The initial value problem for the Binormal Flow with rough data

SOCIÉTÉ MATHÉMATIQUE DE FRANCE
THE INITIAL VALUE PROBLEM FOR THE BINORMAL FLOW WITH ROUGH DATA

BY VALERIA BANICA AND LUIS VEGA

Abstract. – In this article we consider the initial value problem of the binormal flow with initial data given by curves that are regular except at one point where they have a corner. We prove that under suitable conditions on the initial data a unique regular solution exists for strictly positive and strictly negative times. Moreover, this solution satisfies a weak version of the equation for all times and can be seen as a perturbation of a suitably chosen self-similar solution. Conversely, we also prove that if at time $t = 1$ a small regular perturbation of a self-similar solution is taken as initial condition then there exists a unique solution that at time $t = 0$ is regular except at a point where it has a corner with the same angle as the one of the self-similar solution. This solution can be extended for negative times. The proof uses the full strength of the previous papers [9], [2], [3] and [4] on the study of small perturbations of self-similar solutions. A compactness argument is used to avoid the weighted conditions we needed in [4], as well as a more refined analysis of the asymptotic in time and in space of the tangent and normal vectors.

Résumé. – Dans cet article on considère le flot binormal avec données initiales des courbes régulières partout sauf en un point où elles ont un coin. On montre sous des conditions appropriées sur la donnée initiale qu’il existe une unique solution régulière pour des temps strictement positifs et négatifs. De plus, cette solution satisfait le flot binormal en un sens faible et peut être vue comme une perturbation d’une solution auto-similaire bien choisie. Réciproquement, on montre aussi que si à temps $t = 1$ on prend comme donnée initiale une petite perturbation régulière d’une solution auto-similaire, alors il existe une unique solution, qui à temps $t = 0$ est régulière partout sauf en un point où elle a un coin de même angle que celui formé par la solution auto-similaire. Cette solution peut être prolongée aux temps négatifs. La preuve s’appuie sur les résultats des articles précédents [9], [2], [3] et [4] sur l’étude des petites perturbations des solutions auto-similaires. Un argument de compacité est utilisé pour éviter les conditions à poids imposées dans [4], ainsi qu’une analyse plus raffinée des asymptotiques en temps et en espace des vecteurs tangents et normaux.
1. Introduction

We consider the binormal flow equation

\[ \chi_t = \chi_x \wedge \chi_{xx}, \]

which is a geometric law for the evolution in time of a curve \( \chi(t) \) in \( \mathbb{R}^3 \), parametrized by arc length \( x \). This model has been proposed in 1906 by Da Rios [7], and rediscovered in 1965 by Arms and Hama [1], as a model for the evolution of a vortex filament in a 3-D inhomogeneous inviscid fluid (see also [21], [20] for the history of this equation). It was also used as a model for vortex filament dynamics in superfluids ([16], [17], [5]). From (1) it follows that the tangent vector \( T(t, x) \) satisfies the Schrödinger map equation on the sphere \( S^2 \),

\[ T_t = T \wedge T_{xx}. \]

Also using the Frenet equations for the tangent \( T \), the normal \( n \), and the binormal \( b \), Equation (1) can be written as

\[ \chi_t = cb, \]

with \( c(t, x) \) denoting the curvature. Finally, Hasimoto [10] showed that if the curvature \( c(t, x) \) does not vanish, then the function

\[ \psi(t, x) = c(t, x) e^{i \int_0^x \tau(t,s) \, ds}, \]

that he calls the filament function, solves the focusing cubic non-linear Schrödinger equation (NLS)

\[ i \psi_t + \psi_{xx} + \frac{\psi}{2} (|\psi|^2 - A(t)) = 0 \]

for some real function \( A(t) \) that depends on \( c(0, t) \) and \( \tau(0, t) \). Here \( \tau \) stands for the torsion. The non-vanishing constraint on the curvature has been removed by Koiso [14], by using another frame instead of Frenet’s one.

In view of this link with the nonlinear Schrödinger equation, existence results were given for the initial value problem of the binormal flow with initial data curves with curvature and torsion in high order Sobolev spaces ([10], [14], [8]). The case of less regular closed curves was considered recently by Jerrard and Smets by using a weak version of the binormal flow ([12], [13]). Let us mention also that stability of various types of particular solutions of the binormal flow is a subject of current research (see for instance [6], [15] and the references therein). Also, to emphasize the great complexity of the binormal flow, we recall that in the case of closed curves, various aspects of evolutions of knotted vortices by the binormal flow are studied using geometric and topological methods (as an example, see [18] and the references therein).

We are interested in solutions of (1) that at a given time are regular except at a point where they have a corner. One can use the invariance of the equation under translations in time and in space and assume without loss of generality that the time is \( t = 0 \) and the corner is located at the origin \( (0, 0, 0) \). Let us also note that the equation is reversible in time. This is because if \( \chi(t, x) \) is a solution so is \( \chi(-t, -x) \).
One relevant class of solutions are the self-similar ones, i.e., those that can be written as

$$\chi(t, x) = \sqrt{t} G \left( \frac{x}{\sqrt{t}} \right)$$

for some appropriate $G$. These solutions have been investigated first by physicists in the 80's. In fact it is rather easy to see that, modulo rotations, self-similar solutions are a family of curves $\chi_a$ parametrized by $a \in \mathbb{R}^+\ast$, such that curvature and torsion of $\chi_a(t)$ at $x$ are $\frac{a}{\sqrt{t}}$ and $\frac{a}{t}$ respectively ([16], [17], [5]). From this it is not complicated to conclude that $\chi_a(0)$ has a corner at $(0, 0, 0)$. This fact, together with a characterization and detailed asymptotic of the self-similar solutions was proved in [9]. We reformulate part of Theorem 1 of [9] as follows. Details will be given in the next section.

**Theorem 1.1 (Description of self-similar solutions [9]).** – Let $A^+$ and $A^-$ be any two distinct non-colinear unitary vectors in $\mathbb{R}^3$. Then, there exists a unique self-similar solution $\chi$ for positive times with initial data at time $t = 0$

$$\chi(0, x) = \begin{cases} A^+ x, & x \geq 0, \\ A^- x, & x \leq 0. \end{cases}$$

All self-similar solutions are described in this way. Moreover, if we denote $a \in \mathbb{R}^+\ast$ such that $\sin \left( \frac{A^+ - A^-}{2} \right) = e^{-\pi a^2}, \frac{a}{\sqrt{t}}$, and $\frac{a}{t}$ are respectively the curvature and the torsion of the curve $\chi(t, x)$. Also, there exist two complex vectors $B^\pm$ orthonormal to $A^\pm$ such that

$$B^\pm = \lim_{x \to \pm \infty} (n + ib)(t, x)e^{i \int_0^t \tau(t, s)ds}e^{-ia^2 \log \sqrt{T + ia^2 \log |x|}}.$$ 

Up to a rotation, the coordinates of $A^\pm$ and $B^\pm$ are given explicitly in terms of Gamma functions involving the parameter $a$ (see formulas (55), (57), (47), (48), and (69) in [9]).

Finally, we want to remark that the solution given in the above theorem can be continued as a self-similar solution in a unique way for negative times. This is done as follows. If $\chi$ in the Theorem 1.1 exists for negative times, then $\chi^*(t, x) = \chi(-t, -x)$ with $t > 0$ is a solution for
positive times with initial data $\chi(0, -x)$. In view of Theorem 1.1 it follows that $\chi^*$ is unique, and it is obtained by a rotation of $\chi$ around the axis given by the vector $A^+ - A^-$ and with angle $\pi$. This rotation can be also seen as a composition of a reflection with respect to the plane generated by $A^+$ and $A^-$, and a change of the sense of parametrization -see Figure 1.

Numerical simulations for self-similar solutions have been done by Buttke in [5] and by de la Hoz, García-Cervera and Vega in [11], where a similarity at the qualitative level with the flow across a delta wing is emphasized -see Figure 2.

Last but not least we mention that the binormal flow and its self-similar solution are used to understand the architecture of the myocardium, as shown by Peskin and McQueen in [19].

Next we are going to recall the results we have obtained in our previous papers [2], [3] and [4] about the stability of the self-similar solutions. These results will play a fundamental role in the proofs of the theorems we state in this article.

We start noticing that in the particular case of $\chi_a$ we have that for $t > 0$ its filament function is

$$\psi_a(x, t) = a e^{i \frac{x^2}{4t}}$$

which solves (5) with $A(t) = \frac{|a|^2}{t}$.

$$i \psi_t + \psi_{xx} + \frac{\psi}{2} \left( |\psi|^2 - \frac{a^2}{t} \right) = 0.$$ 

Observe that $|\psi_a|^2 = a^2/t$ and therefore $\psi_a$ does not belong to $L^2(\mathbb{R})$, but is just locally in $L^2$. A simple way of finding a natural function space such that $\psi_a$ belongs to it is to use the so-called pseudo-conformal transformation

$$\psi(t, x) = \mathcal{F} v(t, x) = \frac{e^{i \frac{x^2}{4t}}}{\sqrt{t}} \left( \frac{1}{t}, \frac{x}{t} \right).$$
If $\psi$ is a solution of (5) then $v$ solves
\begin{equation}
iv_t + v_{xx} + \frac{1}{2t} (|v|^2 - a^2) v = 0.
\end{equation}
In particular for $\psi_a$ we obtain the constant solution $v_a = a$. This new equation has the associated energy
\[ E(t) = \int |v_x|^2 - \frac{1}{4t} (|v|^2 - a^2)^2 dx, \]
with $\frac{d}{dt} E(t) = - \frac{1}{4t^2} \int (|v|^2 - a^2)^2 dx$, and $E(t) = 0$ for $v_a$.

We want to consider small perturbations of $v_a$. Then, we write $v = u + a$ so that $u$ must be a solution of the following equation
\begin{equation}
iu_t + u_{xx} + \frac{a + u}{2t} (|a + u|^2 - a^2) = 0.
\end{equation}
As a conclusion, understanding the large time behavior of the solutions of (10) is equivalent to understanding the behavior of the perturbations of $\psi_a$ in (7) at time $t = 0$ which in turn is related to the behavior of small perturbations of the self-similar solution $\chi_a$ at the time that the corner is created.

In [2] we start our study of the scattering properties for Equation (10). In particular we obtain a first result about the existence of the wave operator. For $s \in \mathbb{N}^*$ we denote $H^s$ the usual Sobolev space in $\mathbb{R}$ of $L^2$ functions with $s$-derivatives in $L(2)$, $W^{s,1}$ the space of $L^1$ functions with $s$-derivatives in $L^1$, and $\dot{H}^s$ the corresponding homogeneous space of functions with $s$-derivatives in $L^2$. Finally $\dot{H}^{-2}$ denotes the set of tempered distributions $\phi$ such that
\begin{equation}
\int |\phi(\xi)|^2 \frac{d\xi}{|\xi|^4} < \infty.
\end{equation}
Then, we show in [2] that for any $a$ small and any $f_+$ small in $\dot{H}^{-2} \cap H^s \cap W^{s,1}$, there exists a unique $u \in C([1, \infty), \dot{H}^s(\mathbb{R}))$ solution of (10) having $f_+$ as asymptotic state: for any $1 \leq k \leq s$,
\[ \sup_{1 \leq t} \left\| u(t) - e^{t/2} \log t e^{i(t-1)\phi_+} f_+ \right\|_{L^2} + \sup_{1 \leq t} \left\| u(t) - e^{t/2} \log t e^{i(t-1)\phi_+} f_+ \right\|_{H^s} \leq C(a, f_+). \]
Moreover if $f_+ \in \dot{H}^{-2} \cap H^3 \cap W^{3,1}$ and $x^2 f_+ \in L^2$ then we construct in [2] some perturbations $\chi(t, x)$ of $\chi_0$, that are solutions of the binormal flow on $0 \leq t \leq 1$, and that still have a “corner” at time $0$. So in [2] we proved that the development of a singularity in finite time for the self-similar solutions of (1) is not an isolated phenomena. Although assumption (11) is very strong, we obtain the extra bonus of proving that not just the perturbed solution remains close to the self-similar solution but also that the full Frenet frame is close to the starting one. In particular the binormal vectors also remain close and therefore from (3) we obtain a much more precise information about the velocity of the perturbed filament.

In [3] we are able to avoid the assumption (11) and the smallness hypothesis on $a$. For doing so we introduce some function spaces that give special consideration to the low Fourier ANNALES SCIENTIFIQUES DE L’ÉCOLE NORMALE SUPÉRIEURE
modes. More concretely we consider
\begin{equation}
\|f(x)\|_{X_{t_0}^{\gamma}} = \frac{1}{t_0^\delta} \|f\|_{L^2} + \frac{t_0^\gamma}{\sqrt{t_0}} \|\xi^{2\gamma} \hat{f}(\xi)\|_{L^\infty(\xi^2 \leq 1)} < +\infty
\end{equation}
and \(Y_{t_0}^{\gamma}\) the space of functions
\begin{equation}
\|g(t, x)\|_{Y_{t_0}^{\gamma}} = \sup_{t \geq t_0} \left( \frac{1}{t_0^\delta} \|g(t)\|_{L^2} + \left( \frac{t_0^\gamma}{t} \right) \frac{t_0^\gamma}{\sqrt{t_0}} \|\xi^{2\gamma} \hat{g}(\xi)\|_{L^\infty(\xi^2 \leq 1)} \right) < +\infty;
\end{equation}
for simplicity we shall drop in the notations the subindex \(t_0\) when \(t_0 = 1\). Let us notice that in view of Lemma 6.1 in \([4]\) the following results are valid in spaces \(Y^\gamma\) where the power \(a^2\) is replaced by any \(\delta > 0\). We have proved global existence and asymptotic completeness for initial data in \(X^\gamma\). More precisely, for \(s \in \mathbb{N}\) and for small initial data \(\partial^k u(1, x) \in X^\gamma\), \(0 \leq k \leq s\), with \(0 < \gamma < \frac{1}{4}\), we proved that there exists a unique solution \(u\) of \((10)\), with \(\partial^k u \in Y^\gamma \cap L^4((1, \infty), L^\infty)\), and there exists \(f_+ \in H^s\) for which
\[
\sup_{1 \leq t} t^{\frac{1}{4} - \gamma^+} \left\| u(t) - e^{i\frac{2\gamma}{3} \log t e^{i(t-1)\partial^2} f_+} \right\|_{H^s} \leq C(a, u(1)),
\]
and \(\partial^k f_+\) belongs to \(X^{\gamma^+}\). Moreover, we constructed wave operators in the appendix of \([3]\) without smallness assumption on \(a\): for asymptotic states \(f_+\) with \(\partial^k f_+\) small in \(X^\gamma\), there exists a unique solution \(u\) of \((10)\), with \(\partial^k u \in Y^{\gamma^+} \cap L^4((1, \infty), L^\infty)\) such that
\[
\sup_{1 \leq t} t^{\frac{1}{4} - \gamma^+} \left\| u(t) - e^{i\frac{2\gamma}{3} \log t e^{i(t-1)\partial^2} f_+} \right\|_{H^s} \leq C(a, f_+).
\]
As a consequence of the asymptotic completeness, at the level of the binormal flow \((1)\) we have obtained in \([3]\) that in our functional setting all small perturbations at time \(t = 1\) of \(\chi_\alpha\) will end up generating a singularity in finite time at \(t = 0\). Nevertheless, we do not get too much geometric information about the trace \(\chi(0, x)\) of \(\chi(t, x)\) at \(t = 0\): for instance we do not obtain the behavior of \(\chi(0, x)\) near \(x = 0\).

In \([4]\) we consider the solutions \(u(t)\) constructed in \([3]\) via asymptotic completeness, and look at the corresponding perturbations \(\chi(t)\) of a self-similar solution \(\chi_\alpha\), started at time \(t = 1\). Adding the extra assumption that the initial datum \(u(1)\) belongs to an appropriate weighted space we are able to get a precise asymptotic in space and in time of the tangent and normal vectors of \(\chi(t)\). This allows us to prove the stability of the self-similar structure of \(\chi_\alpha(t)\), as well as a complete description of the trace at time \(t = 0\) of \(\chi(t)\). In particular we prove that the same corner as the one of \(\chi_\alpha(0)\) is created independently of the perturbation.

Two main questions remain open after the paper \([4]\). One is if it is possible to solve the binormal flow forward in time starting with a datum that has a corner at one point. In other words to prove that the initial value problem is well posed for data that are regular except at one point where they have a corner. The second one is whether or not when going backward in time, and once the corner has been created, the solution can be continued for negative times. We answer positively to both questions in this paper. The main obstruction we have to bypass is the use that we make in \([4]\) of weighted spaces because, as we will see in the appendix, they are spaces that the scattering operator of the linearized equation associated to \((10)\) does not leave invariant.
Our main results are the following ones.

**Theorem 1.2** (The initial value problem). – Let \( \chi_0 \) be a smooth curve of class \( C^4 \), except at \( \chi_0(0) = 0 \) where a corner is located, i.e., that there exist \( A^+ \) and \( A^- \) two distinct non-collinear unitary vectors in \( \mathbb{R}^3 \) such that

\[
\chi_0'(0^+) = A^+, \quad \chi_0'(0^-) = A^-.
\]

We set \( a \) to be the parameter of the unique self similar solution of the binormal flow with the same corner as \( \chi_0 \) at time 0.

We suppose \( \chi_0 \) to be such that its curvature \( c(x) \) for \( x \neq 0 \) satisfies \((1 + |x|^4)c(x) \in L^2 \) and \( |x|^{2\gamma}c(x) \in L^\infty_{(|x| \leq 1)} \) small with respect to \( a \) for some \( 0 < \gamma < \frac{1}{4} \).

Then there exists

\[
\chi(t, x) \in C([-1, 1], Lip) \cap C([-1, 1] \setminus \{0\}, C^4),
\]

regular solution of the binormal flow (1) for \( t \in [-1, 1] \setminus \{0\} \), having \( \chi_0 \) as limit at time \( t = 0 \). Above Lip denotes the set of Lipschitz functions.

Moreover, the solution \( \chi \) is unique in the subset of \( C([-1, 1], Lip) \cap C([-1, 1] \setminus \{0\}, C^4) \) such that the associated filament functions at times \( \pm 1 \) can be written as \((a + u(\pm 1, x))e^{\pm \gamma} \) with \( u(\pm 1) \) small in \( X^\gamma \cap H^4 \) with respect to \( a \) for some \( 0 < \gamma < \frac{1}{4} \).

This solution enjoys the following properties:

(i) There exists a constant \( C > 0 \) such that for \( t \in [-1, 1] \) we have the rate of convergence

\[
\sup_x |\chi(t, x) - \chi_0(x)| \leq C \sqrt{|t|}.
\]

(ii) For all fixed \( t_1, t_2 \in [-1, 1] \setminus \{0\} \) the following asymptotic properties hold

\[
\chi(t_1, x) - \chi(t_2, x) = \Theta \left( \frac{\sqrt{t}}{x} \right), \quad T(t_1, x) - T(t_2, x) = \Theta \left( \frac{1}{x^2} \right).
\]

Moreover, there exists \( T^\infty \in \mathbb{S}^2 \) such that uniformly in \( t \in [-1, 1] \), for \( x \) positive,

\[
T(t, x) - T^\infty = \Theta \left( \frac{1}{\sqrt{x^2}} \right).
\]

(iii) \( \chi \) is a solution of the binormal flow for \( t \in [-1, 1] \) in the following weak sense

\[
\int_{-1}^1 \int \chi_t(t, x) \phi(t, x) \, dx \, dt = \int_{-1}^1 \int \chi_x(t, x) + \chi_{xx}(t, x) \phi(t, x) \, dx \, dt < \infty,
\]

for all test functions \( \phi \in C_0^\infty(\mathbb{R}^2) \).

(iv) The tangent vector \( T = \chi_x \) satisfies (2) for \( t \in [-1, 1] \setminus \{0\} \) and tends at \( t = 0 \) to \( T(0) = \chi_0'(0) = T_0 \) for \( x \neq 0 \), with a rate of decay

\[
\sup_{|x| > \epsilon > 0} |T(t, x) - T_0(x)| \leq C_1 |t|^\frac{\gamma}{2}.
\]

(v) The tangent vector \( T \) is a solution of (2) through \( t = 0 \) in the following weak sense

\[
\int_{-1}^1 \int T(t, x) \phi_t(t, x) \, dx \, dt = \int_{-1}^1 \int T(t, x) \wedge T_x(t, x) \phi_x(t, x) \, dx \, dt < \infty,
\]

for all test functions \( \phi \in C_0^\infty(\mathbb{R}^2) \).
THEOREM 1.3 (Continuation of solutions through the singularity time)

Let \( \chi(1) \) be a small perturbation of a self-similar solution \( \chi_0 \) at time \( t = 1 \) in the sense that the filament function (4) of \( \chi(1) \) is \( (a + u(1, x))e^{t \frac{a}{2}} \), with \( u(1) \) small in \( X^\gamma \cap H^4 \) with respect to \( a \) for some \( 0 < \gamma < \frac{1}{4} \). Then, we can construct a regular solution \( \chi \) for the binormal flow (1) on \( t \in [-1, 1] \setminus \{0\} \), having at time \( t = 0 \) a limit \( \chi_0 \) and enjoying the properties i)-v) of Theorem 1.2. Moreover, the corner of the self-similar solution is recovered: \( \partial_a \chi(0, 0^\pm) = \partial_a \chi_0(0, 0^\pm) \).

This solution \( \chi \) is unique in the subset of \( C([-1, 1], \text{Lip}) \cap \mathcal{C}([-1, 1] \setminus \{0\}, \mathcal{C}^4) \) such that the associated filament functions at times \( \pm 1 \) can be written as \( (a + u(\pm 1, x))e^{t \frac{a}{2}} \) with \( u(\pm 1) \) small in \( X^\gamma \cap H^4 \) with respect to \( a \) for some \( 0 < \gamma < \frac{1}{4} \).

Let us briefly explain the proof of Theorem 1.2. We recall the notation \( B^\pm \) for the complex vector appearing in the asymptotics of the normals vectors of the unique self similar solution of the binormal flow with the same corner as \( \chi_0 \) at time 0 (see Theorem 1.1). We denote \( T_0 = \chi_0 \). We define for \( x > 0 \) a complex-valued function \( \bar{g} \) and a \( C^3 \)-valued function \( \bar{N}_0 \) orthonormal to \( T_0 \) by solving the system

\[
\begin{cases}
T_{0x}(x) = \Re(\bar{g}(x)\bar{N}_0(x)), \\
\bar{N}_{0x}(x) = -\bar{g}(x)T_0(x),
\end{cases}
\]

with initial data \( (A^+, B^+) \). We define \( g(x) \) and \( \bar{N}_0 \) similarly for \( x < 0 \) imposing \( (A^-, B^-) \) as initial data in (27). In particular we have the following link with the curvature of \( \chi_0 \): \( |g(x)| = c(x) \). Therefore \( \Re(1 + |x|^4)g(x) \in L^2 \) and \( |x|^2 g(x) \in L^\infty_{(x^2 \leq 1)} \) are small with respect to \( a \). Next we define

\[
f_+ = \mathcal{F}^{-1} \left( g(2 \cdot e^{ia^2 \log |2^i|}) \right).
\]

In particular \( f_+ \) and its first four derivatives are small in \( X_1^\gamma \) with respect to \( a \). This allows us to obtain \( u(t) \) the solution of (10) with asymptotic state \( f_+ \), given by the construction of wave operators in [3]. We set \( \chi \) to be the corresponding binormal flow solution (for the construction see for instance the appendix of [2]). It was also showed in [3] that \( u(1) \in X^\gamma \). We shall prove that we can carry on \( u(t) \) the computations done in [4], so we can define for \( \chi \) a trace at time zero \( T(0, x) \). We recall that in [4] we were working with solutions \( u(t) \) generated by initial data at finite time \( t = 1 \). We used that the weight condition \( x^2 u(t) \in L^2 \) holds, something that is satisfied if we assume it at initial time \( t = 1 \). But now we have to go backwards in time from the asymptotic state \( f_+ \) to the solution \( u(t) \) and as we already said there seems to be a serious obstruction for showing that in this case \( u(t) \) is in weighted spaces; we give the details in the appendix. In §3.1-3.2 we shall perform on \( u(t) \) the computations done in [4], in such a way that we can avoid the assumptions on weights. Finally we shall prove in §3.3 that the trace \( T(0, x) \) coincides with \( T_0(x) \), which will give us the solution of Theorem 1.2 for \( t \geq 0 \). Our uniqueness result relies on the existence and uniqueness of the solution of the associated Frenet system and NLS equations. For negative times we shall do the same, starting from

\[
\mathcal{F}^{-1} \left( \bar{g}(2 \cdot e^{ia^2 \log |2^i|}) \right).
\]
We shall find similarly a solution $\chi^*$ of the binormal flow with initial data $\chi^*(0, x) = \chi(0, -x)$. Then for negative times we shall set $\chi(-t, x) = \chi^*(-t, x)$ to obtain the solution in Theorem 1.2 on $[-1, 1]$.

Concerning Theorem 1.3 we recall that its part concerning positive times $t \geq 0$ was the main result in [4], under the assumption that weighted conditions are satisfied for $u(1)$. As we have said, in §3.1-3.2 we shall remove these conditions. For extending $\chi$ to negative times, we shall proceed as explained above for Theorem 1.2.

The paper is organized as follows. In the following section we shall recall the results in [9] on self-similar solutions of the binormal and describe the continuation through time 0. In Section 3 we shall give the proof of Theorem 1.2 while Theorem 1.3 will be treated in Section 4. The appendix will contain results and remarks on the Equation (10) in weighted spaces, via the so-called $J$-operators, $J(t) = x + it\partial_x$.

2. Self-similar solutions of the binormal flow

In this section we review the known results on self-similar solutions of the binormal flow, i.e.,

$$\chi(t, x) = \sqrt{t} G \left( \frac{x}{\sqrt{t}} \right), \quad t \geq 0,$$

and focus on the issue of their possible extension for negative times. These solutions have been investigated first by physicists in the 80’s ([16], [17], [5]). Using the Frenet equations they observed that, modulo rotations, self-similar solutions form a one parameter family $\chi_a$ of curves with $a \in \mathbb{R}^+$ such that the curvature and the torsion of $\chi_a(t)$ at $x$ are $a\sqrt{t}$ and $x^2 t$ respectively. The mathematical rigorous description was given in [9]. Using the expressions of the derivative in time of the tangent and normal vectors of a solution of the binormal flow, one gets that $(T_a, n_a, b_a)(t, 0)$ is constant in time. Therefore by integrating the binormal flow at $t = 0$ it follows that

$$\chi_a(t, 0) = 2a\sqrt{t} b_a(t, 0).$$

In particular, the curve profile $G_a(x)$ satisfies $G_a(0) = 2a b_a(t, 0)$, so the only degree of freedom in constructing a self-similar solution is in the choice of the Frenet frame at $x = 0$. Theorem 1 of [9] states that given $a \in \mathbb{R}^+$ there exists a unique frame $(T_a, n_a, b_a)(t, x)$ solution of the Frenet system of equations

$$\begin{align*}
T_x &= cn, \\
n_x &= -cT + \tau b \\
b_x &= -\tau b,
\end{align*}$$

with the curvature and the torsion $(c_a, \tau_a)(t, x) = \left( \frac{a}{\sqrt{t}}, \frac{x^2}{2t} \right)$ and taking the canonical basis of $\mathbb{R}^3$ as the initial data at $(t, 0)$. As a consequence there is a unique self-similar solution $\chi_a$.
of the binormal flow such that its Frenet frame at \( x = 0 \) is the canonical basis of \( \mathbb{R}^3 \). This solution is written as

\[
\chi_a(t, x) = \sqrt{t} G_a \left( \frac{x}{\sqrt{t}} \right), \quad t \geq 0,
\]

with the profile \( G_a(\frac{x}{\sqrt{t}}) = 2a b_a(0, 0) + \int_0^{\frac{x}{\sqrt{t}}} T(t, s) \, ds \). Then (21) becomes

\[
\chi_a(t, 0) = 2a \sqrt{t} (0, 0, 1), \quad t \geq 0.
\]

Moreover, in [9] a precise description of the profile \( G_a(s) \) is given for large \( |s| \) (here \( s \) stands for the self-similar variable: \( s = \frac{x}{\sqrt{t}} \)). This asymptotic plays a crucial role in the proof of Theorem 1.1 in [4] as well as in the proofs of Theorem 1.2 and Theorem 1.3 of this paper.

More concretely in [9] the following result is proved.

**Theorem 2.1** ([9]). – *Given \( a > 0 \) then the family of curves*

\[
\chi_a(t, x) = \sqrt{t} G_a \left( \frac{x}{\sqrt{t}} \right),
\]

*with \( G_a \) given in (23) (i.e., the Frenet frame \((T_a, n_a, b_a)\) at \( x = 0 \) is the canonical orthonormal basis of \( \mathbb{R}^3 \)) is a solution of the binormal flow which is real analytic for \( t > 0 \). Moreover, there exist \( A^\pm_a \) and \( B^\pm_a \) such that*

(i) \[
|\chi_a(t, x) - A^+ x 1_{[0, \infty]}(x) - A^- x 1_{-\infty, 0}(x)| \leq a \sqrt{t},
\]

(ii) *The following asymptotics hold, for \( s \to \pm \infty \):

\[
G_a(s) = A^\pm_a \left( s + \frac{2a^2}{s} \right) - 4a \frac{s}{s^2} n_a + O \left( \frac{1}{s^2} \right),
\]

\[
T_a(s) = A^\pm_a - \frac{2a}{s} b_a + O \left( \frac{1}{s^2} \right),
\]

\[
(n_a - ib_a)(s) = B^\pm_a e^{i \frac{a^2}{4s}} e^{i a^2 \log |s|} + O \left( \frac{1}{s} \right),
\]

(iii) *The real vectors \( A^\pm_a = (A^\pm_{a,1}, A^\pm_{a,2}, A^\pm_{a,3}) \) are unitary and*

\[
A^+_{a,1} = A^-_{a,1} = e^{-i \frac{a^2}{2}}, \quad A^+_{a,2} = -A^-_{a,2}, \quad A^+_{a,3} = -A^-_{a,3}, \quad A^+_a \perp B^+_a,
\]

(iv) *The complex vectors \( B^\pm_a = (B^\pm_{a,1}, B^\pm_{a,2}, B^\pm_{a,3}) \) verify \( |\Re B^\pm_a| = |\Im B^\pm_a| = 1 \) and*

\[
B^+_{a,1} = -B^-_{a,1}, \quad B^+_{a,2} = B^-_{a,2}, \quad B^+_{a,3} = B^-_{a,3},
\]

(v) *The angle of the corner of \( \chi_a(0) \) is determined by*

\[
\sin \left( \frac{A^+ - A^-}{2} \right) = A^\pm_{a,1} = e^{-i \frac{a^2}{2}}.
\]
Keeping in mind that the binormal flow is invariant under rotations, Theorem 1.1 is a reformulation of part of this theorem.

As mentioned in the introduction, there is a unique form to continue the solution \( \chi \) in Theorem 1.1 for negative times \( t < 0 \) in a self-similar way. This is done taking \( \chi_a(t,x) = \chi_a^*(-t,-x) \), where \( \chi_a^* \) is a solution of the binormal flow for positive times with initial data \( \chi_a(0,-x) \). Theorem 1.1 ensures us that \( \chi_a^* \) is unique. As a consequence, the unique way to extend \( \chi_a \) for negative times is to perform a rotation of \( \chi_a \) around the axis given by \( A^+_a - A^-_a \) and with angle \( \pi \). This rotation, that we shall call \( \rho_a \), can also be seen as a composition of a reflection with respect to the plane generated by \( A^+_a \) and \( A^-_a \), and a change of the sense of parametrization. Moreover, the trajectory of the origin for negative times is given by

\[
\chi_a(t,0) = 2a\sqrt{|t|} \rho_a(0,0,1) \quad t < 0.
\]

That is to say, the trajectory \( \chi_a(t,0) \) is given by two lines that join together at \( t = 0 \) with an angle that is determined by \( A^+_a \). See Theorem 1 in [9].

Hereafter and for simplicity we shall drop the subindex \( a \) that we have used so far to parametrize the family of self-similar solutions.

We denote by \( \Pi \) the plane generated by \( A^+ \) and \( A^- \) and by \( \Pi^\circ \) the orthogonal plane generated by \( A^+ - A^- \) and \( A^+ \wedge A^- \). We also introduce \( \Pi^\pm \) the plane generated by \( \Re B^\pm \) and \( \Im B \). Since \( B^\pm \perp A^\pm \) we have that \( \Pi^\pm \) is the orthogonal plane to \( A^\pm \). We shall need the following proposition in the proof of Theorem 1.2 and Theorem 1.3.

**Proposition 2.2.** – The self similar solution \( \chi^* \) of the binormal flow with initial data

\[
\chi^*(0,x) = \chi(0,-x) = \begin{cases} 
-A^-x, & x \geq 0, \\
-A^+x, & x \leq 0 
\end{cases}
\]

has the following properties

\[
A^{\pm*} = \rho(A^\pm) = -A^\mp = R^\mp(-A^\mp), \quad B^{\pm*} = \rho(B^\pm) = R^\mp B^\mp,
\]

where \( R^\mp \) is a rotation of angle \( 2\theta \) in the plane \( \Pi^\mp \) and \( \theta \) is the angle between \( \Re B^\mp \) and the plane \( \Pi \).

**Proof.** – We have already seen that \( \chi^*(t,x) = \rho(\chi(t,x)) \) so that \((T^*, n^*, b^*)(t,x) = \rho(T,n,b)(t,x) \) and \((c^*, \tau^*)(t,x) = (c, \tau)(t,x) \). Then, it is easy to see that \( T^*(t,x) \) goes to \(-A^- \) as \( x \) goes to \(+\infty \), and to \(-A^+ \) as \( x \) goes to \(-\infty \). Since \( \rho(A^\pm) = -A^\mp \), we obtain that \( A^{\pm*} = -A^\mp \). We are left with seeing what is \( B^{\pm*} \) in terms of \( B^\pm \).

By definition, since the torsion of \( \chi(t,s) \) is \( \frac{2}{\rho} \),

\[
B^\pm = \lim_{s \to \pm \infty} (n^*+ib^*)(t,x)e^{i\frac{2}{\rho} \sqrt{|s|} + i \rho t \log |x|} = \lim_{s \to \pm \infty} N(t,x) e^{-i \rho^2 \log \sqrt{|s|} + i \rho t \log |x|}.
\]

Since \( (n^*, b^*)(t,x) = \rho(n,b)(t,x) \) and \( \tau^*(t,x) = \tau(t,x) \),

\[
N^*(t,x) = (n^*+ib^*)(t,x)e^{i\int_{-\infty}^{t} \tau^*(t,s)ds} = (\rho n + i \rho b)(t,x)e^{i\frac{2}{\rho} \sqrt{|s|} + i \rho t \log |x|} = \rho N(t,x).
\]

In particular

\[
B^{\pm*} = \rho B^\pm.
\]
From (25) we conclude that $B^+$ is a reflection of $B^-$ with respect to the plane $x_1 = 0$, which is precisely the plane $\Pi^o$. The rotation $\rho$ can also be seen as a composition of a reflection with respect to the plane $\Pi$ with a reflection with respect to the plane $\Pi^o$. Therefore $\rho B^-$ is a reflection of $B^+$ with respect to the plane $\Pi$. In view of the definition of $B^+$ we obtain $\Re B^+ \perp \Im B^+$. It follows then that the reflection of $\Re B^+$ with respect to the plane $\Pi$ is $\Re B^+ \perp \Re B^+$, and the one of $\Im B^+$ is $\Re B^+ \perp \Im B^+$. As a conclusion $B^{+\ast} = \Re B^+ \perp \Im B^+$ (see Figure 3). Moreover, since $A^+$ is orthogonal to $\Pi^+$, it follows that $A^{+\ast} = -A^+ = \Re B^+ \perp \Im B^+$. Again, since $B^+$ is a reflection of $B^-$ with respect to $\Pi_0$, the angle between $B^-$ and the plane generated by $A^+$ and $A^-$ is also $\theta$ and similarly we get $B^{-\ast} = \Re B^+ \perp \Im B^+$.  

3. Proof of Theorem 1.2

As announced in the introduction, we construct a function $f_+$ from the curve $\chi_0$ in Theorem 1.2 as follows. We recall the notation $B^\pm$ for the complex vector appearing in the asymptotics of the normals vectors of the unique self similar solution of the binormal flow with the same corner as $\chi_0$ at time 0 (see Theorem 1.1). We denote $T_0 = \chi_0$. We define for $x > 0$ a complex-valued function $g$ and a $C^3$-valued function $\tilde{N}_0$ orthonormal to $T_0$ by solving the system

$$
\begin{cases}
T_{0x}(x) = \Re(g(x)\tilde{N}_0(x)), \\
\tilde{N}_{0x}(x) = -\overline{g}(x)T_0(x),
\end{cases}
$$

(27)
with initial data \((A^+, B^+)\). We define \(g(x)\) and \(\tilde{N}_0\) similarly for \(x < 0\) imposing \((A^-, B^-)\) as initial data in (27). In particular we have the following link with the curvature of \(\chi_0\): \([g(x)] = c(x)\). Therefore \((1 + |x|^2)g \in L^2\) and \(|x|^2g(x) \in L^6_{(x^2 \leq 1)}\) are small with respect to \(a\). Next we define

\[
f_+ = \mathcal{F}^{-1} \left( g(2^e) e^{a^2 \log |x|} \right).
\]

In particular \(f_+\) and its first 4 derivatives are small in \(X^\gamma\) with respect to \(a\). We let \(u(t, x)\) be the solution of (10) with asymptotic state \(f_+\), given by the construction of wave operators in [3]. It was also shown in [3] that \(u(1, x)\) and its first 4 derivatives belong to \(X^\gamma\). The following bounds hold for all \(0 \leq k \leq 4\) and \(t_1 \leq t_2 < \infty\)

\[
\exists C(a), \tilde{C}(a), \|\partial_x^k u(1/t)\|_{L^\infty[t_1, t_2], H^2} \leq C(a) \sum_{j=0}^4 \|\partial_x^j u(1)\|_{X^{\gamma+}} \leq \tilde{C}(a) \sum_{j=0}^4 \|\partial_x^j f_+\|_{X^\gamma}.
\]

Next we define \(\psi\) by the pseudo-conformal transformation (8),

\[
\psi(t, x) = \mathcal{F}(a + u)(t, x) = e^{i \frac{t^x}{\sqrt{t}} a} + a \left( \frac{1}{t} , \frac{x}{t} \right).
\]

Finally we construct \(\chi(t, x)\) to be the corresponding solution of the binormal flow for \(t \geq 0\), i.e., with curvature \(c(t, x) = |\psi(t, x)|\) and torsion \(\tau(t, x) = \partial_x \arg \psi(t, x)\), having as initial data at time \(t_0 > 0\) the location \(\chi(t_0, 0) = (0, 0, 0)\) and as Frenet frame \((T, n, b)(t_0, 0)\) the canonical orthonormal basis of \(\mathbb{R}^3\). The curve \(\chi(t)\) has curvature close to \(\frac{\psi}{t}\), and since it satisfies the binormal flow it follows that it has a trace at time \(t = 0\). In particular \(\chi(0, 0)\) is a point in \(\mathbb{R}^3\). We translate \(\chi\) in space such that \(\chi(0, 0) = \chi_0(0)\). Let \((T, n, b)(t, x)\) be its (very oscillating) Frenet frame for \(t > 0\) and consider the following complex normal vectors

\[
N(t, x) = (n + ib)(t, x)e^{i \int_0^t \tau(t, s)ds}, \quad \tilde{N} = Ne^{i\Phi} \text{ with } \Phi(t, x) = -a^2 \log \sqrt{t} + a^2 \log |x|.
\]

We shall prove in the next two subsections that for \(x \neq 0\) the tangent vector \(T(t, x)\) has a limit as \(t\) goes to 0, and eventually in §3.3 that modulo a rotation this limit is precisely \(T_0(x)\), so modulo a rotation \(\chi(0, x) = \chi_0(x)\). Then we shall show the uniqueness of \(\chi\). Finally, in §3.4 we shall extend \(\chi(t, x)\) for negative times and end the proof of Theorem 1.2.

### 3.1. Asymptotic behaviour in time and space for the tangent vector

We start first with an asymptotic analysis of tangent and normal vectors, keeping track of both time and space variables.

---

\(\chi(t, x)\) is defined as \(\chi(t_0, 0) = (0, 0, 0) + \int_0^t (T \wedge T_{xx})(\tau, 0) d\tau + \int_0^t T(t, s) ds\), is a solution of the binormal flow. For details one can see for instance the appendix of [2] where the same type of construction is done using the Frenet frame instead of the \((T, N)\) frame, the link between the two constructions being that the two frames are related by the normal rotation \(N(t, x) = (n + ib)(t, x)e^{i \int_0^t \tau(t, s)ds}\).
Then use the approximation of \( t \), tends to zero as
\[
T(t,x) - T^\pm \leq C\|\partial_x u(1)\|_{X^+} \frac{1}{|x|} + C_1 \sqrt{t},
\]
and the notations
\[
N(t,x) - N^\pm \leq C\|\partial_x u(1)\|_{X^+} \frac{1}{|x|} + C_2 \left( \sqrt{t} + \frac{t}{x^2} + \sqrt{t} \right).
\]
Moreover,
\[
(29) \quad T(t,x) - T^\pm + \Im \int_x^{\pm \infty} h(t,s) \tilde{N}(t,s) ds = c_0(t,x),
\]
\[
(30) \quad \tilde{N}(t,x) - N^\pm - i \int_x^{\pm \infty} h(t,s) T(t,s) ds = d_0(t,x),
\]
with
\[
(31) \quad |c_0(t,x)| \leq C_1 \frac{\sqrt{t}}{|x|}, \quad |d_0(t,x)| \leq C_2 \left( \frac{\sqrt{t}}{|x|} + \frac{t}{x^2} + \sqrt{t} \right),
\]
and the notations
\[
h(t,s) = e^{-i\frac{t^2}{2s^2}} \frac{2}{s\sqrt{t}} (u_\pm \left( \frac{1}{s} \right) \left( \frac{t}{s} \right) e^{-is\phi(t,s)},
\]
\[
C_0 = \|u(1)\|_{X,v} + \|\partial_x u(1)\|_{X,v}, \quad C_1 = C(a + C_0), \quad C_2 = C(a + a^2 + (1 + a^2)C_0 + C^2_0).
\]

Proof. – This result was proved in [4] (see formulas (31) and (32)), provided that \( u(1) \) belongs to some weighted space, which is not the case in the present paper. These weighted spaces were used in the proofs formulas (31) and (32) in [4] only for showing that the limit at infinity of the normal vector \( N(t,x) \) is independent of time (Lemma 3.4 in [4]), and more precisely in showing that
\[
(32) \quad \int_1^\infty u \left( \frac{1}{v}, \frac{x}{v} \right) \frac{dt}{v} \xrightarrow{x \to +\infty} 0.
\]

For getting (32) without using weights conditions, and hence obtaining the Proposition, we proceed in here as follows. We have
\[
\int_t^1 u \left( \frac{1}{v}, \frac{x}{v} \right) \frac{dt}{v} \leq \log t \sup_{t' \in [t,1]} u \left( \frac{1}{v}, \frac{x}{v} \right),
\]
so it is enough to prove that
\[
(2) \quad \sup_{t' \in [t,1]} u \left( \frac{1}{v}, \frac{x}{v} \right) \xrightarrow{x \to +\infty} 0.
\]

It is easy to show that
\[
\sup_{t' \in [t,1]} u \left( \frac{1}{v}, x \right)
\]
tends to zero as \( x \) goes to infinity by using the fact that \( u \left( \frac{1}{v}, x \right) \in W^{1,p}([t,1] \times [0,\infty)) \subset L^\infty(\mathbb{R}^2) \) for \( p > 2 \), then use the approximation of \( W^{1,p} \) by \( C^\infty(\mathbb{R}^2) \) functions. The issue is that \( u \left( \frac{1}{v}, x \right) \) is not in \( W^{1,p}([t,1] \times [0,\infty)) \) because when we compute its \( \partial_x \) partial derivative we get a factor \( x \) and therefore weighted spaces are needed this way.
Suppose it does not. Then
\[ \exists \epsilon > 0, \exists x_n \to +\infty, \sup_{t \in [t,1]} \left| u \left( \frac{1}{f}, \frac{x_n}{t} \right) \right| > \epsilon. \]
In particular
\[ \exists t_n \in [t,1], \quad \left| u \left( \frac{1}{f}, \frac{x_n}{t_n} \right) \right| > \frac{99}{100} \epsilon. \]
Since \( u \left( \frac{1}{f} \right) \) is continuous, we obtain
\[ \left\| u \left( \frac{1}{f_n} \right) \right\|_{L^\infty(\mathbb{R}^n, \infty)} > \frac{\epsilon}{2}. \]
Moreover, \( t_n < 1 \) so
\[ \left\| u \left( \frac{1}{f_n} \right) \right\|_{L^\infty(\mathbb{R}^n, \infty)} > \frac{\epsilon}{2}. \]
Now \( t_n \in [t,1] \) so there is a subsequence (that we recall \( t_n \)) and a number \( t_0 \in [t,1] \) such that \( t_n \to t_0 \). We use \( u \in \mathcal{C} \left( \left[ \frac{1}{2}, 1 \right], H^1 \right) \) to get
\[ \left\| u \left( \frac{1}{f_n} \right) - u \left( \frac{1}{f_0} \right) \right\|_{H^1} \to 0, \]
so
\[ \left\| u \left( \frac{1}{f_n} \right) - u \left( \frac{1}{f_0} \right) \right\|_{L^\infty(\mathbb{R}^n, \infty)} \to 0. \]
There exists \( N_\epsilon \) such that for all \( n \geq N_\epsilon \)
\[ \left\| u \left( \frac{1}{f_n} \right) - u \left( \frac{1}{f_0} \right) \right\|_{L^\infty(\mathbb{R}^n, \infty)} \leq \frac{\epsilon}{4}. \]
Since
\[ \left\| u \left( \frac{1}{f_n} \right) \right\|_{L^\infty(\mathbb{R}^n, \infty)} > \frac{\epsilon}{2}, \]
we obtain for all \( n \geq N_\epsilon \)
\[ \left\| u \left( \frac{1}{f_n} \right) \right\|_{L^\infty(\mathbb{R}^n, \infty)} > \frac{\epsilon}{4}. \]
Since \( x_n \) tends to infinity, this is in contradiction with the fact that \( u \left( \frac{1}{f_0} \right) \) belongs to \( H^1 \).

In conclusion, (32) can be proved without weight conditions and the Proposition follows.

\[ \square \]

3.2. The existence of the tangent vector at \( t = 0 \)

In order to obtain the existence of a trace for the tangent vector at \( t = 0 \) we would like to proceed in a way similar to the one in [4] but avoiding the assumption that \( u(t) \) is in weighted spaces. Hence we will re-express in formula (29) the vector \( \tilde{N} \) appearing in the integral by using (30) to obtain an integral equation on \( T \). Our plan is then to solve this equation by iteration as done in [4].

We shall perform the analysis for \( x > 0 \); the case \( x < 0 \) goes the same.
Note that in [4] we were able to iterate this process that generates multiple integrals because we proved (Lemma 4.1 in [4]) that for $t$ small with respect to $x$

$$\int_x^\infty |h(t, s)| ds \leq C_3 + C_4 \frac{t^2}{x},$$

with

$$C_3 = CC_0, \quad C_4 = C(a)(C_0 + \|xu(1)\|_{L^2}),$$

so $C_3$ and $C_4$ are small if $u(1)$ and its derivative are small enough in $X^{\gamma^+}$. However, the proof of this key estimate relied on the fact that $u(t)$ belongs to weighted spaces. In order to avoid the use of weighted space we shall take advantage of the particular form of $h(t, s)$ that involves a derivative in space of $u$. We start by proving a lemma which will be frequently used in this subsection.

We recall that

$$h(t, s) = e^{-\frac{t^2}{2s}} \frac{2}{s^{\frac{1}{2}}} (u_x) \left( \frac{1}{t}, \frac{s}{t} \right) e^{-i\Phi(t, s)} \text{ with } \Phi(t, s) = -a^2 \log \sqrt{t} + a^2 \log |s|.$$

**Lemma 3.2.** There exists a constant $C > 0$ such that for all $n \in \mathbb{N}^*$, $0 < t \leq 1$ and $0 < x$ the following estimate holds

$$\left| \int_x^\infty h_{i_1}(t, s_1) \int_{s_1}^\infty h_{i_2}(t, s_2) \cdots \int_{s_{n-1}}^\infty h_{i_n}(t, s_n) f(t, s_n) ds_n \cdots ds_1 \right| \leq C^n \|u(1/t)\|_{H^n} \left( 1 + \frac{t}{x^2} \right)^{n-1} \left( \left( 1 + \frac{t}{x^2} \right) \|f(t)\|_{L^\infty(x, \infty)} + \frac{t}{x} \|\partial_s f(t)\|_{L^2(\min(x, 1), 1)} \right),$$

where $h_{i_j} \in \{h, \bar{h}\}$ for $1 \leq j \leq n$.

**Proof.** It will follow from the proof below that we can suppose without loss of generality that $h_{i_1} = \cdots = h_{i_n} = h$.

We shall prove the lemma by recursion on $n$. A trivial estimate can be obtained using Cauchy-Schwarz inequality

$$\left| \int_x^\infty h(t, s_1) \int_{s_1}^\infty h(t, s_2) \cdots \int_{s_{n-1}}^\infty h(t, s_n) f(t, s_n) ds_n \cdots ds_1 \right| \leq \frac{\|u_x(1/t)\|_{L^2}}{\sqrt{x}} \|f(t)\|_{L^\infty(x, \infty)}.$$
We use Cauchy-Schwarz and the fact that \( u \) belongs to \( H^1 \) to get
\[
\left| \int_x^\infty h(t, s) f(t, s) \, ds \right| \leq C \| u(1/t) \|_{H^1} \left( \left( 1 + \frac{t}{x^2} \right) \| f(t) \|_{L^\infty(x, \infty)} + \frac{t}{x} \| \partial_x f(t) \|_{L^2(x, 1)} \right),
\]
which proves the bound in (33).

Now we suppose that the lemma holds for all \( 1 \leq k \leq n - 1 \) and we shall prove it for \( n \).

We denote
\[
f_n(t, x) = \int_x^\infty h(t, s_1) \int_s^\infty h(t, s_2) \cdots \int_{s_{n-1}}^\infty h(t, s_n) \, ds_n \cdots ds_1, \quad f_0(t, x) = f(t, x).
\]

In particular
\[
f_n(t, x) = \int_x^\infty h(t, s_1) f_{n-1}(t, s_1) \, ds_1.
\]

We perform now an integration by parts in the variable \( s_1 \) on \([x, 1]\),
\[
f_n(t, x) = \int_1^\infty h(t, s) f_{n-1}(t, s_1) \, ds_1 + 2\sqrt{\pi} e^{-t} \Phi(t, 1) u \left( \frac{1}{t}, \frac{1}{t} \right) f_{n-1}(t, 1)
\]
\[- \frac{2\sqrt{\pi}}{x} e^{-t} \Phi(t, x) u \left( \frac{1}{t}, \frac{x}{t} \right) f_{n-1}(t, x) - \int_x^1 u \left( \frac{1}{t}, \frac{s}{t} \right) \left( \frac{2\sqrt{\pi}}{t} e^{-t} \Phi(t, s) f_{n-1}(t, s) \right) ds.
\]

It follows by Cauchy-Schwarz that
\[
|f_n(t, x)| \leq C \| u(1/t) \|_{H^1} \left( \left( 1 + \frac{t}{x^2} \right) \| f_{n-1}(t) \|_{L^\infty(x, \infty)} + \frac{t}{x} \| \partial_x f_{n-1}(t) \|_{L^2(x, 1)} \right).
\]

Since again by Cauchy-Schwarz
\[
\| \partial_x f_{n-1}(t, s) \|_{L^2(x, 1)} = \| h(t, s) f_{n-2}(t, s) \|_{L^2(x, 1)} \leq C \| u(1/t) \|_{H^1} \frac{1}{x} \| f_{n-2}(t) \|_{L^\infty(x, \infty)},
\]
we get
\[
|f_n(t, x)| \leq C \| u(1/t) \|_{H^1} \left( 1 + \frac{t}{x^2} \right) \| f_{n-1}(t) \|_{L^\infty(x, \infty)} + C \| u(1/t) \|_{H^1}^2 \frac{t}{x^2} \| f_{n-2}(t) \|_{L^\infty(x, \infty)}.
\]

From the recursion hypothesis we have for all \( s \geq x \) and \( 1 \leq k \leq n - 1 \)
\[
|f_k(t, s)| \leq C^k \| u(1/t) \|_{H^1}^k \left( 1 + \frac{t}{x^2} \right)^{k-1} \left( \left( 1 + \frac{t}{x^2} \right) \| f(t) \|_{L^\infty(x, \infty)} + \frac{t}{x} \| \partial_x f(t) \|_{L^2(\min(x, 1), 1)} \right)
\]
and the lemma follows. \( \square \)

We are now able to iterate formulas (29) and (30) as follows.

**Lemma 3.3.** We set \( a_1(t, x) = T^\infty, a_2(t, x) = -\nabla N^{\infty} \int_x^\infty h(t, s) \, ds \) and for \( k \geq 1 \) we define \( a_{2k+1}(t, x) \) by
\[
(-1)^k \int_x^\infty h(t, s_1) \int_s^\infty h(t, s_2) \cdots \int_{s_{2k-1}}^\infty h(t, s_{2k}) T^\infty \, ds_{2k} \cdots ds_1,
\]

**ANNALES SCIENTIFIQUES DE L’ÉCOLE NORMALE SUPÉRIEURE**
and \( a_{2k+2}(t,x) \) by

\[
(-1)^{k+1} \Re \int_x^\infty h(t, s_1) \int_{s_1}^\infty \overline{h(t, s_2)} \cdots \overline{h(t, s_{2k-1})} \int_{s_{2k-1}}^\infty h(t, s_{2k}) \Im \int_x^{s_{2k+1}} h(t, s_{2k+1}) ds_{2k+1} \cdots ds_1.
\]

Then, there exists a constant \( C > 0 \) such that for all \( n \in \mathbb{N}^* \), \( 0 < t \leq 1 \) and \( 0 < x \) the following decomposition holds

\[
T(t, x) = \sum_{j=1}^{2n} a_j(t, x) + b_n(t, x)
\]

with

\[
|b_n(t, x)| \leq C^{2n} \| u(1/t) \|^2_{H^1} (1 + a + \| u(1/t) \|_{L^2}) \left( 1 + \frac{t}{x^2} \right)^{2n} + C_5 \sum_{k=0}^{n-1} C^{2k} \| u(1/t) \|^2_{H^1} \left( 1 + \frac{t}{x^2} \right)^{2k} \left( \sqrt{1 + \frac{\sqrt{t}}{x} + \frac{t^2}{x^4}} \right),
\]

and

\[
C_5 = C(a + a^2 + (1 + a^2)C_0 + (1 + a^2)C_0^2 + C_0^3), \quad C_0 = \| u(1) \|_{X^\gamma} + \| \partial_x u(1) \|_{X^\gamma}.
\]

**Proof.** We start by proving the lemma for \( n = 1 \). Formulas (29) and (30) obtained in Proposition 3.1 give

\[
T(t, x) = T^{+\infty} - \Im N^{+\infty} \int_x^\infty h(t, s) ds - \Re \int_x^\infty h(t, s) \int_s^\infty \overline{h(t, s')} T(t, s') ds' ds + b_0(t, x),
\]

with

\[
b_0(t, x) = c_0(t, x) + \Im \int_x^{\pm\infty} h(t, s) d_0(t, s) ds.
\]

Therefore

\[
b_1(t, x) = -\Re \int_x^\infty h(t, s_1) \int_{s_1}^\infty \overline{h(t, s_2)} T(t, s_2) ds_2 + b_0(t, x).
\]

We use Lemma 3.2 for \( f = T \) and the fact that \( T_s = \Re N \) to get

\[
\left| \Re \int_x^\infty h(t, s_1) \int_{s_1}^\infty \overline{h(t, s_2)} T(t, s_2) ds_2 \right|
\leq C^2 \| u(1/t) \|^2_{H^1} \left( 1 + \frac{t}{x^2} \right) \left( 1 + \| a + u \left( \frac{1}{t}, \frac{x}{t} \right) \|_{L^2(\min(x,1), 1)} \right)
\leq C^2 \| u(1/t) \|^2_{H^1} \left( 1 + a + \| u(1/t) \|_{L^2} \right) \left( 1 + \frac{t}{x^2} \right)^2.
\]

We are left with estimating \( b_0(t, x) \). We deduce from Lemma 4.4 in [4] that for some positive constant \( \tilde{C} \),

\[
|b_0(t, x)| \leq (C_1 + \tilde{C} C_0 (C_2 + a + a^2 + C_0 + C_0^2)) \left( \sqrt{t} + \sqrt{\frac{\sqrt{t}}{x} + \frac{t^2}{x^4}} \right),
\]

therefore we obtain the lemma for \( n = 1 \).
For $n \geq 2$ we note that $b_n$ can be expressed as
\begin{equation}
    b_n(t, x) = \sum_{k=1}^{n-1} (-1)^{k+1} \mathcal{R} \int_{x}^{\infty} h(t, s_1) \int_{s_1}^{\infty} h(t, s_2) \cdots \int_{s_{2k-1}}^{\infty} h(t, s_{2k}) b_0(t, s_{2k}) ds_{2k} \cdots ds_1
\end{equation}
\begin{equation}
+ (-1)^n \mathcal{R} \int_{x}^{\infty} h(t, s_1) \int_{s_1}^{\infty} h(t, s_2) \cdots \int_{s_{2n-1}}^{\infty} h(t, s_{2n-1}) \int_{s_{2n-1}}^{\infty} h(t, s_{2n}) T(t, s_{2n}) ds_{2n} \cdots ds_1.
\end{equation}

For the second multiple integral we use again Lemma 3.2 for $f = T$ and the fact that $T_{s} = \mathcal{R}_{\infty} / N$ to get the upper bound
\[ C^{2n} \| u(1/t) \|_{L^2}^2 \left( 1 + a + \| u(1/t) \|_{L^2} \right) \left( 1 + \frac{t}{x^2} \right)^{2n}. \]

For the first integral we shall use Lemma 3.2 with $f = b_0$:
\begin{equation}
    \left| (-1)^{k+1} \mathcal{R} \int_{x}^{\infty} h(t, s_1) \int_{s_1}^{\infty} h(t, s_2) \cdots \int_{s_{2k-1}}^{\infty} h(t, s_{2k}) b_0(t, s_{2k}) ds_{2k} \cdots ds_1 \right|
\end{equation}
\[ \leq C^{2k} \| u(1/t) \|_{L^2}^2 \left( 1 + \frac{t}{x^2} \right)^{2k-1} \left( 1 + \frac{t}{x^2} \right) \| b_0(t) \|_{L^\infty(x, \infty)} + \frac{t}{x} \| \partial_x b_0(t) \|_{L^2(x, \infty)}. \]

We have already the $L^\infty$ bound (37) on $b_0$. Since integrating by parts in the space variable from the quadratic phase of $h$ the integral in (29), one gets (see for instance [4], page 10)
\[ c_0(t, x) = -\mathcal{R} \frac{2t}{ix} \psi(t, x) N(t, x) - \mathcal{R} \int_{x}^{\infty} \frac{2t}{is^2} \psi(t, s) N(t, s) ds - \mathcal{R} \int_{x}^{\infty} \frac{2t}{is} \overline{\psi(t, s)} N_s(t, s) ds, \]

it is easy to see that
\[ \frac{t}{x} \| \partial_x c_0(t) \|_{L^2(x, \infty, 1)} \leq (a + a^2 + \| u(1/t) \|_{H^1} + \| u(1/t) \|_{H^1}^2) \left( \frac{\sqrt{t}}{x} + \frac{t}{x^2} + \frac{\sqrt{t}}{x^3} \right). \]

So we get by Cauchy-Schwarz and (31)
\begin{equation}
    \frac{t}{x} \| \partial_x b_0(t) \|_{L^2(x, \infty, 1)} \leq \frac{t}{x} \| \partial_x c_0(t) \|_{L^2(x, \infty, 1)} + \frac{t}{x} \| u(1/t) \|_{H^1} \| d_0(t) \|_{L^\infty(x, \infty)}
\end{equation}
\[ \leq C (a + a^2 + \| u(1/t) \|_{H^1} + \| u(1/t) \|_{H^1}^2 + \| u(1/t) \|_{H^1} C_2) \left( \frac{\sqrt{t}}{x} + \frac{\sqrt{t}}{x^2} + \frac{\sqrt{t}}{x^3} \right). \]

Therefore estimates (39), (37) and (40) and
\[ \| u(1/t) \|_{H^1} \leq C (\| u(1) \|_{X^{-}^{1/2}} + \| \partial_x u(1) \|_{X^{-}^{1/2}}) = C_0, \]
yield
\[ \left| (-1)^{k+1} \mathcal{R} \int_{x}^{\infty} h(t, s_1) \int_{s_1}^{\infty} h(t, s_2) \cdots \int_{s_{2k-1}}^{\infty} h(t, s_{2k}) b_0(t, s_{2k}) ds_{2k} \cdots ds_1 \right|
\end{equation}
\[ \leq C^{2k} \| u(1/t) \|_{H^1}^2 \left( 1 + \frac{t}{x^2} \right)^{2k} C_5 \left( \frac{\sqrt{t}}{x} + \frac{\sqrt{t}}{x^2} + \frac{\sqrt{t}}{x^3} \right), \]

so the lemma follows.
Our next aim is to replace each occurrence of \( h(t, s) \) in \( a_j(t, x) \) by a function independent of time \( \tilde{h}(s) \),

\[
\tilde{h}(x) = i \int_{\mathbb{R}} \left( \frac{x}{2} \right) e^{-ia^2 \log |x|} ds,
\]

up to getting a small error term. This will lead us to eventually identify the limit of \( T(t, x) \) when \( t \) goes to 0.

**Lemma 3.4.** There exists a constant \( \tilde{C} > 0 \) such that for all \( g \in L^\infty \) with \( g_s \in L^1 \cap L^2 \), \( 0 < \gamma \leq \tilde{x} \),

\[
\left| \int^\gamma_x (h(t, s) - \tilde{h}(s))g(s) \, ds \right| \leq \tilde{C} \left( \|g\|_{L^\infty(x, \gamma)} + \|g_s\|_{L^1(x, \gamma)} \right) \left( \frac{\sqrt{t}}{x} + t \right),
\]

with

\[
\tilde{C} = \tilde{C}(\|u_1\|_{X^{\gamma, +}} + \|\partial_x u_1\|_{X^{\gamma, +}} + \|\partial_x^2 u_1\|_{X^{\gamma, +}}).
\]

The proof of this result goes exactly like the one of Lemma 4.3 in [4] because in that one we did not use the weight condition. In fact, note that the asymptotic state \( f_+ \) does not belong in general to weighted spaces.

**Lemma 3.5.** There exists a constant \( C > 0 \) such that for all \( n \in \mathbb{N} \), \( 0 < t \leq 1 \) and \( 0 < x \) we have

\[
\left| \int^\infty_x h(t, s_1) \int^\infty_{s_1} h(t, s_2) \cdots \int^\infty_{s_{n-1}} h(t, s_n) \, ds_n \cdots ds_1 \right|
\]

\[
- \int^\infty_x \tilde{h}(s_1) \int^\infty_{s_1} \tilde{h}(s_2) \cdots \int^\infty_{s_{n-1}} \tilde{h}(s_n) \, ds_n \cdots ds_1
\]

\[
\leq C_6 \left( 1 + \frac{t}{x^2} \right)^{n-1} \left( 1 + \frac{1}{x} \right) \left( \frac{\sqrt{t}}{x} + t \right),
\]

with

\[
C_6 = C(\|u_1\|_{X^{\gamma, +}} + \|\partial_x u_1\|_{X^{\gamma, +}} + \|\partial_x^2 u_1\|_{X^{\gamma, +}}).
\]

Moreover, any occurrence of \( h \) can be replaced by \( \tilde{h} \), provided that the correspondent \( h \) is replaced by \( \tilde{h} \).

**Proof.** Lemma 3.4 with \( g(s) = 1 \) gives the Lemma for \( n = 1 \), by choosing \( C > \tilde{C} \). For \( n \geq 2 \) we shall proceed by recursion, with a constant \( C \)

\[
C = \max \{ 1, \tilde{C}, 3cC(a) + \tilde{C} \},
\]

where \( \tilde{C} \) stands for the constant of Lemma 3.2, \( c \) stands for the constant in Cauchy-Schwarz inequality and \( C(a) \) is used in

\[
\|f_+\|_{H^1} \leq C(a)(\|u_1\|_{X^{\gamma, +}} + \|\partial_x u_1\|_{X^{\gamma, +}}).
\]

We write the difference in (43) as

\[
\int^\infty_x \tilde{h}(s_1) \left( \int^\infty_{s_1} h(t, s_2) \cdots \int^\infty_{s_{n-1}} h(t, s_n) \, ds_n \cdots ds_1 \right) - \int^\infty_x \tilde{h}(s_2) \cdots \int^\infty_{s_{n-1}} \tilde{h}(s_n) \, ds_n \cdots ds_1
\]

\[
+ \int^\infty_x (h(t, s_1) - \tilde{h}(s_1)) \int^\infty_{s_1} h(t, s_2) \cdots \int^\infty_{s_{n-1}} h(t, s_n) \, ds_n \cdots ds_1 = I_1(t, x) + I_2(t, x).
\]
By the recursion hypothesis
\[ |I_1(t, x)| \leq \|f_0\|_{L^1} C_0^{n-1} \left( 1 + \frac{t}{x^2} \right)^{n-2} \left( 1 + \frac{1}{x} \right) \left( \frac{\sqrt{t}}{x} + t^{\frac{1}{\gamma}} \right). \]
\[ \leq \frac{c C(a)}{C} C_0^{n} \left( 1 + \frac{t}{x^2} \right)^{n-2} \left( 1 + \frac{1}{x} \right) \left( \frac{\sqrt{t}}{x} + t^{\frac{1}{\gamma}} \right). \]

Let us denote now
\[ f_n(t, x) = \int_x^\infty h(t, s_1) \int_{s_1}^\infty h(t, s_2) \cdots \int_{s_{n-1}}^\infty h(t, s_n) \, ds_n \cdots ds_1, \quad f_0(t, x) = 1. \]
We apply (42) to get
\[ |I_2(t, x)| = \left| \int_x^\infty (h(t, s_1) - \bar{h}(s_1)) f_{n-1}(t, s_1) \, ds_1 \right| \]
\[ \leq C_0(\|f_{n-1}(t)\|_{L^\infty(x, \infty)} + \| \partial_s f_{n-1}(t) \|_{L^1(x, \infty)}) \left( \frac{\sqrt{t}}{x} + t^{\frac{1}{\gamma}} \right). \]

Lemma 3.2 with \( f(t, s) = 1 \) gives us for \( k \geq 1 \)
\[ \|f_k(t)\|_{L^\infty(x, \infty)} \leq \hat{C}^k \|u(1/t)\|_{H^1} \left( 1 + \frac{t}{x^2} \right)^{\frac{k}{x}}. \]
Since
\[ |\partial_s f_{n-1}(t, s)| = |h(t, s)f_{n-2}(t, s)| = \frac{2}{s \sqrt{t}} \left| (u_s) \left( \frac{1}{t} \right) \right| |f_{n-2}(t, s)|, \]
we obtain by Cauchy-Schwarz
\[ \| \partial_s f_{n-1}(t) \|_{L^1(x, \infty)} \leq 2C \hat{C}^{n-2} \|u(1/t)\|_{H^1} \lambda_{n-1} \frac{1}{x} \left( 1 + \frac{t}{x^2} \right)^{n-2}. \]

Therefore by using (46) and (47) in (45) we obtain
\[ |I_2(t, x)| \leq \left( 1 + \frac{2C}{C} \right) \hat{C}^{n-1} \|u(1/t)\|_{H^1} \lambda_{n-1} C_0 \left( 1 + \frac{t}{x^2} \right)^{n-1} \left( 1 + \frac{1}{x} \right) \left( \frac{\sqrt{t}}{x} + t^{\frac{1}{\gamma}} \right) \]
\[ \leq \left( 1 + \frac{2C}{C} \right) \left( \frac{\hat{C} C(a)}{C} \right)^{n-1} \frac{C_0^{n}}{C} \left( 1 + \frac{t}{x^2} \right)^{n-1} \left( 1 + \frac{1}{x} \right) \left( \frac{\sqrt{t}}{x} + t^{\frac{1}{\gamma}} \right), \]
and the lemma follows also for \( n \geq 2 \) since choosing \( C > \hat{C} \) such that (44) holds implies
\[ \frac{c C(a)}{C} + \left( 1 + \frac{2C}{C} \right) \hat{C} C(a) \frac{C}{C} < 1. \]

**Proposition 3.6.** If \( u(1) \) and its first two derivatives are small in \( X^{\gamma} \) then for all \( x > 0 \) there exists a limit of \( T(t, x) \) at time \( t = 0 \),
\[ \lim_{x \to \infty} T(t, x) = T(0, x), \]
with the rate of convergence
\[ T(t, x) - T(0, x) = O(t^{\frac{1}{\gamma}}). \]
Moreover, for \( t \leq x^2 \)
\[ |T(t, x) - T(0, x)| \leq C_7(t, x), \]
where \( C_7(t, x) \) is a linear combination of powers \( \left( \frac{\sqrt{t}}{x} \right)^s \), \( 1 \leq s \leq 4 \).

**Proof.** – We fix \( 0 < x \). Let \( \tilde{a}_1(x) = T^\infty, \tilde{a}_2(x) = -3N^+ \int_x^\infty \tilde{h}(s)ds \) and for \( k \geq 1 \) set \( \tilde{a}_{2k+1}(x) \) to be

\[
(48) \quad (-1)^k \Re \int_x^\infty \tilde{h}(s_1) \int_{s_1}^\infty \tilde{h}(s_2) \cdots \Re \int_{s_{2k-2}}^\infty \tilde{h}(s_{2k-1}) \int_{s_{2k-1}}^\infty \tilde{h}(s_{2k}) T^\infty ds_{2k} \cdots ds_1,
\]

and \( \tilde{a}_{2k+2}(x) \) to be

\[
(49) \quad (-1)^{k+1} \Re \int_x^\infty \tilde{h}(s_1) \int_{s_1}^\infty \tilde{h}(s_2) \cdots \Re \int_{s_{2k-2}}^\infty \tilde{h}(s_{2k-1}) \int_{s_{2k-1}}^\infty \tilde{h}(s_{2k-2}) N^\infty \int_{s_{2k}}^{\infty} \tilde{h}(s_{2k+1}) ds_{2k+1} \cdots ds_1.
\]

Gathering Lemma 3.3 and Lemma 3.5 we can decompose

\[
(50) \quad T(t, x) = \sum_{j=1}^{2n} \tilde{a}_j(x) + R_n(t, x)
\]

with

\[
|R_n(t, x)| \leq C^{2n}\|u(1/t)\|_{L^1} 2^n (1 + a + \|u(1/t)\|_{L^2}) \left( 1 + \frac{t}{x^2} \right)^{2n} + C_5 \sum_{j=0}^{n-1} C^{2j}\|u(1/t)\|_{L^1} \left( 1 + \frac{t}{x^2} \right)^{2j} \left( \sqrt{t} + \frac{\sqrt{t}}{x} + \frac{t^2}{x^3} \right) + \sum_{j=1}^{2n-1} C_6^j \left( 1 + \frac{t}{x^2} \right)^{j-1} \left( 1 + \frac{1}{x} \right) \left( \sqrt{t} + \frac{t^2}{x} \right).
\]

Recall that

\[
\|u(1/t)\|_{L^1} \leq C(a) (\|u(1)\|_{X_{\gamma}^+} + \|u(1)\|_{X_{\gamma}^+}),
\]

and

\[
C_6 = C(\|u(1)\|_{X_{\gamma}^+} + \|u(1)\|_{X_{\gamma}^+} + \|u(1)\|_{X_{\gamma}^+}).
\]

Let \( t \leq x^2 \). Hence, \( u(1) \) and its first two derivatives are small in \( X_{\gamma}^+ \); it follows that there exists \( n(t, x) \) large enough such that for all \( n \geq n(t, x) \)

\[
|R_n(t, x)| \leq 2C_5 \left( \sqrt{t} + \frac{\sqrt{t}}{x} + \frac{t^2}{x^3} \right) + 2 \left( 1 + \frac{1}{x} \right) \left( \sqrt{t} + \frac{t^2}{x} \right).
\]

Note also that

\[
|\tilde{a}_j(x)| \leq C^{2j}\|f_+\|_{L^1}^2 \leq C^{2j} C(a)^{2j} (\|u(1)\|_{X_{\gamma}^+} + \|u(1)\|_{X_{\gamma}^+})^2.
\]

Therefore, there exists \( \tilde{n}(t, x) \geq n(t, x) \) large enough such that

\[
|R_{\tilde{n}(t, x)}(t, x)| + \sum_{j=2\tilde{n}(t, x)}^{\infty} \tilde{a}_j(x) \leq 3C_5 \left( \sqrt{t} + \frac{\sqrt{t}}{x} + \frac{t^2}{x^3} \right) + 3 \left( 1 + \frac{1}{x} \right) \left( \sqrt{t} + \frac{t^2}{x} \right).
\]

From (50) we get then

\[
T(t, x) - \sum_{j=1}^{\infty} \tilde{a}_j(x) = O(t^\frac{2}{x}).
\]
and the first part of the Proposition follows taking $T(0, x) = \sum_{j=1}^{\infty} \tilde{a}_j(x)$ and by letting $t$ go to 0.

Now we shall get some extra-information on $T(0, x)$. Note that in view of the definition of the $\tilde{a}_j$ (48)-(49) we deduce that for $f_+$ small enough in $H^1$,

\[
\|T(0)\|_{L^\infty} < \sum_{j=1}^{\infty} C^{2j} \|f_+\|_{H^1}^{2j} < \infty,
\]

\[
\|T_x(0)\|_{L^1} + \|T_x(0)\|_{L^2} \leq \|f_+\|_{H^1} \sum_{j=1}^{\infty} C^{2j} \|f_+\|_{H^1}^{2j} < \infty.
\]

We get also that for fixed $x > 0$ the complex vector $\tilde{N}(t, x)$ has a limit as $t \to 0$ in the following way. From Proposition 3.1 we have

\[
\tilde{N}(t, x) - N^\infty - i \int_x^\infty \tilde{h}(t, s) T(t, s) \, ds = \Theta(\sqrt{t}).
\]

We have proved above that $T(t, x) = T(0, x) + \Theta(t^{1/2})$. Take $\epsilon > 0$ and recall the bound (34). Then there exists $M_\epsilon$ large enough such that for $M \geq M_\epsilon$

\[
|\tilde{N}(t, x) - N^\infty - i \int_x^M \tilde{h}(t, s) T(t, s) \, ds| \leq \Theta(t^{1/2}) + \epsilon.
\]

Secondly, $T(0) \in L^\infty$ and $T_x(0) \in L^1$, so we can apply Formula (42) with $g(s) = T(0, s)$ to obtain

\[
|\tilde{N}(t, x) - N^\infty - i \int_x^M \tilde{h}(s) T(0, s) \, ds| \leq \Theta(t^{1/2}) + \epsilon.
\]

Now, since $\tilde{h} \in L^1$ and $T(0) \in L^\infty$, by choosing $M$ large enough we get

\[
|\tilde{N}(t, x) - N^\infty - i \int_x^\infty \tilde{h}(s) T(0, s) \, ds| \leq \Theta(t^{1/2}) + \epsilon.
\]

As a conclusion, there exists a limit of $\tilde{N}(t, x)$ as $t$ tends to 0 and

\[
(51) \quad \tilde{N}(0, x) = N^\infty + i \int_x^\infty \tilde{h}(s) T(0, s) \, ds.
\]

So in particular $\tilde{N}(0) \in L^\infty$ and $\tilde{N}_x(0) \in L^1 \cap L^2$, and we can argue similarly for $T$ to get

\[
(52) \quad T(0, x) = T^\infty - \Im \int_x^\infty \tilde{h}(s) \tilde{N}(0, s) \, ds.
\]

Gathering (51) and (52) we obtain an integral equation for $T(0)$ :

\[
(53) \quad T(0, x) = T^\infty - \Im \int_x^\infty \tilde{h}(s) \tilde{N}(0, s) \, ds - \Re \int_x^\infty \tilde{h}(s) \int_s^\infty \tilde{h}(s') T(0, s') \, ds' \, ds.
\]

Then the last estimate of the Proposition follows as in the proof of Proposition 4.6 in [4] by using (29)-(30)-(31), Lemma 3.2 and Lemma 3.4.

\[\square\]
3.3. Properties of the trace at time \( t = 0 \)

From (51) and (52) we obtain
\[
T_x(0, x) = \Im \left( \tilde{h}(x) \tilde{N}(0, x) \right), \quad \tilde{N}_x(0, x) = -i\bar{h}(x) T(0, x).
\]

We recall now that
\[
\tilde{h}(x) = i\hat{f}_+ \left( \frac{x}{2} \right) e^{-ia^2 \log |x|}.
\]

As a conclusion we have that \((T(0), \tilde{N}(0))\) satisfy
\[
\begin{cases}
T_x(0, x) = \Re \left( \hat{f}_+ \left( \frac{x}{2} \right) e^{-ia^2 \log |x|} \tilde{N}(0, x) \right), \\
\tilde{N}_x(0, x) = -\hat{f}_+ \left( \frac{x}{2} \right) e^{-ia^2 \log |x|} T(0, x).
\end{cases}
\]

Moreover, it was shown in §5 of [4], without using any weight condition, that there exists a rotation \( R \) such that
\[
RT(0, 0^\pm) = A^\pm, \quad R\tilde{N}(0, 0^\pm) = B^\pm.
\]

Finally, since
\[
f_+ = \mathcal{F}^{-1} \left( g(2\cdot)e^{i\alpha \log |2\cdot|} \right),
\]

it follows that \( \tilde{h}(x) = ig(x) \) so the traces \((T_0, \tilde{N}_0)\) given in (27) and \((RT(0), R\tilde{N}(0))\) coincide, since they are both solutions to (54) with same initial value. We recall that we have constructed \( \chi(t) \) with \( \chi(0, 0) = \chi_0(0) = 0 \). Now we have obtained also that \( R\partial_x \chi(0, x) = RT(0, x) = T_0(x) \) so we get that \( R\chi \) has trace \( \chi_0 \). Therefore we have constructed the solution of the statement of Theorem 1.2 for positive times.

3.4. Continuation through time \( t = 0 \)

We denote \( \chi_0^*(x) = \chi(0, -x) \). Then
\[
T_0^*(x) = -T(0, -x),
\]

and we define \( g^* \) and \( N_0^* \) given by the system
\[
\begin{cases}
T_0^* = \Re g^* \tilde{N}_0^*, \\
N_0^* = -\tilde{g}^* T_0^*.
\end{cases}
\]

with initial data \( \rho(A^+, B^+) \) for \( x > 0 \) and \( \rho(A^-, B^-) \) for \( x < 0 \). Note that in view of Proposition 2.2, the initial data for \( T_0^* \) makes sense. Also in view of Proposition 2.2, \( \rho A^\pm = R^\pm (-A^\mp) \) and \( \rho B^\pm = R^\pm B^\mp \) so the solution of (55) can be expressed in terms of the initial one (27),
\[
N_0^*(x) = R^\pm \tilde{N}_0(-x), \quad g^*(x) = g(-x).
\]

In particular, \( g^* \) satisfies the same conditions as \( g \), and we can apply Theorem 1.2 for positive times and initial data \( \chi_0^*(x) = \chi(0, -x) \). This yields \( \chi^*(t, x) \) solution of the binormal flow for positive times obtained with initial data \( \chi(0, -x) \). Then for negative times we shall extend \( \chi(t, x) \) by
\[
\chi(t, x) = \chi^*(-t, -x)
\]

and obtain the solution in Theorem 1.2 on \([-1, 1]\).
3.5. Uniqueness of the solution

For proving the uniqueness, suppose that there exists another solution \( \chi^* \) of the binormal flow on positive times, such that \( \chi^*(0) = \chi_0 \), with the following regularity. We suppose \( \chi^* \in \mathcal{C}([-1, 1], \mathcal{L}ip) \cap \mathcal{C}([-1, 1] \setminus \{0\}, \mathcal{C}^{4\gamma}) \) and assume that its filament functions associated at times \( \pm 1 \) are of the type \( (a + u^*(\pm 1, x))e^{i \frac{\pi}{2} x} \) with \( u^*(\pm 1) \) small in \( X^\gamma_T \cap H^4 \) with respect to \( a \) for some \( 0 < \gamma < \frac{1}{4} \). We shall prove that \( \chi^* = \chi \) on positive time (the same argument applied to \( \chi(-t, -x) \) and \( \chi_0(-x) \) will show the uniqueness for negative times).

In view of the scattering result from [3] we denote \( u^*(t, x) \) to be the solution of (10) with initial data at time \( t = 1 \) the function \( u^*(1) \), and we denote by \( f^*_t \) its asymptotic state. Since

\[
|\chi_x^* \wedge \chi_{xx}^*(\tau, x)| = |e^* b^*(\tau, x)| = \frac{1}{\sqrt{t}}|(a + u^*)\left(\frac{1}{t}, \frac{x}{t}\right)| \leq \frac{C}{\sqrt{t}},
\]

we can write the Duhamel formula from time 0 to a positive time \( t \)

\[
\chi^*(t, x) = \chi_0(x) + \int_0^t \chi_x^* \wedge \chi_{xx}^*(\tau, x) d\tau.
\]

Differentiating in \( x \) we obtain a formulation for the tangent vector, at \( x \neq 0 \),

\[
T^*(t, x) = T_0(x) + \partial_x \int_0^t \chi_x^* \wedge \chi_{xx}^*(\tau, x) d\tau.
\]

We define \( g^* \) by \( f^*_t = \mathcal{F}^{-1}\left(g(2^t e^{itx \log |2^t|})\right) \). From [4], together with the computations in the previous Subsections 3.1–3.3 for avoiding weighted conditions on the data, we have that the tangent vector \( T^*(t, x) \) has a limit \( T^*(0, x) \) as \( t \) goes to zero, for \( x \neq 0 \). We also get the existence of a \( C^2\)-valued function \( \tilde{N}^* \) orthonormal on \( T^*(0) \) such that for \( x > 0 \)

\[
\begin{cases}
T_x^*(0, x) = \Re(g^*(x)\tilde{N}^*(x)), \\
\tilde{N}^*_x(x) = -\overline{g^*(x)}T^*(0, x),
\end{cases}
\]

with initial data \( (A^+, B^+) \) (and similar for \( x < 0 \)). Since \( T^* \) is a solution of the Schrödinger map (2) we can write for \( 0 < \tilde{t} < t \),

\[
T^*(t, x) = T^*(\tilde{t}, x) + \int_{\tilde{t}}^{t} T^* \wedge T^*_{xx}(\tau, x) d\tau = T^*(\tilde{t}, x) + \int_{\tilde{t}}^{t} \chi_x^* \wedge \chi_{xx}^*(\tau, x) d\tau.
\]

Let \( \phi \) be a compactly supported test function away from \( x = 0 \), such that \( \phi' \in L^1 \). Then by integrating by parts,

\[
\int T^*(t, x) \phi(x) dx = \int T^*(\tilde{t}, x) \phi(x) dx - \int_{\tilde{t}}^{t} \chi_x^* \wedge \chi_{xx}^*(\tau, x) d\tau \phi'(x) dx.
\]

Then, in view of (58) we obtain

\[
\int (T_0(x) - T^*(0, x)) \phi(x) dx = \int (T^*(\tilde{t}, x) - T^*(0, x)) \phi(x) dx + \int_{\tilde{t}}^{t} \chi_x^* \wedge \chi_{xx}^*(\tau, x) d\tau \phi'(x) dx.
\]

Using Proposition 3.6 and (56) we obtain

\[
\int (T_0(x) - T^*(0, x)) \phi(x) dx = 0.
\]

ANNALES SCIENTIFIQUES DE L’ÉCOLE NORMALE SUPÉRIEURE
Since $\partial_x T^*(0, x) \in L^1 \cap L^2$ we obtain that $T^*(0, x)$ is continuous for $x \neq 0$. The same is valid for $T_0(x)$. By taking $\phi$ approximating the Dirac distribution located at $x \neq 0$ we obtain that $T^*(0, x) = T_0(x)$. Therefore using (59) and (27) we get
\[(\Re N_0 - \Re N^*)(x) = \int_0^x - (\Re g - \Re g^*)(y) T_0(y) = - \int_0^x (T_{0x}, (\Re N_0 - \Re N^*)) T_0(y) dy\]
so by using again (27) and Cauchy-Schwarz inequality
\[
\left| (\Re N_0 - \Re N^*)(x) \right| \leq C \int_0^x |g(y)|| (\Re N_0 - \Re N^*)(y)| dy
\]
\[
\leq C \| f_+ \|_{L^2} \left( \int_0^x | (\Re N_0 - \Re N^*)(y) |^2 dy \right)^{\frac{1}{2}}.
\]
We conclude by Gronwall that $\Re N_0 = \Re N^*$. Similarly we obtain $\Im N_0 = \Im N^*$, so $N_0 = N^*$. Therefore we get $g = g^*$, and implicitly $f_+ = f_+^*$. From [3] we have uniqueness of the wave operators, so $u(t, x) = u^*(t, x)$. Therefore curvature and torsion are the same for $\chi^*$ and $\chi$, so $\chi^*$ and $\chi$ are the same modulo one rotation (due to the choice of an initial data for the Frenet frame when integrating the Frenet system to obtain the Frenet frame) and one translation (due to the choice of the location of the curve when integrating the binormal flow to obtain the binormal solution). Since the initial data $\chi^*(0)$ and $\chi(0)$ coincide as oriented curves, it follows that $\chi^*$ and $\chi$ coincide.

### 3.6. Properties of the solution

Recall that by using the Frenet system, the binormal flow (1) can be written as
\[
\chi_t = c b.
\]
The estimate (14) in part i) of Theorem 1.2 follows from the fact that the solution $u(t)$ is small, so the curvature is close to the one of the selfsimilar solutions $c_a(t', x) = \frac{a}{\sqrt t}$,
\[
|\chi(0, x) - \chi_0(x)| \leq \int_0^t |\chi_x(t', x) dt'| = \left| \int_0^t c(t', x) b(t', x) dt' \right| \leq \int_0^t c(t', x) dt' \leq C \sqrt t.
\]
To prove ii) we shall use the notations in §2 of [4] on parallel frames:
\[
\chi_t = T \wedge T_x = T \wedge (ae_1 + \beta e_2) = \alpha e_2 - \beta e_1 = \Im(\bar{u} N),
\]
so integrating between two fixed times $0 < t_2 \leq t_1 \leq 1$ we obtain
\[
\chi(t_1, x) - \chi(t_2, x) = \int_{t_2}^{t_1} \Im(\bar{u} N)(t, x) dt = \Im \int_{t_2}^{t_1} \frac{e^{-i \frac{\pi}{2} t^2}}{\sqrt t} \left( a + u \left( \frac{1}{\sqrt t}, \frac{1}{t} \right) \right) N(t, x) dt.
\]
We perform an integration by parts from the oscillating phase,
\[
\chi(t_1, x) - \chi(t_2, x) = \Im \left[ 4t^2 \frac{e^{-i \frac{\pi}{2} x^2}}{ix^2} \left( a + u \left( \frac{1}{\sqrt t}, \frac{1}{t} \right) \right) N(t, x) \right]_{t_2}^{t_1} + \frac{1}{x^2} \Re \int_{t_2}^{t_1} e^{-i \frac{\pi}{2} x^2} \partial_t \left( 4t \sqrt t (a + u) \left( \frac{1}{\sqrt t}, \frac{1}{t} \right) N(t, x) \right) dt.
\]
Since \( N_t = i\psi T - \frac{a^2 - t|\psi|^2}{x} N \) and \( u \) solves (10) it follows that
\[
|\chi(t_1, x) - \chi(t_2, x)| \leq C \frac{t_1 \sqrt{t_1}}{x^2} (a + \|u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)}) \\
+ C \frac{\sqrt{t_1}}{x^2} \|\partial_x^2 u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)} \\
+ C(a) \frac{1}{x^2} \left( \|u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)} + \|u(1/t)\|_{L_\infty}^3 \right) \\
+ C \frac{\sqrt{t_1}}{x} \|\partial_x u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)} \\
+ C \frac{t_1}{x} (a + \|u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)})^2 \\
+ C \frac{t_1}{x} (a + \|u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)}) \|\partial_x u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)} \\
+ C(a) \frac{t_1 \sqrt{t_1}}{x^2} (a + \|u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)}) \\
\times \left( \|u(1/t)\|_{L^\infty([t_2, t_1], L^\infty)} + \|u(1/t)\|_{L_\infty}^2 \right).
\]

In view of (28) the first asymptotic behavior (15) in ii) follows. The second asymptotic behavior in ii) was proved in §3.2 of [4], and (16) was displayed in Proposition 3.1.

Let us prove (iii). On one hand, as done above for proving (14) we get
\[
\left| \int_{-1}^1 \chi(t, x) \phi(t, x) \, dx \right| \leq C \|\phi\|_{L^1} \int_{-1}^1 \frac{1}{\sqrt{|t|}} \, dt < \infty.
\]

On the other hand \( \chi \) is a strong solution of (1) on \([-1, 0]\cap[0, 1]\), so (17) of iii) follows also.

Estimate (18) comes from Proposition 3.6, and the fact that \( \partial_x T(0) \in L^1 \cap L^2 \) was proved at the beginning of §3.3, so the assertions in iv) are proved.

Finally, v) follows immediately from (17). The proof of Theorem 1.2 is complete.

4. Proof of Theorem 1.3

Concerning Theorem 1.3 we recall that its part concerning positive times \( t \geq 0 \) was the main result in [4], under the assumption that weighted conditions are satisfied by \( u(1) \). In the proof of Theorem 1.2 we have removed these conditions, provided that the initial data (or the asymptotic state) are small in spaces of type \( \partial_x^k f \in X^\gamma \) for \( 0 \leq k \leq 4 \) and some \( \gamma < \frac{1}{2} \). For extending \( \chi \) to negative times, we proceed as explained above in §3.4.

5. Appendix: Analysis in weighted spaces of the NLS equation

We recall that the results in this paper could have been obtained easily from [3], provided that the initial state \( u(1) \) of Equation (10) is in weighted spaces implies that its asymptotic state \( f_+ \) belongs also to weighted spaces and reciprocally. We shall present here a detailed analysis of the solutions of the linear part of (10) whose data belong to weighted spaces. As a conclusion, weighted spaces are not an appropriate setting for scattering theory of Equation (10), that actually is in contrast with the case of the classical linear Schrödinger equation.
We set \( \omega(t) = S(t, t_0)\omega(t_0) \) to be the solution of
\[
\frac{i}{2} \omega_t + \omega_{xx} + \frac{a^2}{2t} (\omega + \overline{\omega}) = 0,
\]
with initial data \( \omega(t_0) \) at time \( t_0 \). We set then \( v(t) = J(t)\omega(t) = (x + 2it\nabla)\omega(t) \), which satisfies
\[
i v_t + v_{xx} + \frac{a^2}{2t}(v + \overline{v}) = \frac{a^2}{2t} (J\omega - J\bar{\omega}) = -2ia^2\overline{v}_x,
\]
with initial data \( v(t_0) = J(t_0)\omega(t_0) \) at time \( t_0 \). Taking the real and imaginary parts, and then passing in Fourier variables yields
\[
\partial_t \hat{v}(t, \xi) = \xi^2 \hat{v}(t, \xi) - 2ia^2\xi \hat{\omega}(t, \xi),
\]
\[
\partial_t \hat{\omega}(t, \xi) = -\xi^2 \hat{v}(t, \xi) + \frac{a^2}{t} \hat{\omega}(t, \xi) + 2ia^2\xi \hat{\omega}(t, \xi).
\]

In the rest of this appendix we shall try to understand how the \( L^2 \) norm of \( v(t) = J(t)\omega(t) \) grows in time. First, recall that the classical linear Schrödinger equation commutes with \( J(t) \). We have the following result.

**Proposition 5.1.** For \( \xi \neq 0 \) the evolution of \( J(t)\omega(t) \) is described by
\[
J(t)\omega(t) = S(t, 1)J(1)\omega(1) + S(t, 1)J^{-1} \left( \frac{2a^2}{\xi} \hat{\omega}(1, \xi) \right) - J^{-1} \left( \frac{2a^2}{\xi} \hat{\omega}(t, \xi) \right).
\]

**Proof.** From (62) we deduce that we can write
\[
\hat{\omega} = \hat{\omega}(t) + \frac{i}{2} \partial_t \hat{v}(t, \xi) - \frac{2a^2}{\xi} \hat{\omega}(t, \xi).
\]

Let us recall that since \( \omega \) solves (60), it follows that
\[
\partial_t \hat{\omega}(t, \xi) = \xi^2 \hat{\omega}(t, \xi).
\]

Gathering this with (62) and (63) we obtain that \( \hat{\omega}(t, \xi) \) satisfies the second order equation
\[
\partial_t^2 f(t, \xi) = \xi^2 \left( -\xi^2 + \frac{a^2}{t} \right) f(t, \xi),
\]
with initial data
\[
f(1, \xi) = \hat{\omega}(1, \xi), \quad \partial_t f(1, \xi) = \xi^2 \hat{v}(1, \xi) = 2ia^2\xi \hat{\omega}(1, \xi).
\]

Now we notice that if \( f(t, \xi) \) is a solution of (65) with initial data that satisfies
\[
f(1, \xi) = f(1, -\xi), \quad \partial_t f(1, \xi) = \partial_t f(1, -\xi),
\]
then this property is conserved in time, and we have the identity
\[
f(t, \xi) + i \frac{\partial_t f(t, \xi)}{\xi^2} = J S(t, 1) J^{-1} \left( f(1, \xi) + i \frac{\partial_t f(1, \xi)}{\xi^2} \right).
\]

This is valid since both functions satisfy the equation of the Fourier transform of a \( S(t, 1) \) evolution (see (60)):
\[
i U_t(t, \xi) - \xi^2 U(t, \xi) + \frac{a^2}{2t} (U(t, \xi) + \overline{U(t, \xi)}) = 0,
\]
with the same initial data.
Finally, since the initial condition (66) satisfies the condition (67) it follows that
\[
\hat{R}v + i \frac{\partial \hat{R}v}{\partial \xi} = \mathcal{J} S(t, 1) \mathcal{J}^{-1} \left( v(1)(\xi) + \frac{2a^2}{\xi} \hat{R} \omega(1, \xi) \right),
\]
so in view of (64) the proof is complete. \[\square\]

So first we shall see in the next Proposition that imposing vanishing condition at the zero-modes on the asymptotic state we obtain that the solution belongs to weighted spaces. Let us recall the asymptotic results obtained in §2.1 of [3] for \( \hat{\omega} \) with \( \omega \) the solution of (60). For \( 4a^2 \leq t \xi^2 \) we denoted
\[
\left( \begin{array}{c} \hat{R}w \\ 3w \end{array} \right)(t, \xi) = \left( \begin{array}{c} Y \\ Z \end{array} \right)(t \xi^2, \xi) = \left( \begin{array}{cc} e^{i \Phi(t \xi^2)} & e^{-i \Phi(t \xi^2)} \\ i \alpha(t \xi^2) e^{i \Phi(t \xi^2)} & -i \alpha(t \xi^2) e^{-i \Phi(t \xi^2)} \end{array} \right) \left( \begin{array}{c} Y_2 \\ Z_2 \end{array} \right)(t \xi^2, \xi),
\]
with
\[
\alpha(\tau) = \sqrt{1 - \frac{a^2}{\tau}}, \quad \Psi(\tau) = \tau - \frac{a^2}{2} \log \tau - \int_\tau^\infty \alpha(s) - 1 + \frac{a^2}{2s} ds.
\]
We proved that for \( \tau \leq 4a^2 \)
\[
\partial_\tau \left( \begin{array}{c} Y_2 \\ Z_2 \end{array} \right)(\tau, \xi) = M(\tau) \left( \begin{array}{c} Y_2 \\ Z_2 \end{array} \right)(\tau, \xi),
\]
with
\[
M(\tau) = \frac{a^2}{4 \tau^2 \alpha^2} \left( \begin{array}{cc} -1 & e^{-2i \Phi(\tau)} \\ e^{2i \Phi(\tau)} & -1 \end{array} \right),
\]
and that \( (Y_2, Z_2)(\tau, \xi) \) has a limit \( (Y^+, Z^+)(\xi) \) as \( \tau \) goes to infinity. Moreover, we obtained
\[
\lim_{t \to \infty} \left( \hat{\omega}(t)(\xi) - 2 e^{-it \xi^2} e^{i \xi^2 \log t u_+}(\xi) \right) = 0,
\]
with
\[
Y^+(\xi) = \frac{1}{2} e^{-ia^2 \log |\xi|} u_+^-(\xi), \quad Y^+(\xi) = \frac{1}{2} e^{ia^2 \log |\xi|} u_+^+(\xi).
\]
For \( J(t) \omega(t) \) we shall use all this information in order to prove the following result.

**Proposition 5.2.** – The solution \( \omega \) of the linear Equation (60) satisfies for \( t \xi^2 \geq 2a^2 \) that
\[
|J(t) \omega(t)(\xi)| \leq C(a) \frac{1}{\xi} (|u_+^-(\xi)| + |u_+^+(-\xi)|)
\]
and for \( t \xi^2 \leq 2a^2 \) that
\[
|J(t) \omega(t)(\xi)| \leq C(a) \frac{1}{\xi} (|u_+^-(\xi)| + |u_+^+(-\xi)|) + C(a, \delta) \frac{1}{\xi^{1+\delta}} (|u_+^+(\xi)| + |u_+^+(-\xi)|).
\]
Therefore
\[
\|J(t) \omega(t)\|_{L^2} \leq C(a) \|u_+\|_{H^{-1}} + C(a, \delta) \|u_+\|_{H^{-1-\delta}}.
\]
\textbf{Proof.} – Following the first lines of the proof of Proposition A.1 in [3] (using the notations therein), the same way we have obtained for $4a^2 \leq \tau$

$$|Y_2(\tau, \xi)|^2 + |Z_2(\tau, \xi)|^2 \leq C(|\hat{u}_+(\xi)|^2 + |\hat{u}_+(-\xi)|^2)$$

we also obtain

$$|\partial_\xi Y_2(\tau, \xi)|^2 + |\partial_\xi Z_2(\tau, \xi)|^2 \leq C(|\partial_\xi (e^{-ia^2 \log \xi^2 \hat{u}_+ (\xi)})|^2 + |\partial_\xi (e^{-ia^2 \log \xi^2 \hat{u}_+ (-\xi)})|^2).$$

For $4a^2 \leq \tau^2$ we use (69) to get

$$J(t)\hat{w}(t)(\xi) = (i\partial_\xi - 2t\xi)\hat{w}(t, \xi) = (i\partial_\xi - 2t\xi) ((1 - \alpha) e^{i\Phi} Y_2 + (1 + \alpha) e^{-i\Phi} Z_2) (t\xi^2, \xi).$$

For any function $f$ we compute by using $\partial_\alpha \Phi = \alpha$ and $\partial_\tau \alpha = \frac{a^2}{2\tau^2}$,

$$\begin{align*}
(i\partial_\xi - 2t\xi) \left( (1 - \alpha(t\xi^2)) e^{i\Phi(it\xi^2)} f(\xi) \right) &= i(1 - \alpha)e^{i\Phi}\partial_\xi f - \frac{2a^2}{\xi}e^{-i\Phi} f - \frac{ia^2}{\alpha t\xi^2} e^{i\Phi} f, \\
(i\partial_\xi - 2t\xi) \left( (1 + \alpha(t\xi^2)) e^{-i\Phi(it\xi^2)} f(\xi) \right) &= i(1 + \alpha)e^{-i\Phi}\partial_\xi f - \frac{2a^2}{\xi}e^{-i\Phi} f + \frac{ia^2}{\alpha t\xi^2} e^{-i\Phi} f.
\end{align*}$$

In particular

$$J(t)\hat{w}(t)(\xi) = i (1 - \alpha) e^{i\Phi}\partial_\xi Y_2 + i2t\xi (1 - \alpha) e^{i\Phi}(M_{11} Y_2 + M_{12} Z_2) - \frac{2a^2}{\xi}e^{-i\Phi} Y_2 - \frac{ia^2}{\alpha t\xi^2} e^{i\Phi} Y_2 + i(1 + \alpha) e^{-i\Phi}\partial_\xi Z_2 + i2t\xi (1 + \alpha) e^{-i\Phi}(M_{21} Y_2 + M_{22} Z_2) - \frac{2a^2}{\xi}e^{-i\Phi} Z_2 + \frac{ia^2}{\alpha t\xi^2} e^{-i\Phi} Z_2.$$

By using the exact expression of $M$ we obtain that

$$J(t)\hat{w}(t)(\xi) = \frac{2a^2}{\xi} \left( e^{i\Phi} Y_2 + e^{-i\Phi} Z_2 \right) + i (1 - \alpha) e^{i\Phi}\partial_\xi Y_2 + i(1 + \alpha) e^{-i\Phi}\partial_\xi Z_2.$$

In conclusion in the present region $2a^2 \leq \tau^2$ we have

$$\sup_{2a^2 \leq \tau^2} |\hat{v}(t, \xi)| \leq \frac{C}{\xi} (|\hat{u}_+(\xi)| + |\hat{u}_+(-\xi)|) + C(|\partial_\xi (e^{-ia^2 \log \xi^2 \hat{u}_+ (\xi)})|^2 + |\partial_\xi (e^{-ia^2 \log \xi^2 \hat{u}_+ (-\xi)})|^2)$$

$$\leq \frac{C}{\xi} (|\hat{u}_+(\xi)| + |\hat{u}_+(-\xi)|).$$

so in particular

$$\|\hat{v}(t)\|_{L^2(\xi^2 \geq \frac{1}{t^2})} \leq C\sqrt{T} \|u_+\|_{L^2}.$$

For the cases $\tau^2 \leq 2a^2$ we can use energy methods like in Proposition A.1 in [3] to connect(1) the time $t_1 = \tau$ to the time $t_2 = \frac{2a^2}{\xi^2}$ which in turn connects to the asymptotic state via (74), and it is in here that we encounter the $H^{-1}$ space

$$|\hat{v}(t, \xi)| \leq C(a) |\hat{v}(\frac{2a^2}{\xi^2}, \xi)| + |\hat{v}(\frac{2a^2}{\xi^2}, -\xi)|$$

$$+ C(a, \delta_1, \delta_2) \left( \frac{2a^2}{\xi^2} + \delta_1 + \delta_2 \right) \left( \left| \hat{w}(\frac{2a^2}{\xi^2}, \xi) \right| + \left| \hat{w}(\frac{2a^2}{\xi^2}, -\xi) \right| \right).$$

(1) It is also possible to derive backwards pointwise Fourier estimates in the spirit of [4].
Using (74) and Remark A.2. from [3] we conclude that
\[
|\hat{v}(t, \xi)| \leq C(a) \frac{1}{\xi} (|\hat{u}_+ (\xi)| + |\hat{u}_+ (-\xi)|) + C(a, \delta) \frac{1}{\xi^{1+\varepsilon}} (|\hat{u}_+ (\xi)| + |\hat{u}_+ (-\xi)|),
\]
and the lemma follows. □

In the next proposition we give a precise result about the asymptotic behavior of \( J(t)w(t)(\xi) \) for \( \xi \neq 0 \) fixed.

**Proposition 5.3.** – For \( \xi \neq 0 \) we have the pointwise behavior
\[
\lim_{t \to \infty} \left( J(t)w(t)(\xi) - 2ie^{-i\hat{\Psi}(t\xi^2)} \partial_\xi Z^+ (\xi) + \frac{2a^2}{\xi} (e^{i\hat{\Psi}(t\xi^2)} Y^+ (\xi) + e^{-i\hat{\Psi}(t\xi^2)} Z^+ (\xi)) \right) = 0,
\]
where
\[
\hat{\Psi}(t\xi^2) = t\xi^2 - \frac{a^2}{2} \log t\xi^2.
\]

**Proof.** – We write
\[
J(t)w(t)(\xi) = (i\partial_\xi - 2t\xi) \left( (1 - \alpha(t\xi^2)) e^{i\Phi(t\xi^2)} Y^+ (\xi) + (1 + \alpha(t\xi^2)) e^{-i\Phi(t\xi^2)} Z^+ (\xi) \right)
\]
\[-(i\partial_\xi - 2t\xi) \left( (1 - \alpha) e^{i\Phi} \int_{-\infty}^{\infty} M_{11}Y_2 + M_{12}Z_2 + (1 + \alpha) e^{-i\Phi} \int_{-\infty}^{\infty} M_{21}Y_2 + M_{22}Z_2 \right)(t\xi^2).
\]
We denote \( I_1 \) the first term and \( I_2 \) the second. Since the entries of \( M(\tau) \) are upper-bounded by \( \frac{C(\alpha)}{\tau^2} \) it follows from (72) that
\[
|I_2(t, \xi)| \leq \frac{C(u_+)}{t\xi^3},
\]
so this term is negligible for the pointwise asymptotics in time. Using again (72) we obtain that
\[
|I_1(t, \xi) - i(1 - \alpha) e^{i\Phi} \partial_\xi Y^+ - i(1 + \alpha) e^{-i\Phi} \partial_\xi Z^+ + \frac{2a^2}{\xi} (e^{i\Phi} Y^+ + e^{-i\Phi} Z^+)| \leq \frac{C(u_+)}{t\xi^3}.
\]
We have \( \alpha(\tau) = \sqrt{1 - \frac{a^2}{\tau^2}} \), so
\[
|I_1(t, \xi) - 2ie^{-i\Phi} \partial_\xi Z^+ + \frac{2a^2}{\xi} (e^{i\Phi} Y^+ + e^{-i\Phi} Z^+)| \leq \frac{C(u_+)}{t\xi^3},
\]
and the statement of the proposition is proved, since \( \hat{\Psi}(\tau) = \Psi(\tau) + o(\frac{1}{\tau}) \). □

Using (71) and the above proposition we conclude that for \( J(t)w(t) \) to be uniformly in \( L^2 \) it is necessary that the asymptotic state \( \hat{u}_+ (\xi) \) has a null zero Fourier mode. This property is not preserved for solutions of the non-linear Equation (10), and therefore weighted spaces do not seem to be the right functional setting for Theorem 1.2 and Theorem 1.3.
