow less clean. Leaving aside a number of technical points, one difficulty for these models is also related to the number of involved parameters, essentially too large, even in the presence of the considerable number of LEP1, SLC high precision measurements.

In a near future, electron-positron annihilation at $\sqrt{q^2} \simeq 2M_Z$ (LEP2) and (perhaps in a "not too near" future) at $\sqrt{q^2} = 500GeV$ (NLC) will be measured. For obvious reasons, the relative accuracy of the various measurements will be worse than at LEP1, SLC, moving from the few permille to the few percent level. For final fermion-antifermion state it is also likely that the number of measurable experimental variables will decrease. This might lead to the conclusion that the search of virtual effects of new physics in these future processes will be, least to say, tough for a number of potentially interesting models, in particular for those whose effect on top of Z resonance are described by a large number of parameters.

In a previous paper, we have tried to propose a solution to this problem for the case of final (charged) lepton-antilepton states. Our starting point was the (known) fact that a theoretical analysis of virtual one loop effects can be eased by a proper choice of the "input" parameters. For instance, for the description of physics of electron-positron on Z resonance, the introduction of the Fermi constant $G_\mu$ to replace $M_W$ is quite useful. But for a theoretical description of electron-positron annihilation at higher energies, we showed in [9] that $G_\mu$ does not seem to be the best choice if an investigation of models of new physics is the theoretical goal. In particular, a self-contained representation of final lepton-antilepton states can be given where $G_\mu$ is "traded" and the new input parameters are the $Z$ leptonic width $\Gamma_l$ and the "effective" $s^2_{\text{eff}}(M_Z^2)$ measured by LEP1 and SLC.
Once these quantities (together with the physical electric charge $\alpha_{\text{QED}}(0)$) are introduced, the rest of the representation only contains three subtracted quantities (called $\Delta\alpha$, $R$ and $V$ in ref.[9]) whose theoretical properties for what concerns the effects of a number of models of new physics appear undeniably, least to say, interesting, in the sense that their actual calculation turns out to be generally much easier (this is simply due to the fact that a number of model’s parameters, whose theoretical features might be less pleasant, are often ”reabsorbed” in the new $Z$-peak inputs $\Gamma_l$ and $s_{\text{eff}}^2(M_Z^2)$). We also showed in ref.[9] that, at the realistic expected experimental conditions of future $e^+e^-$ colliders, the loss of theoretical accuracy introduced by this ”$G_\mu$ trading” does not produce any observable effect. We concluded that the proposed ”$Z$-peak subtracted” representation was a good approach to investigate new-physics effects in the final lepton-antilepton channel.

The aim of this paper is that of showing that the same method, with identical conclusions, can be generalized to the case of final quark-antiquark states. The new input parameters will be now those hadronic quantities that are measured on $Z$ resonance (hadronic widths and asymmetries, plus the strong coupling $\alpha_s(M_Z)$). Again, the use of these inputs will allow to express the remaining one loop theoretical expression in terms of subtracted quantities, that will be the three universal corrections $\Delta\alpha$, $R$ and $V$ already met for the leptonic case and new, non universal terms whose theoretical expression will be given for a number of potentially interesting experimental quantities. This will be done in full detail in the nextcoming Section 2. In the following Sections, we shall try to show that the same remarkable features exhibited by our representation for final leptonic states survive when one moves to hadronic states. With this aim, we shall consider in Section 3 an example of ”universal” effects of a model with anomalous gauge couplings, showing that our method would help to solve the problem of ”parameters excess” for this case. We shall also illustrate how the possible experimental visible signatures of this model would differ from those of another universal model of Technicolour type. In Section 4, we shall consider the example of ”non universal” effects of a model with one extra $Z$ of the most general nature, and show that it can be formally treated as a special case of our approach. We shall compare the effects of these models on a number of observables and show that it is possible to select a special set of three measurements that, in case a certain ”signal” were observed, would be able to indicate to which of the models it did belong. In Section 5 a final discussion will show that for all the new input parameters, the already available LEP1, SLC accuracy is sufficient to avoid the generation of sensible uncertainties in the theoretical predictions at the expected future experimental conditions. This will then conclude our work.

### 2 Derivation of the theoretical expressions

#### a) General case

The relevant quantity in our description will be the scattering amplitude for the four-fermion process $e^+e^- \rightarrow f\bar{f}$ at variable c.m. energy $\sqrt{q^2}$. A very convenient way of writing it at the considered one loop level has been shown in ref.[9] for the simplified
case $f = l$. In this more general paper we shall begin therefore by rewriting the needed expression, that reads:

$$A_{lf}^{(1)}(q^2, \theta) = A_{lf}^{(1)}(q^2, \theta) + A_{lf}^{Z(1)}(q^2, \theta) + "QED" + "QCD"$$

(1)

with the photon exchange term

$$A_{lf}^{\gamma(1)}(q^2, \theta) = A_{lf}^{\gamma(0)}(q^2, \theta)[1 - \tilde{F}_\gamma^{(lf)}(q^2, \theta)]$$

(2)

$$A_{lf}^{\gamma(0)}(q^2, \theta) = \frac{i}{q^2 - M^2_{Z0}} \left(\frac{g_0^2}{4\alpha_0}\right) \int \gamma^\mu u_\mu u_f \gamma^\nu v_f$$

(3)

where

$$g_{V l}^{(1)} = g_{V l}^{(0)} - 2s_1 c_1 Q_l F_{\gamma Z}^{(lf)}(q^2, \theta)$$

(5)

$$g_{V f}^{(1)} = g_{V f}^{(0)} - 2s_1 c_1 Q_f F_{\gamma Z}^{(lf)}(q^2, \theta)$$

(6)

with $s_1^2 = 1 - c_1^2$ and $s_2^2 c_1^2 = \frac{\alpha}{\sqrt{2} \alpha_0 M^2_{Z0}}$

Note that in the above equations bare couplings $g_0 = e_0/s_0$; $g_{Ah,f}^{(0)} \equiv I_{Ah,f}^{3L}$; $g_{Vh,f}^{(0)} \equiv I_{Vh,f}^{3L} - 2Q_{Ah,f}s_0^2$ and the bare Z mass $M_{Z0}$ are still contained.

The definition of the "generalized" one loop corrections, that are gauge invariant combinations of self-energies, vertices and boxes belonging to the independent Lorentz structures of the process (for a full and rigorous discussion about the choice of gauge-invariant combinations, we defer to previous papers by Degrassi and Sirlin [11], to whose conclusions and notations we shall try to stick as much as possible here) is the following:

$$\tilde{F}_\gamma^{(lf)}(q^2, \theta) = F_{\gamma}(q^2) - (\Gamma^{(\gamma)}_{\mu,l}, v_{\mu,l}^{(\gamma)}) - (\Gamma^{(\gamma)}_{\mu,f}, v_{\mu,f}^{(\gamma)}) + A_{\gamma,lf}^{(B)}(q^2, \theta)$$

(7)

$$A_{Z}^{(lf)}(q^2, \theta) = A_{Z}(q^2) - (q^2 - M^2_{Z})[\Gamma^{(Z)}_{\mu,l}, v_{\mu,l}^{(Z)}] + (\Gamma^{(Z)}_{\mu,f}, v_{\mu,f}^{(Z)}) + A_{Z,lf}^{(B)}(q^2, \theta)$$

(8)

$$\tilde{F}_{\gamma Z}^{(lf)}(q^2, \theta) = \frac{A_{\gamma Z}^{(lf)}(q^2, \theta)}{q^2}$$

(9)
\[ F_{\gamma Z}(q^2, \theta) \equiv \frac{A^{(lf)}_{\gamma Z}(q^2, \theta)}{q^2} \]
\[ = \frac{A_{\gamma Z}(q^2)}{q^2} - \frac{q^2 - M_Z^2}{q^2} \left[ (\Gamma_{\mu Z}^{(\gamma)}, v_{\mu Z}^{\gamma}) - (\Gamma_{\mu Z}^{(Z)}, v_{\mu Z}^{\gamma}) - (q^2 - M_Z^2)A_{\gamma Z,lf}(q^2, \theta) \right] \quad (10) \]

Here \( F_{\gamma}, A_{\gamma Z}, A_{\gamma Z} \) are the conventional self-energies, for which we shall follow the usual definition:
\[ A_i(q^2) \equiv A_i(0) + q^2 F_i(q^2) \quad (11) \]

(note that the physical \( Z \) mass \( M_Z \) now appears in eqs.(7)-(10)). The quantities denoted as \((\Gamma_{\mu Z}^{(\gamma)}, v_{\mu Z}^{\gamma})\) are the ”components” of the generalized \( l \) (or \( f \)) vertex along the photon, or \( Z \), Lorentz structure. For instance, we would write for the overall photon vertex correction to a fermion ”\( f \)”,
\[ \Gamma_{\mu f}^{(\gamma)} \equiv (\Gamma_{\mu f}^{(\gamma)}, v_{\mu f}^{\gamma}) + (\Gamma_{\mu f}^{(Z)}, v_{\mu f}^{Z}) \quad (12) \]

where
\[ v_{\mu f}^{\gamma} = e_0 Q_f \bar{u}_f \gamma_{\mu} v_f \quad (13) \]
\[ v_{\mu f}^{Z} = \frac{e_0}{2c_0 s_0} \bar{u}_f \gamma_{\mu}(g_{\nu f}^{(0)} - \gamma_5 g_{\nu f}^{(0)}) v_f \quad (14) \]

In our approach we shall need, rather than the previously defined ”generalized” corrections, the four ”subtracted” quantities defined as:
\[ \tilde{\Delta}^{(lf)}_{\alpha}(q^2, \theta) \equiv \tilde{F}^{(lf)}_{\gamma}(0, \theta) - \tilde{F}^{(lf)}_{\gamma}(q^2, \theta) \quad (15) \]
\[ R^{(lf)}(q^2, \theta) \equiv \tilde{I}^{(lf)}_{Z}(q^2, \theta) - \tilde{I}^{(lf)}_{Z}(M_Z^2, \theta) \quad (16) \]
\[ V_{\gamma Z}^{(lf)}(q^2, \theta) \equiv \tilde{F}_{\gamma Z}^{(lf)}(q^2, \theta) - \tilde{F}_{\gamma Z}^{(lf)}(M_Z^2, \theta) \quad (17) \]
\[ V_{Z\gamma}^{(lf)}(q^2, \theta) \equiv \tilde{F}_{Z\gamma}^{(lf)}(q^2, \theta) - \tilde{F}_{Z\gamma}^{(lf)}(M_Z^2, \theta) \quad (18) \]

where the ”auxiliary” quantity \( I_Z \) is defined as
\[ \tilde{I}^{(lf)}_{Z}(q^2, \theta) = \frac{q^2}{q^2 - M_Z^2} [\tilde{F}_{Z}(q^2, \theta) - \tilde{F}_{Z}(M_Z^2, \theta)] \quad (19) \]

In eq.(1) the ”pure QED” and the ”pure QCD” components can be tested separately and will not affect our research, which is only devoted to the investigation on new electroweak physics effects to the one-loop perturbative order.
After these (we hope not too long) introductory definitions, that we have given to make this paper as self-contained as possible, we are now in a position to derive our general expressions.

The simplest way to illustrate the philosophy of our procedure is that of showing the standard final form of the pure photonic contribution to the scattering amplitude. Using the conventional definition of the physical electric charge \( \alpha \equiv \alpha(0) \) one immediately realizes that:

\[
e_2^0 q^2 [1 - \tilde{F}_{\gamma}^{(lf)}(q^2, \theta)] \equiv \frac{4\pi\alpha}{q^2}[1 + \tilde{\Delta}^{(lf)}(q^2, \theta)] \tag{20}
\]

showing the known fact that the replacement of the bare charge by the physical charge, measured at \( q^2 = 0 \), is accompanied by the replacement of the "generalized" correction \( \tilde{F}_{\gamma}^{(lf)}(q^2) \) with the "photon-peak" subtracted quantity \( \tilde{F}_{\gamma}^{(lf)}(q^2) - \tilde{F}_{\gamma}^{(lf)}(0) \).

Our approach is based on a quite similar attitude for what concerns the "pure Z" and the "Z - \gamma interference" contributions. A typical quantity to be considered corresponds e.g. in our conventions to the term:

\[
\frac{ig_0^2}{4c_0^2} \frac{1}{q^2 - M_{Z0}^2} [1 - \frac{A_{Z}^{(lf)}(q^2, \theta)}{q^2 - M_{Z0}^2}] \tag{21}
\]

Using the tree level identity

\[
\frac{g_0^2}{4c_0^2} = \sqrt{2}G_{\mu,0}M_{Z,0} \tag{22}
\]

one immediately realizes that the term eq.(21) becomes exactly:

\[
\frac{g_0^2}{4c_0^2} \frac{1}{q^2 - M_{Z0}^2} [1 - \frac{A_{Z}^{(lf)}(q^2, \theta)}{q^2 - M_{Z0}^2}] \equiv \frac{\sqrt{2}G_{\mu}M_{Z}}{q^2 - M_{Z}^2 + iM_{Z}\Gamma_{Z}} [1 + \frac{\delta G_{\mu}}{G_{\mu}} + Re \frac{A_{Z}^{(lf)}(0, \theta)}{M_{Z}^2} - \tilde{I}_{Z}^{(lf)}(q^2, \theta)] \tag{23}
\]

(with the conventional definition of \( \Gamma_{Z} \)).

In eq.(23) the physical input is represented by \( M_{Z} \) and \( G_{\mu} \), with a certain "generalized" correction. Our approach consists, essentially, in rewriting this term (and other, similar, ones) by adding and subtracting \( \tilde{I}_{Z}(M_{Z}^2, \theta) \). In the specific case of eq.(23), this generates the quantity

\[
G_{\mu} [1 + \frac{\delta G_{\mu}}{G_{\mu}} + Re \frac{A_{Z}^{(lf)}(0, \theta)}{M_{Z}^2} - \tilde{I}_{Z}^{(lf)}(M_{Z}^2, \theta) - \tilde{I}_{Z}^{(lf)}(q^2, \theta) + \tilde{I}_{Z}^{(lf)}(M_{Z}^2, \theta)]
\]

\[
= G_{\mu} [1 + \epsilon_{1}^{(lf)}] [1 - R^{(lf)}(q^2, \theta)] \tag{24}
\]

where \( R^{(lf)}(q^2, \theta) \) is the "Z-peak" subtracted correction defined by eq.(16) and
\[ \epsilon_1^{(lf)} = \epsilon_1 + \left[ \Gamma_{\mu,f}^{(Z)}(\nu_{\mu,f}^{(Z)}) - (\Gamma_{\mu,l}^{(Z)}(\nu_{\mu,l}^{(Z)}) \right] \] (25)

Here \( \epsilon_1 \) is the Altarelli-Barbieri parameter, directly related to the partial Z width into leptons:

\[ \Gamma_l = \left(\frac{\sqrt{2}G_\mu M_Z^2}{48\pi}\right)[1 + \epsilon_1][1 + \tilde{v}_l^2(M_Z^2)] \] (26)

where

\[ \tilde{v}_l \equiv 1 - 4s_l^2(M_Z^2) \] (27)

and \( s_l^2(M_Z^2) \) is the quantity measured at LEP1 and SLC. Although a few more steps are still required, one can already understand the final goal of our approach, i.e. that of "trading" \( G_\mu \) for some physical Z partial width, measured at Z-peak. At the same time, this procedure will replace the 'generalized' corrections \( \tilde{I}_Z^{(lf)}(q^2) \) (and, also, \( \tilde{F}_{\gamma Z}^{(lf)}(q^2, \theta) \)) with the "Z-peak subtracted" quantities \( R^{(lf)}(q^2, \theta), V_{\gamma Z}^{(lf)}(q^2, \theta), V_{Z\gamma}^{(lf)}(q^2, \theta) \) defined by eqs.(16)-(18).

To fully understand the "replacement" mechanism, we shall now write the complete one-loop expression of a representative observable, chosen to be \( \sigma_{lf}(q^2) \), the cross section for production of a final \( f\bar{f} \) state. This can be done rather easily if one writes the tree-level expression of this quantity, that reads:

\[ \sigma_{lf}^{(0)}(q^2) = N_f \left(\frac{4\pi q^2}{3}\right) \left\{ \frac{\alpha_0^2 Q_l^2 Q_f^2}{q^4} + \frac{\sqrt{2}G_\mu^0 M_{Z0}^2}{4\pi} (g_{Vl}^{(0)} g_{Vf}^{(0)} + g_{Al}^{(0)} g_{Af}^{(0)}) \right\} \] (28)

\( (N_f = 3 \text{ for quarks}). \)

The corresponding expression at one loop is written immediately if one uses our starting eq.(1) and makes the simple and obvious replacements. One then easily derives:

\[ \sigma_{lf}^{(1)}(q^2) = \sigma_{lf}^{(0)}(q^2) + \sigma_{lf}^{(Z)}(q^2) + \sigma_{lf}^{(Z)}(q^2) = "QED" + "QCD" \] (29)

and finds for the "pure" Z exchange term:

\[ \sigma_{lf}^{(Z)}(q^2) = N_f \left(\frac{4\pi q^2}{3}\right) \left(\frac{\sqrt{2}G_\mu M_{Z0}^2}{16\pi}\right)^2 \left(\frac{1}{q^2 - M_{Z0}^2 + M_0^2 \Gamma_Z^2}\right)[1 + 2\epsilon_1^{(lf)}][1 + \tilde{v}_l^2][1 + \tilde{v}_f^2] \]

\[ [1 - 2\tilde{I}_Z^{(lf)}(q^2, \theta) - 8s_l c_l \left\{ \frac{v_l}{1 + v_l^2} V_{\gamma Z}^{(lf)}(q^2) + \frac{v_f |Q_f|}{1 + v_f^2} V_{Z\gamma}^{(lf)}(q^2) \right\}] \] (30)

6
where \( v_1, v_f \) are defined as

\[
v_{1,f} = 1 - 4|Q_{l,f}|s_1^2
\]

and \( s_1^2 = 0.212 \) is defined after eqs.(2),(3).

We also define the quantity (not to be confused with the one above)

\[
\tilde{v}_f = 1 - 4|Q_f|s_f^2(M_Z^2)
\]

with

\[
s_f^2(M_Z^2) \equiv s_1^2 + s_1c_1\tilde{F}^{(f)}_Z(M_Z^2)
\]

From eq.(30) one recovers the result of ref.[9] when \( f = l \). In that case, \( v_1 = v_f, \)
\( \epsilon_{1,f} = \epsilon_1, \) \( F_{\gamma Z} = F_{Z\gamma} \) and in the ”leading” terms \( (G_{\mu})^2 \) has been exactly replaced by the quantity \( \frac{\Gamma(M_Z^2)}{M_Z^2} \) (multiplied by a \( c \)-number), while in the correction the ”Z-peak subtracted” quantities \( R \equiv R^{ll} \) and \( V \equiv V_{\gamma Z}^{ll} \equiv V_{Z\gamma}^{ll} \) appear.

When \( l \neq f \), a very similar situation can be reproduced. One only has to introduce the quantity:

\[
\epsilon_1^{ff} = \epsilon_1 + 2\left[\frac{\epsilon^{(Z)}_{\mu,f}(v_{\gamma,f}^{(Z)})}{\Gamma_{\mu,f}} - \frac{\epsilon^{(Z)}_{\mu,l}(v_{\gamma,l}^{(Z)})}{\Gamma_{\mu,l}}\right]
\]

This is exactly related to the partial width of \( Z \) into \( f \bar{f} \) by the following expression

\[
\Gamma_f = N_f^{QCD} \left(\frac{\sqrt{2}G_{\mu}M_Z^2}{48\pi}\right)[1 + \epsilon_1^{ff}][1 + \tilde{v}_f^2(M_Z^2)]
\]

where

\[
N_f^{QCD} \approx 1 + \frac{\alpha_s(M_Z^2)}{\pi}
\]

The final observation is now the exact equality:

\[
2\epsilon_1^{(ff)} = \epsilon_1 + \epsilon_1^{(ff)}
\]

From this equality and from the previous formulae one is then finally led to the relevant expression:

\[
\sigma_{1f}^{(Z)}(q^2) = N_f\left(\frac{4\pi q^2}{3}\right)\left[\frac{3\Gamma_{l,l}^{(Z)}}{M_Z^2} + \frac{3\Gamma_{l,l}^{(Z)}}{N_fM_Z^2}\right][1 - 2R^{(ff)}(q^2)]
\]

\[
-8s_1c_1\left\{\frac{v_1}{1 + v_1}V_{\gamma Z}^{(ff)}(q^2) + \frac{v_f|Q_f|}{1 + v_f^2}V_{Z\gamma}^{(ff)}(q^2)\right\}
\]

Eq.(38) is one of the main results of this paper. It shows that the replacement of \( G_{\mu} \),
and the corresponding introduction of ”Z-peak subtracted” corrections, can be continued
to final hadronic states by introduction of quantities that correspond to those encountered in the leptonic case. Typically, $\sigma_{lf}$ will contain $\Gamma_l$ and $\Gamma_f$, as one would have naively expected, and the strong coupling $\alpha_s(M_Z^2)$ generated by eq.(35), that only affects the expression if $l \neq f$ and should not be considered as a ”QCD” correction in the notation of eq.(1). Note that only quantities that can be exactly defined and (in principle) measured on $Z$ resonance have been used to build our ”$Z$-peak modified Born approximation”.

The procedure that we have illustrated can now be repeated for the remaining components of $\sigma_{lf}$ (as well as for the other observables). In fact, there is no need of any trick for the ”pure $\gamma$” component, that remains given by the expression:

$$\sigma_{lf}^{(\gamma)}(q^2) = N_f(\frac{4\pi q^2}{3})Q_l^2 Q_f^2 \alpha_s(0) \frac{q^2 - M_Z^2}{q^2(q^2 - M_Z^2)^2 + M_Z^2 \Gamma_Z^2} \{1 + \frac{3\Gamma_l}{M_Z} + \frac{3\Gamma_f}{N_f M_Z}\} \frac{1}{1/2}$$

The ”$\gamma - Z$” interference can be treated in a straightforward way. To avoid writing too many formulae, we only give here the relevant final expression, that can be easily derived using the previously illustrated procedure:

$$\sigma_{lf}^{(\gamma Z)}(q^2) = N_f(\frac{4\pi q^2}{3})2\alpha(0)|Q_f| \frac{q^2 - M_Z^2}{q^2(q^2 - M_Z^2)^2 + M_Z^2 \Gamma_Z^2} \frac{3\Gamma_l}{M_Z} \frac{3\Gamma_f}{N_f M_Z} \frac{1}{1/2}$$

$$\tilde{v}_l \tilde{v}_f \frac{1}{(1 + \tilde{v}_f^2)^{1/2}(1 + \tilde{v}_f^2)^{1/2}} \{1 + \tilde{\Delta}(l f) \alpha(q^2) - R(l f)(q^2) \}$$

$$+ 4s_1 c_1 \{\frac{1}{v_l} V_{\gamma Z}^{l l}(q^2) + \frac{|Q_f|}{v_f} V_{\gamma Z}^{l l}(q^2)\}\}$$

Note that, besides $\Gamma_l$ and $\Gamma_f$, this expression contains the two parameters $s_l^2(M_Z^2)$ and $s_f^2(M_Z^2)$ (or $\tilde{v}_l$ and $\tilde{v}_f$) defined in eqs.(27), (32), (33), that are now not reabsorbed into $\Gamma_l$, $\Gamma_f$ as in the previous ”pure $Z$” term. This does not represent a problem since $s_l^2(M_Z^2)$ is the quantity measured at LEP1, SLC. The remaining parameter $s_f^2(M_Z^2)$ is also related to measured (or measurable) quantities at $Z$-peak, more precisely to forward-backward unpolarized asymmetries for $b$ and $c$ (already given by LEP1) and also, more directly, to the polarized forward-backward asymmetries for $b$ and $c$, called $A_{b,c}$ in the original proposal [1], to be measured at SLC in the near future [13]. In particular, in terms of $A_{b,c}$ we would have

$$A_{b,c} = \frac{2\tilde{v}_{b,c}}{1 + \tilde{v}_{b,c}^2}$$

(the unpolarized asymmetries are essentially given by the product of eq.(41) with the corresponding leptonic quantity that contains $s_l^2(M_Z^2)$). In conclusion, also in the case of $\sigma^{\gamma Z}$, the new complete ”Born” expression can be given in terms of quantities measured on $Z$ resonance. As we shall show in the final discussion, this will never introduce a relevant ”input” uncertainty in the obtained predictions.

To conclude this general part of Section 2, we still need the derivation of the quantity that appears in the numerator of an unpolarized forward-backward asymmetry. We shall write this observable in the following way:
\[ A_{FB,f}(q^2) = \frac{3\sigma_{FB,f}(q^2)}{4\sigma_f(q^2)} \]  

(42)

where \( \sigma_f \) has been previously defined. From the expression (that we do not write explicitly) of \( \sigma_{FB,f} \) at tree level it is immediate to derive, without introducing any other prescription or definition, the final relevant expression:

\[ \sigma_{FB,f}(q^2) \equiv \sigma_{FB,f}^{(Z)}(q^2) + \sigma_{FB,f}^{(\gamma Z)}(q^2) \]  

(43)

where:

\[ \sigma_{FB,f}^{(Z)}(q^2) = N_f \left( \frac{4\pi q^2}{3} \right) \frac{[\gamma \gamma_f]}{[M_f N_f]} \left( \frac{q^2 - M_Z^2}{2 + M_Z^2 \Gamma_Z^2} \right) \frac{4\bar{v}_l \bar{v}_f}{(1 + \bar{v}_l^2)(1 + \bar{v}_f^2)} \left[ 1 - 2R_{(f)}(q^2) - 4s_1c_1 \left\{ \frac{1}{v_l} V_{\gamma Z}^{(lf)}(q^2) + \frac{|Q_f|}{v_f} V_{Z \gamma}^{(lf)}(q^2) \right\} \right] \]  

(44)

and

\[ \sigma_{FB,f}^{(\gamma Z)}(q^2) = N_f \left( \frac{4\pi q^2}{3} \right) 2\alpha(0) |Q_f| \frac{q^2 - M_Z^2}{(q^2 - M_Z^2)^2 + M_Z^2 \Gamma_Z^2} \frac{3\Gamma_l \Gamma_f}{M_Z^{1/2} N_f M_f^{1/2}} \frac{1}{(1 + \bar{v}_l^2)^{1/2}(1 + \bar{v}_f^2)^{1/2}} \left[ 1 + \Delta_{\gamma Z}^{(lf)}(q^2) - R_{(f)}(q^2) \right] \]  

(45)

Eqs.(44) and (45) conclude our general technical introduction. We shall now consider in the next subsection 2b the explicit cases of experimental observables that will, or should, be measured in the very near future at LEP2 and, possibly, in a not too near future at NLC.

2b) Application to specific observables

To begin our analysis, we consider the simplest case that might realistically occur, i.e. that of the measurement of the cross section for \( b \bar{b} \) production, \( \sigma_{bb} \). Actually, we should rather consider the (experimentally more accurate) ratio \( R_{bb} = \sigma_{bb}/\sigma_{ll} \). Since the theoretical expression of \( \sigma_{ll} \) has been already given in ref.[9], we shall limit ourselves to deriving and discussing in detail the full expression of the numerator. Then in Sections 3 and 4 we shall rather use the ratio, whose expression can be easily derived.

When writing the full expression of \( \sigma_{bb} \), as well as that of the next considered observables, it will be very useful to separate the "universal" contributions of new physics from the "non universal" ones, that depend on properties of the final state that are different from the corresponding ones for leptons (e.g. specific non SM couplings, or masses). Clearly, the full set of self-energies contributions will belong to the first universal class, while boxes will generally produce non universal effects. For vertices, one can have both cases, as we shall show in the next sections.
After these premises, we can now write the complete expression

\[ \sigma_{ib}(q^2) = \sigma_{ib}^{(\gamma)}(q^2) + \sigma_{ib}^{(Z)}(q^2) + \sigma_{ib}^{(\gamma Z)}(q^2) \]  

(46)

where the three components are given by eqs.(39),(44),(45) and, following our previous discussion, we shall express the subtracted corrections in the form:

\[ \tilde{\Delta}^{(lb)} \alpha(q^2) = \tilde{\Delta} \alpha(q^2) + \delta \tilde{\Delta}^{(lb)} \alpha(q^2) \]  

(47)

\[ R^{(lb)}(q^2) = R(q^2) + \delta R^{(lb)}(q^2) \]  

(48)

\[ V_{\gamma Z}^{(lb)}(q^2) = V(q^2) + \delta V_{\gamma Z}^{(lb)}(q^2) \]  

(49)

\[ V_{Z\gamma}^{(lb)}(q^2) = V(q^2) + \delta V_{Z\gamma}^{(lb)}(q^2) \]  

(50)

where the quantities without indices are the universal ones that would appear in the case of final leptonic states treated in and:

\[ \delta \tilde{\Delta}^{(lb)} \alpha(q^2) = (\Gamma_{\mu,l}^{(\gamma)}(0), v_{\mu,l}^{(\gamma)}) - (\Gamma_{\mu,b}^{(\gamma)}(0), v_{\mu,b}^{(\gamma)}) - [(\Gamma_{\mu,l}^{(\gamma)}(M_Z^2), v_{\mu,l}^{(\gamma)}) - (\Gamma_{\mu,b}^{(\gamma)}(M_Z^2), v_{\mu,b}^{(\gamma)})] 
+ A_{\gamma,l,l}^{(B)}(q^2, \theta) - A_{\gamma,b}^{(B)}(q^2, \theta) \]  

(51)

\[ \delta R^{(lb)}(q^2) = Re\{(\Gamma_{\mu,l}^{(Z)}(0), v_{\mu,l}^{(Z)}) - (\Gamma_{\mu,b}^{(Z)}(0), v_{\mu,b}^{(Z)}) - [(\Gamma_{\mu,l}^{(Z)}(M_Z^2), v_{\mu,l}^{(Z)}) - (\Gamma_{\mu,b}^{(Z)}(M_Z^2), v_{\mu,b}^{(Z)})] 
+ A_{Z,l,l}^{(B)}(q^2, \theta) - A_{Z,b}^{(B)}(q^2, \theta)\} \]  

(52)

\[ \delta V_{\gamma Z}^{(lb)}(q^2) = \frac{q^2 - M_Z^2}{q^2} \text{Re}[(\Gamma_{\mu,b}^{(\gamma)}(q^2), v_{\mu,b}^{(\gamma)}) - (\Gamma_{\mu,l}^{(\gamma)}(q^2), v_{\mu,l}^{(\gamma)})] 
+ (q^2 - M_Z^2) \text{Re}[A_{\gamma,Z,l,l}^{(B)}(q^2, \theta) - A_{\gamma,Z,b}^{(B)}(q^2, \theta)] \]  

(53)

\[ \delta V_{Z\gamma}^{(lb)}(q^2) = \text{Re}\{(\Gamma_{\mu,l}^{(Z)}(q^2), v_{\mu,l}^{(Z)}) - (\Gamma_{\mu,b}^{(Z)}(q^2), v_{\mu,b}^{(Z)}) - [(\Gamma_{\mu,l}^{(Z)}(M_Z^2), v_{\mu,l}^{(Z)}) - (\Gamma_{\mu,b}^{(Z)}(M_Z^2), v_{\mu,b}^{(Z)})] 
+ (q^2 - M_Z^2)[A_{Z\gamma,Z,l,l}^{(B)}(q^2, \theta) - A_{Z\gamma,Z,b}^{(B)}(q^2, \theta)]\} \]  

(54)

Note that by definition \( A_{\gamma,l,f}^{(B)}(0, \theta) \) and \( A_{Z,l,f}^{(B)}(M_Z^2, \theta) \) identically vanish.

The previous expressions and definitions can be easily generalized to the case of the full final hadronic cross section, whose experimental measurement will be statistically favoured. After some additions and recombinations we are led to a first general expression that would read:

\[ \sigma_5(q^2) \equiv \sigma_{\text{had}}(q^2) = \sigma_{5}^{(\gamma)}(q^2) + \sigma_{5}^{(Z)}(q^2) + \sigma_{5}^{(\gamma Z)}(q^2) \]  

(55)
where

\[
\sigma_5^{(\gamma)}(q^2) = N \left( \frac{4\pi q^2}{3} \right) \left( \frac{11\alpha^2(0)}{9q^4} \right) [1 + \delta_5^{(\gamma)}]
\]  

(56)

\[
\delta_5^{(\gamma)} = 2\tilde{\Delta}^{(u)}(q^2) + \frac{16}{11} \tilde{\Delta}^{(iu)}(q^2) + \frac{4}{11} \tilde{\Delta}^{(id)}(q^2) + \frac{2}{11} \tilde{\Delta}^{(id)}(q^2)
\]  

(57)

where following the attitude explained at the beginning of Section 2a, we set \( N = 3 \). For the next term \( \sigma_5^{(Z)} \) we find, after a number of elementary steps

\[
\sigma_5^{(Z)}(q^2) = N \frac{4\pi q^2}{3} \frac{[3\Gamma_q M_Z^5][3\Gamma_5 q^2]}{[N_f M_Z^5]} \left[ 1 + \delta_5^{(Z)} \right]
\]  

(58)

where \( \Gamma_5 = \Gamma_{had} \) and

\[
\delta_5^{(Z)} = -2R(q^2) - 4s_1 c_1 p_5 V(q^2)
\]

\[
-\frac{2\Gamma_u}{\Gamma_5} [2\delta R^{(lu)}(q^2) + \frac{8s_1 c_1 v_1}{1 + v_1^2} \delta V^{(lu)}(q^2) + \frac{16s_1 c_1 v_u}{3(1 + v_u^2)} \delta Z^{(lu)}(q^2)]
\]

\[
-\frac{2\Gamma_d}{\Gamma_5} [2\delta R^{(ld)}(q^2) + \frac{8s_1 c_1 v_1}{1 + v_1^2} \delta V^{(ld)}(q^2) + \frac{8s_1 c_1 v_d}{3(1 + v_d^2)} \delta Z^{(ld)}(q^2)]
\]

\[
-\frac{\Gamma_b}{\Gamma_5} [2\delta R^{(lb)}(q^2) + \frac{8s_1 c_1 v_1}{1 + v_1^2} \delta V^{(lb)}(q^2) + \frac{8s_1 c_1 v_b}{3(1 + v_b^2)} \delta Z^{(lb)}(q^2)]
\]  

(59)

with

\[
p_5 = \frac{v_1}{1 + v_1^2} + \frac{4\Gamma_u}{3\Gamma_5} \frac{v_u}{1 + v_u^2} + \frac{2\Gamma_d}{3\Gamma_5} \frac{v_d}{1 + v_d^2} + \frac{\Gamma_b}{3\Gamma_5} \frac{v_b}{1 + v_b^2}
\]  

(60)

From a glance at eq.(59), one might have the impression that both in the "universal" and in the "non universal" component of the corrections a number of unwanted (i.e. not directly measured on Z resonance) ratios \( \Gamma_q/\Gamma_5 \) appear. But this is not a problem at the considered one-loop level since these terms are already multiplied by order \( \alpha \). Therefore, they must be consistently replaced by expressions that only involve the quantity \( s_1^2 \) entering eq.(33) (note that \( \epsilon_{1}^{eff} \) can be neglected for the same reasons). As a consequence we can write in eq.(59)

\[
\frac{\Gamma_{u,c}}{\Gamma_5} = \frac{1 + v_u^2}{2(1 + v_u^2) + 3(1 + v_u^2)}
\]  

(61)

\[
\frac{\Gamma_{d,s,b}}{\Gamma_5} = \frac{1 + v_d^2}{2(1 + v_d^2) + 3(1 + v_d^2)}
\]  

(62)

The same considerations and simplifications strictly valid at one loop can be repeated for the interference component. After some straightforward rearrangements, this leads to the expression:

\[
\frac{\Gamma_{u,c}}{\Gamma_5} = \frac{1 + v_u^2}{2(1 + v_u^2) + 3(1 + v_u^2)}
\]  

(61)

\[
\frac{\Gamma_{d,s,b}}{\Gamma_5} = \frac{1 + v_d^2}{2(1 + v_d^2) + 3(1 + v_d^2)}
\]  

(62)
\[ \sigma^{(\gamma Z)}_5(q^2) = N \frac{4\pi q^2}{3} 2\alpha(0) |Q_b| \frac{q^2 - M_Z^2}{q^2(q^2 - M_Z^2)^2 + M_Z^2 \Gamma_Z^2} \]

\[ \left[ \frac{3\Gamma_f}{M_Z} \right]^{1/2} \Sigma_5 \frac{\bar{v}_t}{(1 + \bar{v}_t^2)^{1/2}} [1 + \delta^{(\gamma Z)}] \]  

\[ \delta^{(\gamma Z)} = \tilde{\Delta} \alpha(q^2) - R - 4s_1c_1p'_b V \]

\[ + \frac{4}{\Sigma_5} \left( \frac{3N_a \Gamma_u}{M_Z} \right)^{1/2} \frac{v_u}{(1 + v_u^2)^{1/2}} [\delta \tilde{\Delta}^{(tu)} \alpha(q^2) - \delta R^{(tu)}(q^2) - \frac{4s_1c_1}{v_1} \delta V^{(tu)}_{\gamma Z}(q^2) - \frac{8s_1c_1}{3v_u} \delta V^{(tu)}_{\gamma Z}(q^2)] \]

\[ + \frac{2}{\Sigma_5} \left( \frac{3N_a \Gamma_d}{M_Z} \right)^{1/2} \frac{v_d}{(1 + v_d^2)^{1/2}} [\delta \tilde{\Delta}^{(td)} \alpha(q^2) - \delta R^{(td)}(q^2) - \frac{4s_1c_1}{v_1} \delta V^{(td)}_{\gamma Z}(q^2) - \frac{8s_1c_1}{3v_d} \delta V^{(td)}_{\gamma Z}(q^2)] \]

\[ + \frac{1}{\Sigma_5} \left( \frac{3N_b \Gamma_b}{M_Z} \right)^{1/2} \frac{v_b}{(1 + v_b^2)^{1/2}} [\delta \tilde{\Delta}^{(tb)} \alpha(q^2) - \delta R^{(tb)}(q^2) - \frac{4s_1c_1}{v_1} \delta V^{(tb)}_{\gamma Z}(q^2) - \frac{8s_1c_1}{3v_b} \delta V^{(tb)}_{\gamma Z}(q^2)] \]

with

\[ \Sigma_5 = 4 \left( \frac{3N_a \Gamma_u}{M_Z} \right)^{1/2} \frac{\bar{v}_u}{(1 + \bar{v}_u^2)^{1/2}} + \left( \frac{3N_a \Gamma_d}{M_Z} \right)^{1/2} \frac{\bar{v}_d}{(1 + \bar{v}_d^2)^{1/2}} + \left( \frac{3N_b \Gamma_b}{M_Z} \right)^{1/2} \frac{\bar{v}_b}{(1 + \bar{v}_b^2)^{1/2}} \]

\[ p'_b = \frac{1}{v_1} + \frac{8}{3(1 + v_u^2)^{1/2} \Sigma_5} \left( \frac{3N_a \Gamma_u}{M_Z} \right)^{1/2} + \frac{2}{3(1 + v_d^2)^{1/2} \Sigma_5} \left( \frac{3N_a \Gamma_d}{M_Z} \right)^{1/2} + \frac{1}{3(1 + v_b^2)^{1/2} \Sigma_5} \left( \frac{3N_b \Gamma_b}{M_Z} \right)^{1/2} \]

and \( N_{u,d,b} = 3 \).

Similarly to the case of eq.(61),(62), the quantities \( \Gamma_f^{1/2}/\Sigma_5 \) can be safely evaluated in terms of \( s_1^2 \) only. The quantity \( \Sigma_5 \) eq.(65) requires a separate discussion, that will be given in the concluding remarks, to show that it can be safely neglected (or approximated).

To conclude our review, we still have to consider the separation of the quantities eq.(44),(45) that give the numerator of the forward-backward asymmetry for \( bb \) production. This can be done in the way that we have illustrated, and leads to the expressions

\[ \sigma^{(\gamma Z)}_{FB,ib}(q^2) = N \frac{4\pi q^2}{3} 2\alpha(0) |Q_b| \frac{q^2 - M_Z^2}{(q^2 - M_Z^2)^2 + M_Z^2 \Gamma_Z^2} \]

\[ \left[ \frac{3\Gamma_f}{M_Z} \right]^{1/2} \left[ \frac{3\Gamma_b}{N_b M_Z} \right]^{1/2} \frac{1}{(1 + \bar{v}_t^2)^{1/2}(1 + \bar{v}_b^2)^{1/2}} [1 + \tilde{\Delta} \alpha(q^2) - R(q^2) + \delta \tilde{\Delta}^{(tb)} \alpha(q^2) - \delta R^{(tb)}(q^2)] \]

\[ \sigma^{(\gamma Z)}_{FB,ib}(q^2) = N \frac{4\pi q^2}{3} \left[ \frac{3\Gamma_f}{M_Z} \right]^{1/2} \left[ \frac{3\Gamma_b}{N_b M_Z} \right]^{1/2} \frac{4\bar{v}_b \bar{v}_t}{(q^2 - M_Z^2)^2 + M_Z^2 \Gamma_Z^2} \]
\[ [1 - 2R(q^2) - 4s_1c_1 \frac{1}{v_1} + \frac{|Q_b|}{v_b}] V(q^2) \]
\[ -2 \delta R^{(lb)}(q^2) - 4s_1c_1 \left\{ \frac{1}{v_1} \delta V^{(lb)}_\gamma(q^2) + \frac{|Q_b|}{v_b} \delta V^{(lf)}_\gamma(q^2) \right\} \]

Eqs. (67), (68) conclude this long section. We are now in a position to calculate, using the leptonic formulae or ref. [9], the contributions of new physics of both universal and nonuniversal type to the full set of experimental quantities that will be measured at LEP2 and NLC (without the extra facility of longitudinal initial electron polarization in the latter case). In particular, we shall consider on top of the leptonic observables previously considered in ref. [9], i.e. $\sigma_\mu$, $A_{FB,\mu}$ and $A_\tau$ (the final $\tau$ polarization), the ratios:

\[ R_5 = \frac{\sigma_5}{\sigma_\mu} \]
\[ R_b = \frac{\sigma_{lb}}{\sigma_\mu} \]

and $A_{FB,b}$. The relevant expressions can be derived from Section 2 and from ref. [9]. We shall give them explicitly in the next Section 3 and 4 for two orthogonal situations of models with universal and nonuniversal type of effects.

3 A Model with AGC (Anomalous Gauge Couplings)

As a first example of application of our approach, we shall consider the case of a model of new physics in which Anomalous Gauge Couplings [7] are generated by an effective lagrangian. Although the discussion could be much more general, we shall first stick to the dimension six, CP conserving Lagrangian proposed by Hagiwara, S. Ishihara, R. Szalapski and D. Zeppenfeld [8]. This contains, in principle, eleven parameters of which nine would affect the $WWV$ couplings. In particular, the most general four fermion process at the one loop level would be affected by four ”renormalized” parameters denoted in ref. [8] as $f_{DW}^f$, $f_{DB}^f$, $f_{\phi 1}^f$ and $f_{BW}^f$ for $f \neq b$. If final $b\bar{b}$ production is considered, one should, in principle, include the order ($m_\tau^2$) contributions generated by $f_W$, $f_B$ that have been recently shown to appear in the partial width of $Z$ into $b\bar{b}$ [4].

The calculation of this type of effects has been already performed for the purely leptonic case in ref. [9]. The main feature that appears is that only two independent parameters i.e. $f_{DW}^l$, $f_{DB}^l$ survive in the full set of leptonic observables. This is due to the fact that in the contribution of the model to the subtracted corrections $\tilde{\Delta} \alpha$, $R$ and $V$ the terms proportional to $f_{\phi 1}$, $f_{BW}$, that carry no sufficient powers of $q^2$, are fully reabsorbed into the subtraction constant i.e. into the trading of $G_\mu$ by $\Gamma_1$ and $s_2^2(M_Z^2)$. This leads to the expressions:

\[ \tilde{\Delta}^{(AGC)} \alpha(q^2) = -q^2 \frac{2e^2}{A^2} (f_{DW}^l + f_{DB}^l) \]
\[ R^{(AGC)}(q^2) = (q^2 - M_Z^2) \left( \frac{2e^2}{s_1^1 c_1^1 \Lambda^2} \right) (f_{DW} c_1^4 + f_{DB}^r s_1^4) \] (72)

\[ V^{(AGC)}(q^2) = (q^2 - M_Z^2) \left( \frac{2e^2}{s_1^1 c_1^1 \Lambda^2} \right) (f_{DW} c_1^4 + f_{DB}^r s_1^4) \] (73)

We now perform the same calculation for \( R_5 \), \( R_b \) and \( A_{FB,b} \). In principle, we might expect the appearance of the extra parameters \( f_W, f_B \) in the expression of the final \( b \) contribution. In fact, the rigorous expression for \( R_5 \) would read (neglecting numerically irrelevant contributions):

\[ \frac{\delta R_5^{(AGC)}}{R_5} \simeq C_\alpha(q^2) \tilde{\Delta}^{(AGC)} \alpha(q^2) + C_R(q^2) R^{(AGC)}(q^2) + C_V(q^2) V^{(AGC)}(q^2) + C_b(q^2) \delta R_{lb}^{(AGC)}(q^2) \] (74)

and \( C_\alpha, C_R, C_V(q^2) \) are certain kinematical functions whose numerical value at the "reference" points \( q^2 = 4M_Z^2 \) (LEP2) and \( q^2 = (500 GeV)^2 \) are:

\[ C_\alpha(4M_Z^2) = -0.77 \quad C_\alpha((500 GeV)^2) = -0.67 \] (75)

\[ C_R(4M_Z^2) = -0.77 \quad C_R((500 GeV)^2) = -0.67 \] (76)

\[ C_V(4M_Z^2) = -0.81 \quad C_V((500 GeV)^2) = -0.75 \] (77)

The last term in eq.(77) contains a kinematical coefficient \( C_b \) such that

\[ C_b(4M_Z^2) = -0.25 \quad C_b((500 GeV)^2) = -0.20 \] (78)

and a "non universal" contribution, typical of the final \( Zb\bar{b} \) couplings. In terms of parameters of the model, one gets after a straightforward calculation whose main points have been illustrated in a previous reference [4]:

\[ \delta R_{lb}^{(AGC)} = 2 \left( \frac{q^2 - M_Z^2}{M_Z^2} \right) \left( \frac{\alpha m_t^2}{64\pi s_1^4 \Lambda^2} \right) (f_W - f_B s_1^2) \log \left( \frac{\Lambda^2}{M_Z^2} \right) \] (79)

In fact, in ref.[4] a bound for a different combination of \( f_W, f_B \) was calculated, assuming that the still conceivable small discrepancy between the experimental value of \( \Gamma_{b\bar{b}} \) at resonance and the SM prediction was originated by this type of new physics. From that calculation one sees however that, even pushing the bound to the extreme value, we would not affect the relative \( R_5 \) shift by more than a fraction of a percent, hardly visible at realistic experimental conditions. For this reason, and keeping in mind that the complete correction to \( R_5 \) contains in principle such non universal terms, we have in fact neglected them in the nextcoming considerations. This has the welcome consequence that another experimental variable can be added to the previous leptonic set without increasing the
overall number of parameters to be fitted, or bounded. More precisely, we would have now, at LEP2 energy:

\[ \frac{\delta R_5^{(AGC)}}{R_5} = 1.87\left(\frac{M^2_Z}{\Lambda^2}\right)f_{DW} + 0.68\left(\frac{M^2_Z}{\Lambda^2}\right)f_{DB} \]  

(80)

The previous considerations can be exactly repeated for \( R_b \). Leaving aside a more general discussion, we would find in this case in the configuration \( q^2 = 4M^2_Z \):

\[ \frac{\delta R_b^{(AGC)}}{R_b} = -1.13[\tilde{\Delta}^{(AGC)}(q^2) + R^{(AGC)}(q^2)] - 0.94V^{(AGC)}(q^2) - 1.53\delta R_b^{(AGC)}(q^2) \]  

(81)

Again, the conceivable contribution from the non universal term would be, at most, of a few (two-three) relative percent, that should be realistically below the observability limits. Neglecting again this contribution would lead us to the approximate expression:

\[ \frac{\delta R_b^{(AGC)}}{R_b} = -4.14\left(\frac{M^2_Z}{\Lambda^2}\right)f_{DW} - 1.26\left(\frac{M^2_Z}{\Lambda^2}\right)f_{DB} \]  

(82)

To conclude this illustration, we have calculated the contribution to the forward-backward \( b \)-asymmetry. This quantity, unlike the two previous cases, does not receive in practice appreciable contributions from the non universal part, which is essentially of left-handed type. The rigorous expression at LEP2 energies would therefore read:

\[ \frac{\delta A_{FB,b}^{(AGC)}}{A_{FB,b}} = 0.40[\tilde{\Delta}^{(AGC)}(q^2) + R^{(AGC)}(q^2)] - 0.42V^{(AGC)}(q^2) \]  

(83)

In conclusion, we have now at our disposal six experimental variables \((\sigma_\mu, A_{FB,\mu}, A_\tau, R_5, R_b, A_{FB,b})\) that only depend on two parameters (and that, at most, would contain one extra third combination of \( f_W \) and \( f_B \)). This represents, in our opinion, an interesting alternative to the conventional analyses [8], where the full set of six parameters should enter in the previous observables. In fact a rigorous calculation, that fully takes into account the effects of QED radiation, is at the moment being performed and will be shown in a separate dedicated paper. Here we can give a qualitative hint looking e.g. at the particular effect on \( R_5 \), eq.(64). In correspondence to a typical couple of values that would still be allowed [14] by the available low-energy constraints i.e. \( f_{DW} = -1, f_{DB} = 4 \), we would find a relative positive shift of approximately six percent in \( R_5 \), that would lead to a spectacular visible signal.

As a final byproduct of our approach, in which the number of parameters for this specific model is drastically reduced and in practice only two independent quantities remain, we shall obtain the (pleasant) result that, for any chosen triplet of observables, there will be a linear relationship between the separate effects that will correspond to a plane in the 3-dimensional space of the observables. Drawing these planes for various choices of variables is rather easy. Here we want to show two particular examples related
to the choices of \((\sigma_\mu, A_{FB,\mu}, A_r)\) and \((\sigma_\mu, A_{FB,\mu}, R_5)\) as "coordinate axes". The corresponding regions are shown in Figs.1,2 in the simple approximation that corresponds to our approximate equations (a more rigorous derivation, with a full QED convolution of effects, will be given, as we preannounced, in a forthcoming paper). To make a meaningful statement, we have shown in these Figures the "dead" region where a signal would not be distinguishable, corresponding to a relative experimental error of 1.5 percent for the various cross sections and forward-backward asymmetry and 15 percent for the tau polarization (these values assume an integrated luminosity of 500 \(pb^{-1}\) at \(\sqrt{q^2} = 2M_Z\), and correspond to a muon cross section of 4.4 \(pb\)). Therefore, if a signal of new physics were seen in some of the aforementioned observables, one would be able to decide whether the signal belongs to the considered model, or not. In fact, one might even hope to find a sort of one-to-one correspondence between models and regions of a certain 3-dimension space of observables.

Although we cannot prove this statement in general, we have found an encouraging manifestation of this possibility considering the case of a Technicolour-type model with a couple of strong vector resonances. The full details of this model have been already discussed in two previous references \[15\], \[9\], and we shall not repeat them here. The only thing that we will show are the characteristic regions of the model, that is essentially describable by two parameters. As one can see in Figs.1,2 the visible regions (where the size of the effect is larger than that of the realistic experimental error \[2\]) of the AGC and of the TC models are indeed well separated, and no confusion between these two models would possibly arise.

Having illustrated, we hope in a clear way, the main features of our approach for a specific type of (almost) universal new physics effects, we shall devote the next and last section to the discussion of a "typically" non universal kind of effects, generated by the presence of one extra (and of the most general type) \(Z\).

### 4 A Model with one General Extra \(Z\)

As a possibly rewarding unconventional application of our method, we illustrate the treatment of a model where one extra \(Z\) (generically denoted \(Z’\)), with the most general type of vector and axial couplings to leptons and quarks, is supposed to exist. All the popular "canonical" models (\(E_6\), \(LR\) symmetry, composite models,...) will be then recovered by adjusting the couplings to the corresponding values.

The effect of a heavy \(Z’\), of a mass not smaller than \(\simeq 400 - 500 GeV\), as suggested from the available CDF limits \[16\], is usually treated at "\(Z’\)-tree level" i.e. only adding to the full amplitude the graph with the \(Z’\) exchange, where both its couplings to fermions and its mass are identified with the physical ones. This leads to a modification of the Born amplitude of the following form:

\[
A_{lf}^{\gamma,Z,Z'} = A_{lf}^{\gamma,Z} + \frac{i}{q^2 - M_{Z'}^2} v_{\mu,l}^{(Z')}(Z') v_{\mu,f}^{(Z')}
\]  

(84)
with the general $Z' ff$ couplings

$$v_{\mu,f}^{(Z')} = \left( \frac{e}{2 c_1 s_1} \right) u_f \gamma_{\mu} (g_{V_f} - \gamma^5 g_{A_f}) v_f$$

From a formal point of view, that will be particularly suited for our approach, it is possible to rewrite the $Z'$ effect as a modification of our "generalized" subtracted corrections. This effect, that would correspond exactly to a "box-type" modification of completely non universal type, can be described in the following way:

$$\tilde{\Delta}^{(l,f)(Z')}_{\alpha}(q^2) = \frac{q^2}{q^2 - M_{Z'}^2} \left( \frac{1}{4 s_1^2 c_1^2} \right) \left( \frac{g_{V_l} g_{V_f}}{Q_l Q_f} \right) \left( (\xi_{V_l} - \xi_{A_l})(\xi_{V_f} - \xi_{A_f}) \right)$$

$$R^{(l,f)(Z')}_{\gamma}(q^2) = -\left( \frac{q^2 - M_{Z'}^2}{q^2 - M_{Z'}^2} \right) \xi_{A_l} \xi_{A_f}$$

$$V^{(l,f)(Z')}_{\gamma Z}(q^2) = -\left( \frac{q^2 - M_{Z'}^2}{q^2 - M_{Z'}^2} \right) \left( \frac{g_{V_f}}{2 s_1 c_1 Q_f} \right) \xi_{A_l} (\xi_{V_f} - \xi_{A_f})$$

where we have used the definitions:

$$\xi_{V,l,f} \equiv g_{V,l,f} g_{V,l,f}$$

$$\xi_{A,l,f} \equiv g_{A,l,f} g_{A,l,f}$$

$$g_{A,l,f} \equiv I_{l,f}^{3L}$$

$$g_{V,l,f} \equiv I_{l,f}^{3L} - 2 Q_l f s_1^2$$

One sees from eqs.(90)-(92) that the most general $Z'$ effect at $e^+e^-$ colliders is parametrizable via six independent effective couplings, that could be chosen as e.g. $\xi_{V,A,i} \sqrt{\frac{M_{Z'}}{M_{Z'}^2 - q^2}}$ ($i = l, u, d$). Therefore, with one experiment at fixed $q^2$ it would never be possible to disentangle $\xi_{V,A}$ from $M_{Z'}$, so that the normal attitude would be to derive (in case of negative searches) bounds for $M_{Z'}$ for given $\xi_{V,A}$. In fact, this will be done in another specific dedicated paper in preparation. Here we want to show that, in full analogy with the final example of the previous section, it would be possible to draw a region in a 3-dimensional space of observables that would be typical of the most general $Z'$. To achieve this goal, one must necessarily choose three purely leptonic observables.

At LEP2, this might be obtained by combining the measurements of $\sigma_{\mu}$ and $A_{FB,\mu}$ with that of the final $\tau$ polarization. At NLC, the role of the final $\tau$ polarization would be played by the (theoretically equivalent) longitudinal polarization asymmetry for leptons.
The general $Z'$ contribution to these quantities will actually take the form of eq. (71)-(73) with $\Delta^{(AGC)}_\alpha(q^2)$, $R^{(AGC)}(q^2)$, $V^{(AGC)}(q^2)$ respectively replaced by $\Delta^{(Z')}$, $R^{(Z')}(q^2)$ and $V^{(Z')}(q^2)$ given in eq. (93)-(95) for $f = l$.

Eliminating the two effective leptonic parameters gives then rise to a relationship between the shifts of $\sigma_\mu$, $A_{FB,\mu}$ and $A_\tau$ that would lead, at LEP2 energies, to a certain 3-dimensional region characteristic of this model and represented in Fig.3 (we assumed the same experimental errors as in the previous figures). Note that, with this procedures, all residual "intrinsic" $Z'$ ambiguities e.g. in the normalization of $g'_V$, $g'_A$ disappear.

A warning is necessary at this point since this Figure, as well as the previous ones, have been drawn in "first approximation" i.e. without calculating the fully QED convoluted effects (this is, in fact, in preparation at the moment). We can, though, claim that, as a general feature of such more realistic calculations, the "first approximation" results are quite reasonably reproduced provided that a suitable cut is enforced on the hard photon spectrum. In this spirit, we believe that it makes sense to compare Fig.3 for the $Z'$ model with the corresponding Fig.1 for the AGC and TC models and conclude that, at least in this orientative picture, the three regions corresponding to these theoretically "orthogonal" models are completely (i.e. in the physically reasonable region where a statistical meaning can be attributed to the signal) separated.

5 Concluding remarks

We have shown in this paper that the calculation of new physics effects in a general four-fermion process is facilitated if the procedure of "trading" $G_\mu$ by quantities measured on $Z$ peak is generalized from the case of final leptonic states to that of final hadronic states. The new relevant quantities that enter the modified Born Approximation are the $Z$ hadronic widths $\Gamma_5$ and $\Gamma_b$ and, to a much smaller extent the charm width $\Gamma_c$ and the two forward-backward asymmetries $A_{FB,c}$, $A_{FB,b}$ on $Z$ resonance, if we only consider the measurements of $\sigma_5$, $\sigma_b$ and $A_{FB,b}$ at variable $q^2$. We want to conclude this paper by making this statement more quantitative.

Consider $\sigma_5$ first. Here the leading terms at Born level are the pure photon and the pure $Z$ contributions. In our modified expression, the only Born term that changes is that corresponding to $Z$ exchange, whose numerical weight is roughly of the same size as that of the photon. The net effect of the change is that of replacing here $G^2_\mu$ by the product of $\Gamma_1$ and $\Gamma_5$. The corresponding relative experimental error thus introduced is a fraction of a percent \[\text{\%}\], much below the experimental reach at any future $e^+e^-$ collider. The same conclusion applies to the term $N_f = 3(1 + \frac{\alpha_s(M_Z^2)}{\pi})$ that divides $\Gamma_5$ and that generates an error of a few per mille at most. Note that the same relative error will affect the contribution that we called "QCD", since $\alpha_s(q^2)$ should be known with the same accuracy as $\alpha_s(M_Z^2)$. The remaining new input quantities that enter $\sigma_5$ are $\Gamma_c$ and $s^2_{b,c}(M_Z^2)$ defined by eq.(33). But even without discussing this point in full detail, as one could easily do, one sees immediately that these new parameters only contribute to the interference $\gamma - Z$. The latter is, already at the starting Born level, completely negligible.
with respect to the dominant pure photon and $Z$ ones. Therefore, a discussion on the effect of "small" changes in this term is, indeed, completely academic and we shall not give it here.

In the case of $\sigma_b$, the same situation is almost identically reproduced, with the only replacement of $\Gamma_5$ by $\Gamma_b$ in the $Z$ Born expression. The error on $\Gamma_b$ is in fact slightly larger, of a relative one percent [2], but also the experimental accuracy for $\sigma_b$ will be certainly larger than one percent, and the same conclusions as in the case of $\sigma_5$ still apply.

The last case to be discussed is that of $A_{FB,b}$. Here the situation is quite different since the $\gamma - Z$ term is now largely dominating. This term contains $\Gamma_l$, $\Gamma_b$, that will introduce errors of negligible size (i.e. at the relative level of less than one percent) and a term containing $s_b^2(M_Z^2)$ as one sees from eq.(67). In fact, the relevant quantity to be considered is

$$\frac{1}{(1 + \tilde{v}_b^2)^{1/2}}$$

(94)

that is directly related to the forward-backward asymmetry on $Z$ resonance $A_{FB,\phi}(M_Z^2)$ [3]. From the 4 percent uncertainty on this quantity given in ref. [3] one can derive the relative error on the term in eq.(94) that generates a 3 percent uncertainty on the prediction for $A_{FB,b}$. This is also weaker than the experimental uncertainty expected at LEP2.

In conclusion, all the replacements in the Born approximation are completely harmless for the considered process. Therefore, the gain that we obtained in the corresponding simplifications of the "subtracted" corrections seems to us rather remarkable. We would say that the full and rigorous exploitation of the high precision measurements of electroweak physics at $q^2 = M_Z^2$ allows to perform calculations of virtual new physics effects at LEP2 (and, possibly, at NLC) in a way that seems to us simpler and cleaner than the conventional one where $G_\mu$, the high precision electroweak measurement at $q^2 = 0$, is used. We are now in the process of applying the method to other possibly interesting models of new physics for which calculations of virtual effects might be relevant at future $e^+e^-$ colliders.
