TRIVIAL COCYCLES AND INVARIANTS OF HOMOLOGY 3-SPHERES

WOLFGANG PITSCH

Abstract. We study the relationship between trivial cocycles on the Torelli group and invariants of oriented integral homology 3-spheres. We apply this study to give a new purely algebraic construction of the Casson invariant and prove in this setting its surgery properties. As a by-product we get a new 2-torsion cohomology class in the second integral cohomology of the Torelli group.

Introduction

If one tries to understand 3-manifolds by “cut and paste” techniques one faces two different paths: either one can concentrate the difficulties in the pieces and have “simple” glueing maps (see Kneser’s prime decomposition or Thurston decomposition into geometric pieces) or one can concentrate the difficulty into the glueing maps and get “simple” pieces. In the latter path one finds the theory of Heegaard splittings, the pieces are handlebodies and the glueing problems are encompassed within the mapping class groups of oriented surfaces, $\mathcal{M}_{g,1}$. It is natural then to try to construct invariants of 3-manifolds out of the algebraic properties of this groups. For general 3-manifolds this strategy has been adopted for instance by Birman in [2] but is usually hopelessly difficult, for the structure of $\mathcal{M}_{g,1}$ is quite involved. In this paper we will concentrate on the subclass of integral homology 3-spheres. In this case the group that controls the glueings is the Torelli group, $\mathcal{T}_{g,1}$. This approach has been that of Morita in [15] where he constructed a function out of the Torelli group that he showed to coincide point-wise with the Casson invariant. Although this did not succeed into a new construction of this important invariant it was the starting point for a fruitful exploration the interplay between the Casson invariant and algebraic properties of the Torelli group [15, 16, 17].

In this paper we will give a general framework to construct invariants of homology spheres in a purely algebraic setting. We will show that the algebraic problems boil down to a low-dimensional cohomological problem. As an example we will give a construction of an invariant of homology spheres and by proving the “surgery formulas” we will show that it coincides with the Casson invariant.

Denote by $\mathcal{V}(3)$ the set of diffeomorphism classes of compact, closed and oriented smooth 3-manifolds and by $\mathcal{S}(3) \subset \mathcal{V}(3)$ the subset of homology spheres, that is diffeomorphisms classes that have the same integral homology as the standard 3-sphere $S^3$. Let $\Sigma_g$ denote an oriented surface of genus $g$ standardly embedded in the

oriented 3-sphere $S^3$. In particular $\Sigma_g$ separates $S^3$ into two genus $g$ handlebodies $S^3 = H_g \cup -H_g$ with opposite induced orientation. Denote by $M_{g,1}$ the mapping class group of $\Sigma_g$, that is the group of orientation-preserving diffeomorphisms of $\Sigma_g$ which are the identity on a small fixed disc modulo isotopies which fix that small disc pointwise. The embedding $\Sigma_g \to S^3$ determines three natural subgroups of $M_{g,1}$, namely the subgroup $B_{g,1}$ of mapping classes that are restrictions of diffeomorphisms of the first handlebody $H_g$, the subgroup $A_{g,1}$ of mapping classes that are restrictions of diffeomorphisms of the second handlebody $-H_g$ and their intersection $AB_{g,1}$.

From the theory of Heegaard splittings we learn that any element in $V(3)$ can be obtained by cutting $S^3$ along $\Sigma_g$ for some $g$ and glueing back the two handlebodies by some element $\phi \in M_{g,1}$. The lack of injectivity of this construction is controlled by the subgroups $B_{g,1}$ and $A_{g,1}$. More precisely there is a natural injective stabilization map $M_{g,1} \to M_{g+1,1}$, which is compatible with the definitions of the above subgroups and one gets a well-defined bijective map:

$$\lim_{g \to \infty} B_{g,1} \backslash M_{g,1} / A_{g,1} \quad \sim \quad V(3)$$

$$\phi \quad \mapsto \quad S^3 = H_g \cup -H_g.$$

Thus any problem on 3-dimensional manifolds can be translated into a problem on the mapping class group. In particular any invariant $F : V(3) \to \mathbb{Z}$ can be viewed as a compatible family of functions on the mapping class groups $M_{g,1}$ which are constant on double cosets.

If we restrict our study to $S(3)$ the situation becomes more tractable. First we can restrict our attention to those mapping classes that act trivially on the homology of the underlying surface. Recall that the Torelli group $T_{g,1}$ is defined as the kernel of the natural map $M_{g,1} \to \text{Aut } (H_1(\Sigma_g; \mathbb{Z}))$. The above bijection induces a new bijection $[15]$:

$$\lim_{g \to \infty} B_{g,1} \backslash T_{g,1} / A_{g,1} \quad \sim \quad S(3)$$

$$\phi \quad \mapsto \quad S^3 = H_g \cup -H_g,$$

where $B_{g,1} \backslash T_{g,1} / A_{g,1}$ stands for those mapping classes in $M_{g,1}$ that contain an element of the Torelli group. Denote by $\mathcal{TB}_{g,1}$ (resp. $\mathcal{TA}_{g,1}$) the group $T_{g,1} \cap B_{g,1}$ (resp. $T_{g,1} \cap A_{g,1}$). The induced equivalence relation on the Torelli group has an intrinsic description:

**Theorem 1.** Two elements $\phi, \psi \in T_{g,1}$ are in the same double coset in $B_{g,1} \backslash M_{g,1} / A_{g,1}$ if and only if there exist maps $\xi_b \in \mathcal{TB}_{g,1}, \xi_a \in \mathcal{TA}_{g,1}$ and $\mu \in AB_{g,1}$ such that

$$\phi = \mu \xi_b \psi \xi_a \mu^{-1}.$$
trivial cocycles. One might wonder what conditions we should impose on a family \((C_g)\) of trivial 2-cocycles on the Torelli groups such that from their trivializations one can extract a family of compatible trivializations \((F_g)\) that reassemble into an invariant of homology spheres \(F : S(3) \to \mathbb{Z}\). Notice that the maps \(F_g\) are necessarily \(\mathcal{A}\mathcal{B}_{g,1}\)-invariant trivializations of the cocycles.

The cocycles \(C_g\) inherit the following properties of the maps \(F_g\):

1. The cocycles \(C_g\) are be compatible \(C_{g+1}|_{\mathcal{T}_{g,1} \times \mathcal{T}_{g,1}} = C_g\).
2. The cocycles \(C_g\) are 0 on \(\mathcal{T}B_{g,1} \times \mathcal{T}_{g,1} \cup \mathcal{T}_{g,1} \times \mathcal{T}A_{g,1}\).
3. The cocycles \(C_g\) are invariant under conjugation by \(\mathcal{A}\mathcal{B}_{g,1}\).

Then, the existence of an \(\mathcal{A}\mathcal{B}_{g,1}\)-invariant trivialization of the cocycle \(C_g\) is controlled by a cohomology class, the torsor:

\[\rho(C_g) \in H^1(\mathcal{A}\mathcal{B}_{g,1}; \wedge^3 H_1(\Sigma_g; \mathbb{Z}))\]

The three conditions above and the nullity of the torsor turn out to be not only necessary but also sufficient:

**Theorem 2.** A family of cocycles \((C_g)_{g \geq 3}\) on the Torelli groups \(\mathcal{T}_{g,1}\), \(g \geq 3\), satisfying conditions (1) – (3) provides a compatible family of trivializations \(F_g : \mathcal{T}_{g,1} \to \mathbb{Z}\) that reassemble into an invariant of homology spheres

\[\lim_{g \to \infty} F_g : S(3) \to \mathbb{Z}\]

if and only if the following two conditions hold:

1. The associated cohomology classes \([C_g] \in H^2(\mathcal{T}_{g,1}; \mathbb{Z})\) are trivial.
2. The associated torsors \(\rho(C_g) \in H^1(\mathcal{A}\mathcal{B}_{g,1}; \wedge^3 H_1(\Sigma_g))\) are trivial.

In this case the maps \(F_g\) are the unique \(\mathcal{A}\mathcal{B}_{g,1}\)-invariant trivializations of the cocycles \(C_g\).

Obviously, constructing (trivial) 2-cocycles directly on the Torelli group is still a difficult problem but instead one could try to pull-back known 2-cocycles defined on homomorphic images of the Torelli group. We successfully apply this strategy to the the Johnson homomorphism \(\tau : \mathcal{T}_{g,1} \to \wedge^3 H_1(\Sigma_g; \mathbb{Z})\).

**Theorem 3.** The unique 2-cocycles on \(H_1(\Sigma_g; \mathbb{Z})\) whose pull-back along the Johnson homomorphism satisfy conditions (1) – (3) are of the form \(nJ_g\), \(n \in \mathbb{Z}\) for an explicit 2-cocycle \(J_g\). Moreover:

1. The pull-backs of the cocycles \(2J_g\) and the associated torsors \(\rho(2J_g)\) are trivial.
2. The associated invariant is equal to the Casson invariant.

Moreover:

**Theorem 4.** 1) The pull-backs of the cocycles \(J_g\) on the Torelli groups are not trivial and define stable 2-torsion cohomology classes \([J_g] \in H^2(\mathcal{T}_{g,1}; \mathbb{Z})\).

2) Viewing the Rohlin invariant as a family of classes \(R_g \in H^1(\mathcal{T}_{g,1}; \mathbb{Z}/2\mathbb{Z})\), we have

\[\beta_\mathbb{Z}(R_g) = [J_g],\]

where \(\beta_\mathbb{Z}\) stands for the integral Bockstein operation.

We wish to point out that this construction of an invariant as a compatible family of trivializations of the pull-backs of cocycles \(2J_g\) is independent of the construction of the Casson invariant.
Indeed we prove directly from the algebraic relations
\[ F_g(\phi) + F_g(\psi) - F_g(\phi\psi) = 2J_g(\tau(\phi), \tau(\psi)) \]

satisfied by the maps \( F_g \) that our invariant \( F \) satisfies also the following surgery formulas properties (see Propositions 13 and 14 in Section 3):

**Proposition 1.** Let \( K \subset M \) be a knot in the oriented homology sphere \( M \). For an integer \( n \geq 1 \) denote by \( K_n \) the result of performing a \( \frac{1}{n} \)-Dehn surgery on \( K \).

1. The difference \( F'(K) = F(K_{n+1}) - F(K_n) \) is independent of \( n \).
2. If the knots \( K \) and \( L \) bound disjoint Seifert surfaces in \( M \) then the alternating sum

\[ F''(K, L) = F(K_{k+1}, L_{l+1}) - F(K_k, L_{l+1}) - F(K_{k+1}, L_l) + F(K_k, L_l) \]

is independent of the integers \( k \) and \( l \) and in fact is 0.

As was proved by Casson an invariant of homology spheres that satisfies the above two properties and which vanishes on \( S^3 \) is proportional to “the” Casson invariant.

Here is the plan of this paper. In Section 1 we turn back to the definition of the groups \( A_{g,1}, B_{g,1}, AB_{g,1} \), we describe their actions on the first homology and homotopy groups of the underlying surface and we prove Theorem 1. In Section 2 we study the relationship between trivial cocycles on the Torelli group and invariants of homology spheres. In particular we prove Theorem 2 up to a technical Lemma which is delayed until Section 4. In Section 3 we apply our results to give a purely algebraic construction of the Casson invariant and we prove Theorems 3 and 4 and Proposition 1. Finally, in Section 4 we cope with the proof of the technical Lemma.

**General conventions.** The properties of the genus 1 and 2 mapping class groups and their subgroups is very peculiar. Since the injectivity of the stabilization map \( \mathcal{M}_{g,1} \hookrightarrow \mathcal{M}_{g+1,1} \) implies that in our case it is enough to consider large enough values of \( g \) we will always assume that \( g \geq 3 \). All invariants considered will take the value 0 on the standard oriented sphere \( S^3 \). If \( \gamma \) denotes a simple closed curve on the surface \( \Sigma_g \), we will denote by \( T_\gamma \) the right-hand Dehn twist about \( \gamma \).

## 1. Heegaard splittings of homology spheres

1.1. **The mapping class group and some of its subgroups.** For convenience we fix a model of our genus \( g \) surface \( \Sigma_g \) as in Figure 1. We denote by \( \Sigma_{g,1} \) the complement of the interior of a small disc embedded in \( \Sigma_g \). We fix a base point on the boundary of \( \Sigma_{g,1} \). The (isotopy class of) the curves \( \alpha_i, \beta_i \; 1 \leq i \leq g \) are free generators of the free group \( \pi_1(\Sigma_{g,1}, x_0) \). The first homology group of the surface \( H_1(\Sigma_g; \mathbb{Z}) = H \) is endowed via Poincaré duality with a natural symplectic intersection form \( \omega : \wedge^2 H \to \mathbb{Z} \). The homology classes \( a_i, b_i \) of the above curves freely generate the abelian group \( H \simeq \mathbb{Z}^{2g} \) and define two transverse Lagrangians \( A \) and \( B \) in \( H \).

Denote by \( \text{Diff}^+(\Sigma_g, \text{rel.}, D^2) \) the group of orientation preserving diffeomorphisms of \( \Sigma_g \) that are the identity on the fixed small disc, endowed with the compact-open topology. The mapping class group \( \mathcal{M}_{g,1} \) is the group of connected components \( \mathcal{M}_{g,1} = \pi_0(\text{Diff}^+(\Sigma_g, \text{rel.}, D^2)) \).
TRIVIAL COCYCLES AND INVARIANTS OF HOMOLOGY 3-SPHERES

The natural action of the mapping class group $\mathcal{M}_{g,1}$ on $H$ clearly preserves the intersection form and we have a short exact sequence where the kernel is known as the Torelli group $\mathcal{T}_{g,1}$:

$$1 \rightarrow \mathcal{T}_{g,1} \rightarrow \mathcal{M}_{g,1} \rightarrow \text{Sp}\omega \rightarrow 1.$$ 

Recall that our surface is standardly embedded in the oriented 3-sphere $S^3$. As such it determines two embedded handlebodies $S^3 = \mathcal{H}_g \cup -\mathcal{H}_g$. By the inner handlebody $\mathcal{H}_g$ we will mean the one that is visible in Figure 1 and by the outer handlebody $-\mathcal{H}_g$ we will mean the complementary handlebody. They are naturally pointed by $x_0 \in \mathcal{H}_g \cap -\mathcal{H}_g$.

From these we get three natural subgroups of $\mathcal{M}_{g,1}$. First, the subgroup of those mapping classes that are restrictions of diffeomorphisms of the inner handlebody $\mathcal{H}_g$ which we call $\mathcal{B}_{g,1} \subset \mathcal{M}_{g,1}$. Second, the subgroup of those that are restrictions of the outer handlebody $\mathcal{A}_{g,1} \subset \mathcal{M}_{g,1}$. Finally, their intersection $\mathcal{AB}_{g,1}$, which may be identified to subgroup of mapping classes that are restrictions of diffeomorphisms of the whole sphere that leave our embedded surface invariant. We denote the groups $\mathcal{T}_{g,1} \cap \mathcal{A}_{g,1}$, $\mathcal{T}_{g,1} \cap \mathcal{B}_{g,1}$ and $\mathcal{T}_{g,1} \cap \mathcal{AB}_{g,1}$ respectively by $\mathcal{T}\mathcal{A}_{g,1}$, $\mathcal{T}\mathcal{B}_{g,1}$ and $\mathcal{T}\mathcal{AB}_{g,1}$.

**Remark:** In this article we deal mostly with mapping class groups relative to a boundary component. Most references, in particular those dealing with the subgroups $\mathcal{A}_{g,1}, \mathcal{B}_{g,1}, \mathcal{AB}_{g,1}$ [3], [12], [21] are written for closed surfaces but lifting their results to the boundary case is not difficult. Indeed, taking isotopy class of diffeomorphisms of the closed surface relative to the base point $x_0$ gives us another mapping class group usually denoted by $\mathcal{M}_{g,*}$. The natural “forgetfull” operation induces a surjective map $\mathcal{M}_{g,1} \rightarrow \mathcal{M}_{g,*}$. Its kernel is generated by a Dehn twist around a curve parallel to the boundary and we get a short exact sequence:

$$1 \rightarrow \mathbb{Z} \rightarrow \mathcal{M}_{g,1} \rightarrow \mathcal{M}_{g,*} \rightarrow 1.$$ 

The mapping class group of the “inner” handlebody $\mathcal{H}_g$ relative to the base point can be identified with a subgroup $\mathcal{B}_{g,*} \subset \mathcal{M}_{g,*}$, where the inclusion is induced by restricting mapping classes to the boundary. Since the aforementioned Dehn twist extends naturally to the handlebody $\mathcal{H}_g$ the preimage of $\mathcal{B}_{g,1} \subset \mathcal{M}_{g,1}$ of $\mathcal{B}_{g,*}$ can be identified as the mapping class group of the handlebody $\mathcal{H}_g$ relative to a small ball $B^3$ such that $B^3 \cap \Sigma_g$ is our distinguished small disk $D^2$ and we get a commutative
diagram with vertical arrows induced by restricting to the boundary.

$$\begin{array}{cccccc}
1 & \rightarrow & \mathbb{Z} & \rightarrow & M_{g,1} & \rightarrow & M_{g,1}^* & \rightarrow & 1 \\
1 & \rightarrow & \mathbb{Z} & \rightarrow & \mathcal{B}_{g,1} & \rightarrow & \mathcal{B}_{g,1}^* & \rightarrow & 1.
\end{array}$$

Similar identifications hold for the groups $A_{g,1}$ and $AB_{g,1}$.

1.2. Homology and homotopy actions. According to Griffith [4], the subgroup $B_{g,1}$ (resp. $A_{g,1}$) is characterized by the fact that its action on $\pi_1(\Sigma_g, x_0)$ preserves the normal subgroup generated by the curves $\beta_1, \ldots, \beta_g$ (resp. $\alpha_1, \ldots, \alpha_g$). As a consequence the action on homology of $B_{g,1}$ (resp. $A_{g,1}$) preserves the Lagrangian $B_g$ (resp. $A_g$).

If one writes the matrices of the symplectic group $Sp_\omega$ as blocks according to the decomposition $H = A \oplus B$, then the image of $B_{g,1} \rightarrow Sp_\omega$ is contained in the subgroup $Sp_{B_g}$ of matrices of the form:

$$\begin{pmatrix} G_1 & 0 \\ M & G_2 \end{pmatrix}.$$

Such matrices are symplectic if and only if $G_2 = t^{-1}G_1^t$ and $tG_1M$ is symmetric and we have an isomorphism:

$$Sp_{B_g} \xrightarrow{\sim} GL_g(\mathbb{Z}) \ltimes S_g(\mathbb{Z}),$$

with composition on the semi-direct product given by the rule $(G, S)(H, T) = (GH, t^GHS + T)$. Checking on generators (see Suzuki [21]) of $B_{g,1}$ we get:

**Lemma 1.** There is a short exact sequence of groups:

$$1 \rightarrow T B_{g,1} \rightarrow B_{g,1} \rightarrow GL_g(\mathbb{Z}) \ltimes S_g(\mathbb{Z}) \rightarrow 1.$$

An analogous statement holds for $A_{g,1}$ replacing the lagrangian $B$ by $A$.

We also recall a result due to Luft [12, Corollary 2.1]

**Lemma 2.** The natural homomorphism $B_{g,1} \rightarrow Aut \pi_1(\mathcal{H}_g, x_0)$ is onto.

Again an analogous statement holds for $A_{g,1}$. If we restrict our attention to $AB_{g,1}$ then the natural homomorphism $AB_{g,1} \rightarrow Aut \pi_1(\mathcal{H}_g, x_0)$ is still an automorphism for the elements of $B_{g,1}$ that hit the generators of the automorphism group in Luft’s paper are readily seen to live in fact in $AB_{g,1}$ (for a geometric description of these generators see [12] or [21] and for an algebraic description see Section 4). As for the previous Lemma, checking on generators we get:

**Lemma 3.** There is a short exact sequence of groups:

$$1 \rightarrow T AB_{g,1} \rightarrow AB_{g,1} \rightarrow GL_g(\mathbb{Z}) \rightarrow 1.$$

1.3. Heegaard splittings of homology spheres. It is well known that by gluing two handlebodies with opposite orientations along a diffeomorphism of their boundary one can construct all oriented compact 3 manifolds. Choose a map $\iota_g \in \mathcal{M}_{g,1}$ such that $S^3 = \mathcal{H}_g \cup_{\iota_g} -\mathcal{H}_g$. If we twist this gluing by an arbitrary map in $T_{g,1}$ we get back a new homology sphere $S^3_\phi = \mathcal{H}_g \cup_{\iota_g \phi} -\mathcal{H}_g$ and in fact we
can get all homology spheres by letting \( g \) vary \([15]\). More precisely, consider the following equivalence relation on \( T_{g,1} \):

\[
\phi \sim \psi \iff \exists \zeta_a \in A_{g,1} \exists \zeta_b \in B_{g,1} \text{ such that } \zeta_b \phi \zeta_a = \psi. \quad (*)
\]

Moreover define the \textit{stabilization map} on the mapping class group as follows. Glue one of the boundary components of a two holed torus on the boundary of \( \Sigma_{g,1} \) to get \( \Sigma_{g+1,1} \). Extending an element of \( \mathcal{M}_{g,1} \) by the identity over the torus yields an injective homomorphism \( \mathcal{M}_{g,1} \to \mathcal{M}_{g+1,1} \), this is the stabilization map. This map is compatible with the action on homology and is compatible with the definition of the above two subgroups \( A_{g,1} \) and \( B_{g,1} \). In particular the equivalence relation \((*)\) is compatible with the stabilisation map. It is also possible to choose the map \( i_g \) to be compatible with the stabilization map \( i_{g+1} \mid_{\Sigma_{g,1}} = i_g \) and we have the following precise version of Heegaard splittings of integral homology spheres (see \([15]\) for a proof):

**Theorem 5.** The following map is well defined and is bijective:

\[
\lim_{g \to \infty} T_{g,1} / \sim \longrightarrow S(3) \quad \phi \quad \longmapsto S_\phi^3 = H_g \cup_{\phi} -H_g
\]

From a group-theoretical point of view the equivalence relation \((*)\) is quite unsatisfactory, for it looks like, but is not, a double coset relation on the Torelli group. In fact it is the composite of a double coset relation in the Torelli group and a conjugacy-induced equivalence relation:

**Theorem 6.** Two maps \( \phi, \psi \in T_{g,1} \) are equivalent if and only if there exists a map \( \mu \in AB_{g,1} \) and two maps \( \xi_a \in TA_{g,1} \) and \( \xi_b \in TB_{g,1} \) such that \( \phi = \mu \xi_b \psi \xi_a \mu^{-1} \).

**Proof.** The “if” part of the theorem is trivial. Conversely, assume that \( \psi = \xi_b \phi \xi_a \), where \( \psi, \phi \in T_{g,1} \). Projecting this equality on \( \text{Sp} \omega \) we get \( Id = H_1(\xi_a)H_1(\xi_b) \).

According to Lemma 4 the matrix \( H_1(\xi_a) \) is of the form

\[
\begin{pmatrix}
G & 0 \\
M & tG^{-1}
\end{pmatrix}.
\]

Similarly, \( H_1(\xi_a) \) is of the form

\[
\begin{pmatrix}
H & N \\
0 & tH^{-1}
\end{pmatrix}.
\]

Therefore :

\[
Id = \begin{pmatrix}
H & N \\
0 & tH^{-1}
\end{pmatrix} \begin{pmatrix}
G & 0 \\
M & tG^{-1}
\end{pmatrix} = \begin{pmatrix}
HG + NM & NtG^{-1} \\
tH^{-1}M & tH^{-1}G^{-1}
\end{pmatrix}.
\]

Thus :

\[
N = 0 = M \text{ and } G = H^{-1}.
\]

In particular \( H_1(\xi_a) \), \( H_1(\xi_b) \) \( \in \text{GL}(g, \mathbb{Z}) \) and \( H_1(\xi_a) = H_1(\xi_b)^{-1} \). By Lemma 9 we can choose a map \( \mu \in AB_{g,1} \) such that \( H_1(\mu) = H_1(\xi_b) \), and we get

\[
\psi = \mu \circ (\mu^{-1} \xi_b) \phi (\xi_a \mu) \circ \mu^{-1}.
\]

By construction \( (\mu^{-1} \xi_b) \in TB_{g,1} \) and \( (\xi_a \mu) \in TA_{g,1} \). \( \square \)
2. Trivial cocycles and invariants

2.1. The Johnson homomorphism. Computing the action of the Torelli group on the second nilpotent quotient of \( \pi_1(\Sigma_{g,1}, x_0) \) Johnson defines a morphism of groups known as the first Johnson homomorphism:

\[
\tau : T_{g,1} \longrightarrow \wedge^3 H.
\]

Notice that the mapping class group \( \mathcal{M}_{g,1} \) acts naturally by conjugation on \( T_{g,1} \) and acts also on \( \wedge^3 H \) via its natural action on homology. In [9], [10], [11] Johnson proves that

**Proposition 2.** The map \( \tau \) is \( \mathcal{M}_{g,1} \)-equivariant with respect to the above actions. Up to finite dimensional \( \mathbb{Z}/2\mathbb{Z} \)-vector space \( \wedge^3 H \) is the abelianization of the Torelli group: any homomorphism \( T_{g,1} \to A \) where \( A \) is an abelian group without 2-torsion factors uniquely through \( \tau \).

2.2. From invariants to trivial cocycles. Consider an integer valued invariant of homology spheres \( F : S(3) \to \mathbb{Z} \). Precomposing with the canonical maps \( T_{g,1} \to \lim_{g \to \infty} T_{g,1} \to S(3) \) we get a family of maps \( F_g : T_{g,1} \to \mathbb{Z} \). Since the stabilization maps are injective the map \( F_g \) determines by restriction all maps \( F_{g'} \) for \( g' < g \). Therefore, as stated in the introduction, we avoid the peculiarities of the first Torelli groups by restricting ourselves to \( g \geq 3 \). We also consider the associated trivial cocycles, which measure the failure of the maps \( F_g \) to be homomorphisms of groups

\[
C_g : T_{g,1} \times T_{g,1} \longrightarrow \mathbb{Z} \\
(\phi, \psi) \longmapsto F_g(\phi) + F_g(\psi) - F_g(\phi \psi).
\]

Since \( F \) is an invariant the cocycles \( C_g \) inherit the following properties:

1. The cocycles \( C_g \) are compatible, i.e. the following diagram of maps commutes:

\[
\begin{array}{ccc}
T_{g,1} \times T_{g,1} & \longrightarrow & \mathbb{Z} \\
\downarrow & & \downarrow \\
T_{g+1,1} \times T_{g+1,1} & \longrightarrow & C_{g+1}
\end{array}
\]

2. The cocycles \( C_g \) are invariant under conjugation by elements in \( AB_{g,1} : C_g(\phi - \phi^{-1}, \phi - \phi^{-1}) = C_g(-, -) \).
3. If \( \phi \in TB_{g,1} \) or \( \psi \in TA_{g,1} \) then \( C_g(\phi, \psi) = 0 \).

**Proposition 3.** The cocycle \( C_g \) is constantly equal to 0 if and only if \( F_g \) is the zero map.

**Proof.** If \( C_g = 0 \) then \( F_g \) is a morphism of groups and therefore factors via \( \tau \):

\[
\begin{array}{ccc}
T_{g,1} & \longrightarrow & \wedge^3 H \\
\downarrow & & \downarrow \\
\mathbb{Z} & \longrightarrow & \mathbb{Z}
\end{array}
\]

The morphism \( \overline{F}_g \) is then \( GL_g(\mathbb{Z}) = AB_{g,1}/TA_{g,1} \)-invariant. As \( -\text{Id} \in GL_g(\mathbb{Z}) \) acts as \( -\text{Id} \) on \( \wedge^3 H \), we get that \( \overline{F}_g = 0 \).

Any two trivializations of a given trivial cocycle differ by a homomorphism of groups and by the same argument we get:
**Proposition 4.** Any family of trivial cocycles satisfying (1) – (3) corresponds to at most one invariant of homology spheres.

2.3. From trivial cocycles to invariants. Conversely, what are the conditions for a family of trivial 2-cocycles $C_q$ on $T_{g,1}$ satisfying properties (1) – (3) to actually provide an invariant?

Firstly we need to check the existence of an $AB_{g,1}$-invariant trivialization of each $C_q$. This is a cohomological problem.

Denote by $Q_{C_q}$ the set of all trivializations of the cocycle $C_q$:

$$Q_{C_q} = \{ q : T_{g,1} \to \mathbb{Z} \, | q(\phi) + q(\psi) - q(\phi \psi) = C_q(\phi, \psi) \}.$$  

Recall that any two trivializations differ by an element of the group $\text{Hom}(T_{g,1}, \mathbb{Z}) = \text{Hom}(\wedge^3 H, \mathbb{Z})$. As the cocycle $C_q$ is invariant under conjugation by $AB_{g,1}$ this later group acts on $Q_{C_q}$ via its conjugation action on the Torelli group. Explicitly if $\phi \in AB_{g,1}$ and $q \in Q_{C_q}$ then $\phi \cdot q(q) = q(\phi \eta \phi^{-1})$. This action confers the set $Q_{C_q}$ the structure of an affine set over the abelian group $\text{Hom}(\wedge^3 H, \mathbb{Z})$. Choose an arbitrary element $q \in Q_{C_q}$ and define a map as follows

$$\rho_q : AB_{g,1} \to \text{Hom}(\wedge^3 H, \mathbb{Z})$$

$$\phi \mapsto \phi \cdot q - q.$$  

A direct computation shows that $\rho_q$ is a derivation and that the difference $\rho_q - \rho_{q'}$ for two elements in $Q_{C_q}$ is a principal derivation, therefore we have a well-defined cohomology class

$$\rho(C_q) \in H^1(AB_{g,1}; \text{Hom}(\wedge^3 H, \mathbb{Z}))$$

called the torsor of the cocycle $C_q$.

By construction if the action of $AB_{g,1}$ on $Q_{C_q}$ has a fixed point the class $\rho(C_q)$ is trivial. Conversely, if $\rho(C_q)$ is trivial, then for any $q \in Q_{C_q}$ the map $\rho_q$ is a principal derivation: there exists $m \in \text{Hom}(T_{g,1}, \mathbb{Z})$ such that

$$\forall \phi \in AB_{g,1} \quad \rho_q(\phi) = \phi \cdot m - m.$$  

In particular the element $q - m \in Q_{C_q}$ is fixed under the action of $AB_{g,1}$.

**Proposition 5.** The natural action of $AB_{g,1}$ on $Q_{g,1}$ admits a fixed point if and only if the associated torsor $\rho(C_q)$ is trivial.

Arguing as in Proposition 5 one checks that the $AB_{g,1}$-invariant trivialization of $C_q$, if it exists, is unique. If we have fixed points $q_g$ for all $g$, by unicity, we have that $q_{g+1}$ restricted to $T_{g,1}$ is equal to $q_g$. Therefore we have a well-defined map

$$q = \lim_{g \to \infty} q_g : \lim_{g \to \infty} T_{g,1} \to \mathbb{Z}.$$  

This is the only candidate to be an invariant of homology spheres. For this map to be an invariant, since it is already $AB_{g,1}$-invariant, we only have to prove that it is constant on the double cosets $TB_{g,1}\backslash T_{g,1}/TA_{g,1}$.

From property (3) of our cocycle we get that $\forall \phi \in T_{g,1}, \forall \psi_a \in TA_{g,1}$ and $\forall \psi_b \in TB_{g,1}$:

$$q_g(\phi) - q_g(\psi_b \phi) = -q_g(\psi_b)$$

$$q_g(\phi) - q_g(\psi_a) = -q_g(\psi_a)$$
**Theorem 7.** For each \( g \geq 3 \) the induced homomorphisms
\[
q_g : \mathcal{T}B_{g,1} \to \mathbb{Z} \quad \text{and} \quad q_g : \mathcal{T}A_{g,1} \to \mathbb{Z}
\]
are trivial.

**Proof.** We only give the proof for the morphism \( q_g : \mathcal{T}B_{g,1} \to \mathbb{Z} \), the other case is similar.

Denote by \( L_{g,1} \) the kernel of the map \( B_{g,1} \to \text{Aut} \pi_1(\mathcal{H}_g) \). This was identified by Luft \[12\] as the “Twist group” of the handlebody \( \mathcal{H}_g \).

Consider the following commutative diagram
\[
\begin{array}{cccccc}
1 & \to & L \cap \mathcal{T}B_{g,1} & \to & \mathcal{T}B_{g,1} & \to & IA & \to & 1 \\
& & \downarrow & & \downarrow & & \downarrow & & \\
1 & \to & L_{g,1} & \to & B_{g,1} & \to & \text{Aut} \pi_1(\mathcal{H}_g) & \to & 1
\end{array}
\]

Here \( IA \) stands for the kernel of the natural map \( \text{Aut}(\mathcal{H}_g) \to \text{GL}_g(\mathbb{Z}) \). In Section 4 we prove the following result:

**Proposition 6.** The group \( L \cap \mathcal{T}B_{g,1} \) is generated by maps of the form \( T_\beta T_\beta^{-1} \), where \( \beta \) and \( \beta' \) are two homologous non-isotopic and disjoint simple closed curves on \( \Sigma_{g,1} \) such that each one bounds a properly embedded disc in \( \mathcal{H}_g \).

**Corollary 1.** The morphism \( q_g : L \cap \mathcal{T}B_{g,1} \to \mathbb{Z} \) is trivial.

**Proof.** By Proposition 6 it is enough to prove that \( q_g \) vanishes on the aforementioned maps \( T_\beta T_\beta^{-1} \). As our embedding of \( \Sigma_g \) into \( S^3 \) is standard, there exists a simple closed curve, \( \alpha \subset \Sigma_{g,1} \) which bounds a properly embedded disc on \( -\mathcal{H}_g \) (the outer handlebody) and which intersects each of the curves \( \beta \) and \( \beta' \) in exactly one point. Consider a regular neighbourhood of the union \( \beta \cup \alpha \cup \beta' \), it is a 3-ball, whose intersection with the surface looks like in Figure 2.

There is a half twist map \( \psi \) inside this ball that exchanges the curves \( \beta \) and \( \beta' \). This half twist map \( \psi \) belongs to \( \mathcal{A}B_{g,1} \) since it is a self diffeomorphism of the depicted 3-ball and can be extended by the identity outside this ball. In particular,
since \( q \) is \( AB_{g,1} \)-invariant:

\[
q_g(T_\beta T_{\beta'}^{-1}) = q_g(T_\psi(\beta) T_{\psi(\beta')}^{-1}) = q_g(T_\beta T_{\beta'}^{-1}) = -q_g(T_\beta T_{\beta'}^{-1})
\]

and therefore \( q_g|_{\mathcal{L} \cap \mathcal{TB}_{g,1}} = 0. \) \( \square \)

As a consequence \( q_g \) factors through \( IA \). As the action on the fundamental group of the inner handlebody \( \mathcal{H}_g \) induces a surjective map \( AB_{g,1} \to Aut \pi_1(\mathcal{H}_g) \) we can even view \( q_g \) as an \( Aut \pi_1(\mathcal{H}_g) \)-invariant map \( q_g : IA \to Z \). Let \( \alpha_1, \ldots, \alpha_g \) denote the generators of \( \pi_1(\mathcal{H}_g) \) (this can be identified with the curves in Figure 1). According to Magnus [13], the group \( IA \) is normally generated as a subgroup of \( Aut \pi_1(\mathcal{H}_g) \) by the automorphism \( K_{12} \) given by \( K_{12}(\alpha_1) = \alpha_2 \alpha_1 \alpha_2^{-1} \) and \( K_{12}(\alpha_i) = \alpha_i \) for \( i \geq 2 \). By invariance, \( q_g \) is determined by its value on \( K_{12} \).

An easy computation shows that if we denote by \( \sigma_2 \) the automorphism given by \( \sigma_2(\alpha_2) = \alpha_2^{-1} \) and \( \sigma_2(\alpha_i) = \alpha_i \) for \( i \neq 2 \) then \( \sigma_2 K_{12} \sigma_2^{-1} = K_{12}^{-1} \). In particular \( q_g(K_{12}) = q_g(\sigma_2 K_{12} \sigma_2^{-1}) = -q_g(K_{12}) \) and \( q_g \) must be trivial. \( \square \)

We summarize the discussion of this section in the following

**Theorem 8.** A family of cocycles \( (C_g)_{g \geq 3} \) on the Torelli groups \( \mathcal{T}_{g,1} \), \( g \geq 3 \) satisfying conditions (1)–(3) provides a compatible family of trivializations \( F_g : \mathcal{T}_{g,1} \to Z \) that reassemble into an invariant of homology spheres

\[
\lim_{g \to \infty} F_g : S(3) \to Z
\]

if and only if the following two conditions hold:

1. The associated cohomology classes \( [C_g] \in H^2(\mathcal{T}_{g,1}; Z) \) are trivial.
2. The associated torsors \( \rho(C_g) \in H^1(AB_{g,1}, \wedge^3 H_1(\Sigma_g)) \) are trivial.

In this case the maps \( F_g \) are the unique \( AB_{g,1} \)-invariant trivializations of the cocycles \( C_g \).

### 3. Application to the Casson Invariant

If one is interested in invariants that come from pull-backing cocycles defined on abelian groups without 2-torsion, in view of Proposition 2 it is enough to study the case where the abelian group is \( \wedge^3 H \) and the homomorphism is \( \tau \).

Recall that we have a decomposition \( H = A \oplus B \), this induces the decomposition \( \wedge^3 H = \wedge^3 A \oplus B \wedge \wedge^2 A + A \wedge \wedge^2 B \). Set \( W_A = \wedge^3 A \), \( W_B = \wedge^3 B \) and \( W_{AB} = \oplus B \wedge \wedge^2 A + A \wedge \wedge^2 B \). The Johnson homomorphism computes the action of the Torelli group on the second nilpotent quotient of the fundamental group of \( \Sigma_{g,1} \). Computing on specific elements one can check that (see [13]):

**Lemma 4.** The image of \( \mathcal{TB}_{g,1} \) under \( \tau \) in \( \wedge^3 H \) is \( W_A \oplus W_{AB} \), the image of \( \mathcal{T} A_{g,1} \) is \( W_{AB} \oplus W_B \).

For each \( g \), the symplectic pairing \( \omega : \wedge^2 H \to Z \) induces natural pairings \( J_g : W_A \wedge W_B \to Z \) and \( J_g : W_B \wedge W_A \to Z \) that can be naturally extended to
degenerate bilinear forms on $\Lambda^3H = W_A \oplus W_{AB} \oplus W_B$, with matrices:

$$J_g := \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ Id & 0 & 0 \end{pmatrix}, \quad t J_g := \begin{pmatrix} 0 & 0 & Id \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$ 

Notice that bilinear forms are naturally 2-cocycles on abelian groups.

**Proposition 7.** For each $g \geq 3$, the cocycle $J_g$ is the unique cocycle (up to a multiplicative constant) on $\Lambda^3H$ which pull-back on the Torelli group $T_{g,1}$ satisfies conditions (2) and (3). Moreover once we have fixed a common multiplicative constant the family of pull-backed cocycles satisfies also (1).

**Proof.** Fix an integer $n \in \mathbb{Z}$. It is obvious from the definition and from Lemma 3 that the family $(nJ_g)$ satisfies (1), (2) and (3).

Let $B$ denote an arbitrary cocycle on $\Lambda^3H$ which pull-back on $T_{g,1}$ satisfies (2) and (3).

Write each element $w \in \Lambda^3H$ as $w_a + w_{ab} + w_b$ according to the decomposition $W_A \oplus W_{AB} \oplus W_B$. The cocycle relation together with condition (3) and Lemma 3 imply that

$$\forall v, w \in \Lambda^3H \quad B(v, w) = B(v_a, w_b).$$

We first prove that $B$ is bilinear. For the linearity on the first variable compute

$$B(u + v, w) = B(u_a + v_a, w_b) = B(u_a, w_b) + B(u_a, v_a + w_b) - B(u_a, v_a) = B(u_a, w_b) + B(v_a, w_b) = B(u, w) + B(v, w).$$

A similar proof holds for the linearity on the second variable.

By the equivariance properties of $\tau$, the subgroup $\mathcal{A}B_{g,1} \subset \mathcal{M}_{g,1}$ acts on $\Lambda^3H$ via the projection $\mathcal{A}B_{g,1} \xrightarrow{H} \text{GL}_g(\mathbb{Z})$. It is well known that the only $\text{GL}_g(\mathbb{Z})$-invariant bilinear forms on $\Lambda^3(A \oplus B)$ are the pairing $J_g$ and the dual pairing $t J_g$, so that $B = nJ + m^*J$ for some integers $n$ and $m$. As condition (3) implies that $\tau(T_{g,1}) = W_B \oplus W_{AB}$ has to be in the kernel of $B$, evaluating on the elements of $W_B$ yields that $m = 0$.

We would like to apply Theorem 8 to the family $(J_g)$ or to one of its multiples. First we must check the triviality of the cocycles.

**Proposition 8.** For all $g \geq 3$, the pull-back of the 2-cocycle $2J_g$ is trivial.

**Proof.** From Johnson (see Proposition 2) we know that the abelianization of $T_{g,1}$ is equal to $\Lambda^3H \oplus V$ where $V$ is a $\mathbb{Z}/2\mathbb{Z}$-vector space. By the universal coefficients theorem $H^2(T_{g,1}, \mathbb{Z}) = \text{Hom}(H_2(T_{g,1}, \mathbb{Z}), \mathbb{Z}) \oplus \text{Ext}^1(H_1(T_{g,1}, \mathbb{Z}), \mathbb{Z})$. The first factor is torsion free and the second factor is isomorphic to $\text{Ext}^1(V, \mathbb{Z})$ which is a $\mathbb{Z}/2\mathbb{Z}$ vector space.

By naturality we have a commutative diagram for cohomology groups with trivial coefficients:

$$
\begin{array}{ccc}
H^2(\Lambda^3H ; \mathbb{Q}) & \xrightarrow{\tau^*} & H^2(T_{g,1} ; \mathbb{Q}) \\
\downarrow & & \downarrow \\
H^2(\Lambda^3H ; \mathbb{Z}) & \xrightarrow{\tau^*} & H^2(T_{g,1} ; \mathbb{Z})
\end{array}
$$
R. Hain [3] has computed the kernel of $\tau^0_\varphi$ and a direct computation shows that the image of the pull-back of $J_g$ in $H^2(\wedge^3 H; \mathbb{Q})$ lies in this kernel. In particular $\tau^*(J_g)$ is annihilated by multiplication by 2 so that the pull-back of the 2-cocycle $2J_g$ is trivial. \hfill \square

We will come back to the homology class of the pull-back of the cocycle $J_g$ later (see Proposition 10). To avoid an unnecessarily heavy notation from now on we will also denote by $J_g$ the pull-back of the cocycle $J_g$ along the morphism $\tau$. To see if there is an invariant associated to the family $(2J_g)_{g \geq 3}$ we have to check the triviality of the associated torsors:

**Proposition 9.** For each $g \geq 3$, the torsor

$$\rho(2J_g) \in H^1(\mathbb{T}A\mathbb{B}_{g,1}; \text{Hom}(\Lambda^3 H, \mathbb{Z}))$$

is trivial.

**Proof.** By definition we have an exact sequence

$$\begin{array}{cccccc}
1 & \longrightarrow & T A\mathbb{B}_{g,1} & \longrightarrow & A\mathbb{B}_{g,1} & \longrightarrow & GL_g(\mathbb{Z}) & \longrightarrow & 1
\end{array}$$

We get an induced exact sequence in low-dimensional cohomology:

$$\begin{array}{cccccc}
0 & \longrightarrow & H^1(GL_g(\mathbb{Z}); \text{Hom}(\Lambda^3 H, \mathbb{Z})) & \longrightarrow & H^1(A\mathbb{B}_{g,1}; \text{Hom}(\Lambda^3 H, \mathbb{Z})) & \longrightarrow & H^1(T A\mathbb{B}_{g,1}; \text{Hom}(\Lambda^3 H, \mathbb{Z}))^{GL_g(\mathbb{Z})}.
\end{array}$$

First we show that $H^1(GL_g(\mathbb{Z}); \text{Hom}(\Lambda^3 H, \mathbb{Z})) = 0$. Let $f : GL_g(\mathbb{Z}) \rightarrow \Lambda^3 H$ be any crossed morphism. As $-Id \in GL_g(\mathbb{Z})$ acts as $-Id$ on $\text{Hom}(\Lambda^3 H, \mathbb{Z})$ and is central, for all $S \in GL_g(\mathbb{Z})$ we have $f(-Id \circ S) = f(-Id) - f(S) = f(S) + S \cdot f(-Id)$. In particular, $\forall S \in GL_g(\mathbb{Z})$, $2f(S) = f(-Id) - S \cdot f(-Id)$. Using the standard generators (elementary matrices) $E_{ij}(a_k) = a_k + \delta_{jk} a_i$, one shows that $f(-Id)$ is divisible by 2, so $f$ itself is a principal derivation.

We are left with the exact sequence:

$$0 \rightarrow H^1(A\mathbb{B}_{g,1}; \text{Hom}(\Lambda^3 H, \mathbb{Z})) \rightarrow H^1(T A\mathbb{B}_{g,1}; \text{Hom}(\Lambda^3 H, \mathbb{Z}))^{GL_g(\mathbb{Z})}.$$

As $T_{g,1}$ and therefore $T A\mathbb{B}_{g,1}$, acts trivially on the free abelian group $\text{Hom}(\Lambda^3 H, \mathbb{Z})$, the universal coefficients theorem and the classical adjunction properties of Hom-groups gives us a canonical $GL(g, \mathbb{Z})$-equivariant isomorphism

$$H^1(T A\mathbb{B}_{g,1}; \text{Hom}(\Lambda^3 H, \mathbb{Z})) \simeq \text{Hom}(H_1 T A\mathbb{B}_{g,1} \otimes \Lambda^3 H, \mathbb{Z}).$$

By construction of the torsor class, the image of $\rho(2J_g)$ under this isomorphism may be described as follows. Fix an arbitrary coboundary $q \in Q_2(\mathbb{Z})$. For each tensor $f \otimes l \in H_1(T A\mathbb{B}_{g,1}) \otimes \Lambda^3 H$, choose arbitrary lifts of $\phi \in T A\mathbb{B}(1)_{g,1}$ and $\lambda \in T_{g,1}$, then $\rho(2J_g)(f \otimes l) = q(\phi \lambda \phi^{-1}) - q(\lambda)$. As $q$ is a coboundary of $2J_g$ we get:

$$\rho(2J_g)(f \otimes l) = q(\phi \lambda \phi^{-1}) - q(\lambda)$$

$$= q(\phi \lambda \phi^{-1}) - q(\lambda)$$

$$= 2J_g(\tau(\phi), \tau(\lambda)) - 2J_g(\tau(\lambda), \tau(\phi))$$

$$= 0 \text{ by condition } (\ast).$$
Applying Theorem 8 we get

**Theorem 9.** The $\mathbb{AB}_{g,1}$-invariant trivializations of the pull-backs of the cocycles $2J_g$ reassemble into an invariant of homology spheres $F : S(3) \to \mathbb{Z}$. Up to a multiplicative constant this is trivialization of a 2-cocycle defined on an abelian group without 2-torsion.

In the next paragraph we identify the above invariant with the Casson invariant:

**Corollary 2.** The Casson invariant is the unique integral valued invariant of oriented homology 3-spheres that comes from the trivialization of a 2-cocycle defined on an abelian group without 2-torsion.

We also get back one of the main results in [15]:

**Corollary 3.** Denote by $K_{g,1}$ the kernel of the Johnson homomorphism $\tau$ (see [10] for geometric properties of this group). Then the Casson invariant restricted to $K_{g,1}$ is a homomorphism of groups.

Assuming that we know that our invariant $F$ constructed out of the cocycles $2J_g$ is the opposite of the Casson invariant we proceed by showing that one can not get rid of the factor 2. Denote the Casson invariant by $\lambda$ and by $\lambda_g$ if we view it as a function on $T_{g,1}$.

**Proposition 10.** The pullback of the cocycle $J_g$ on the Torelli group defines a non-trivial cohomology class $[J_g] \in H^2(T_{g,1}; \mathbb{Z})$ of order two. Moreover these classes are stable in the sense that the image of the class $[J_g+1]$ under the stabilisation map $H^2(T_{g+1,1}; \mathbb{Z}) \to H^2(T_{g,1}; \mathbb{Z})$ is $[J_g]$.

**Proof.** If the pullbacks were trivial then the proof of Proposition 9 would carry on and provide us with an invariant $F_g : T_{g,1} \to \mathbb{Z}$ associated to the family $(J_g)$. Then by the unicity of invariants associated to cocycles, Proposition 4, the invariant $2F_g$ would be the invariant associated to $2J_g$ so we would have $2F_g = -\lambda_g$. Now, the Poincaré sphere has a Heegaard splitting of genus 2 and therefore by stabilization, it has a Heegaard splitting of every genus $g \geq 3$. The Casson invariant of the Poincaré sphere is 1 and therefore all functions $\lambda_g$ take the value 1 and thus are not divisible by 2. \hfill \box

It is known that the mod 2 reduction of the Casson invariant is the Rohlin invariant, which might be viewed as an homomorphism $R_g : T_{g,1} \to \mathbb{Z}/2\mathbb{Z}$ or equivalently as a cohomology class $R_g \in H^1(T_{g,1}; \mathbb{Z}/2\mathbb{Z}) \simeq \text{Hom}(T_{g,1}, \mathbb{Z}/2\mathbb{Z})$. By definition of the Bockstein homomorphism $\beta_{\mathbb{Z}}$ associated to the exact sequence

$$1 \rightarrow \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \rightarrow \mathbb{Z}/2\mathbb{Z} \rightarrow 1,$$

we have :

**Proposition 11.** For $g \geq 3$, the image of the class $R_g$ under the integral Bockstein $\beta_{\mathbb{Z}} : H^1(T_{g,1}; \mathbb{Z}/2\mathbb{Z}) \rightarrow H^2(T_{g,1}; \mathbb{Z})$ is the non-trivial class $[J_g]$.

**Identification of the Casson invariant.** In this section we prove that the invariant $F$ derived from the family of cocycles $(2J_g)$ is the Casson invariant $\lambda$. For the classical construction of this invariant and the study of some of its properties we refer the reader to the survey book [1] or to the survey article [5].

Additivity of the Casson invariant under connected sum is a consequence of Propositions 13 and 14 hereafter (see [5]). We give here an independent proof as
Let \( F \) be an invariant of homology 3-spheres: if \( \phi \in T_{g,1} \) and \( \psi \in T_{h,1} \) then

\[
F(S^3_{\phi \psi}^3) = F(S^3_{\phi}^3) + F(S^3_{\psi}^3).
\]

**Proof.** It is a classical result in the theory of Heegaard splittings that a Heegaard splitting of genus \( g + h \) for the connected sum \( M \# N \) can be obtained from Heegaard splittings of genus \( g \) and \( h \) respectively of the manifolds \( M \) and \( N \) by splicing along 3-holed sphere, see Figure 3.

We see the surface \( \Sigma_{g,1} \subseteq \Sigma_{g+h,1} \) as containing the \( g \) first handles and the surface \( \Sigma_{h,1} \subseteq \Sigma_{g+h,1} \) as containing the last \( h \) handles. As for the stabilization map, extending by the identity we get two injective maps \( j_g : T_{g,1} \rightarrow T_{g+h,1} \) and \( j_h : T_{h,1} \rightarrow T_{g+h,1} \). If \( \phi \in T_{g,1} \) and \( \psi \in T_{h,1} \) then \( S^3_{\phi \psi} = S^3_{\phi} \cup S^3_{\psi} \). In particular

\[
F(S^3_{\phi \psi}^3) - F(S^3_{\phi}^3) - F(S^3_{\psi}^3) = -2J_{g+h}(\tau(j_g(\phi)), \tau(j_h(\psi))).
\]

If one turns back to the definition of the Johnson homomorphism \( J \) one can check that \( \tau(j_g(\phi)) \in \Lambda^3 \mathcal{H} \) only involves exterior powers of the homology classes \( a_i, b_i \) for \( i \leq g \) and \( \tau(j_h(\psi)) \in \Lambda^3 \mathcal{H} \) involves only exterior powers of the homology classes \( a_i, b_i \) for \( g < i \). Therefore \( J_{g+h}(\tau(j_g(\phi)), \tau(j_h(\psi))) = 0 \).

**Proposition 13.** Let \( M \) be an homology sphere and \( K \) a knot in \( M \). For an integer \( n \geq 1 \) denote by \( K_n \) the result of performing a \( \frac{1}{n} \) Dehn surgery on \( K \). Then \( F(K_{n+1}) - F(K_n) \) is independent of \( n \).

**Proof.** There exists a Heegaard splitting for \( M \) such that \( K \) belongs to the surface \( \Sigma_g \) and moreover is separating (i.e. \( \Sigma_g - K \) has two connected components) (see [11] Lemma 1.1 p.82) for instance). Doing a \( \frac{1}{n} \)-Dehn surgery on \( K \) is equivalent to modify the map \( \phi \in T_{g,1} \) such that \( S^3_{\phi} = M \) by the \( n \)th power of the Dehn twist along \( K \). Therefore

\[
F(K_{n+1}) - F(K_n) = F(S^3_{T_K^n}) - F(S^3_{T_K})
\]

\[
= F_g(T_K^n(\phi)) - F_g(T_K^0(\phi)) - F_g(T_K) = -2J_g(\tau(T_K^n(\phi)), \tau(T_K)).
\]

As \( K \) is separating \( \tau(T_K) = 0 \) (see [11]), therefore \( F(K_{n+1}) - F(K_n) = F(S^3_{T_K^n}) \) which is independent of \( n \).

Denote the quantity \( F(K_{n+1}) - F(K_n) \) by \( F'(K) \) or \( F'(K \subset M) \) if there is an ambiguity on the ambient space. If \( (K,L) \) is a link in the homology sphere \( M \), Proposition 12 shows that \( F(K_{k+1}, L_{l+1}) - F(K_k, L_l) + F(K_{k+1}, L_l) - F(K_{k+1}, L_{l+1}) \) is equal to \( F'(K \subset L_{l+1}) - F'(K \subset L_l) \) and to \( F'(L \subset K_{k+1}) - F'(L \subset K_k) \) and is therefore independent from \( k \) and \( l \). We denote this number by \( F''(K, L) \).
Proposition 14. Let $M$ be an homology sphere and let $K$ and $L$ be two knots in $M$ that bound disjoint Seifert surfaces in $M$. Then $F''(K, L) = 0$.

Proof. There is a Heegaard splitting of $M$, say of genus $g$, such that both $K$ and $L$ are separating curves on $\Sigma_g$ (see [1, Proposition 6.1, p.235]). Denote by $\phi$ a map in $T_{g,1}$ such that for the chosen Heegaard splitting $M = S^3_{\phi}$. Recall that $T_K$ and $T_L$ belong to the kernel of the map $\tau : T_{g,1} \rightarrow \wedge^3 H$ and that $F_g(\phi) + F_g(\psi) - F_g(\phi \psi) = 2J_g(\tau(\phi), \tau(\psi))$.

\[
F(K_{k+1}L_{l+1}) - F(K_kL_{l+1}) - F(K_{k+1}L_l) + F(K_kL_l)
= F_g(T_L^{l+1}T_K^{k+1} \phi) - F_g(T_L^{l+1}T_K^k \phi) - F_g(T_L^kT_K^{k+1}) + F_g(T_L^kT_K^k)
- F(\phi) + F_g(T_L^{l+1}T_K^k) + F(\phi)
= F_g(T_L^{l+1}T_K^{k+1} - F_g(T_L^{l+1}T_K^k) - F_g(T_L^kT_K^{k+1}) + F_g(T_L^kT_K^k)
= F_g(T_K) - F_g(T_L^{l+1}T_K^k) + F_g(T_L^kT_K^k)
= 2J_g(\tau(T_L^k), \tau(T_K^k))
= 0.
\]

Now from [5, Proposition 1.3, p.235] we learn that up to a multiplicative constant there exists a unique invariant of oriented homology sphere that is $0$ on $S^3$ and that satisfies Propositions 13 and 14 above. In particular as a consequence of the above two Propositions we get (see [5, Proposition 1.3, p.235])

1. (Surgery formula) Denote by $T$ the trefoil knot in $S^3$ and by $\Delta_K(t)$ the Alexander polynomial of a knot $K$ normalized at $1$.

Then $F'(K) = \frac{1}{3} \Delta''_K(1)F'(T)$.

2. (Change of orientation) If $-M$ denotes the oriented homology sphere $M$ with opposite orientation, then $F(-M) = -F(M)$.

Corollary 4. Up to a non-zero multiplicative constant, the invariant $F_g$ constructed in Theorem 4 is equal to the Casson invariant.

To fix the multiplicative constant we have to evaluate our invariant on one homology sphere and compute the value of the Casson invariant on the same sphere. Our invariant $F$ is most easily computed on maps of the form $\phi_a \phi_b$, with $\phi_a \in T\mathcal{A}_{g,1}$ and $\phi_b \in T\mathcal{B}_{g,1}$, for then:

\[
F(\phi_a \phi_b) = -2J(\tau(\phi_a), \tau(\phi_b)) + F(\phi_a) + F(\phi_b)
= -2J(\tau(\phi_a), \tau(\phi_b)).
\]

Consider the Dehn twists around the curves in Figures 4 and 5 where $+$ means a Dehn twist and $-$ means the inverse of a Dehn twist.

The homology of the curves in Figure 4 is $\pm a_2$, and the spine of the genus one sub-surface they bound has homology $a_1$ and $b_1 - a_3$. Therefore, according to Johnson [2] $\tau(\phi_a) = a_1 \wedge (b_1 - a_3) \wedge a_2$. Similarly, the curves in figure 5 have homology $\pm b_2$, the spin of the subsurface of genus one they bound has homology $a_1 + b_3, b_1$, so that $\tau(\phi_b) = (a_1 + b_3) \wedge b_1 \wedge b_2$.

From the definition of the cocycle $J_g$ we get that $F(S^3_{\phi_a \phi_b}) = -2J_g(a_1 \wedge (b_1 - a_3) \wedge a_2, (a_1 + b_3) \wedge b_1 \wedge b_2) = 2$. 

\[
\]
To compute the Casson invariant of $S^3_{\phi_a \phi_b}$ we proceed as follows. We have expressed the map $\phi_a \phi_b$ as a product of Dehn twists $T_{\gamma_4}T_{\gamma_3}^{-1}T_{\gamma_2}T_{\gamma_1}^{-1}$. Choose a small $\varepsilon > 0$ and push the first curve $\gamma_1$ by epsilon in the inner handlebody, similarly push the curve $\gamma_2$ by $2\varepsilon$ and so on. This yields a link in the inner handlebody with each component marked by $\pm 1$ according to the corresponding Dehn twist. Viewing this link in $S^3$ we get a surgery description of $S^3_{\phi_a \phi_b}$ (see for instance [20, p. 275]). A straightforward computation using the surgery formula shows that the Casson invariant of the homology sphere $S^3_{\phi_a \phi_b}$ is $-2$.

Proposition 15. Denote by $\lambda : S(3) \to \mathbb{Z}$ the Casson invariant. Then the functions $\lambda_g$ for $g \geq 3$ satisfy the equation:

$$\forall \phi, \psi \in \mathcal{T}_{g,1}, \quad \lambda(\phi \psi) - \lambda_g(\phi) - \lambda_g(\psi) = 2J_g(\tau(\phi), \tau(\psi)).$$

Corollary 5. The invariant $F$ constructed in Theorem 14 is the Casson invariant.

4. Generators for the Luft-Torelli group

In this section we finally prove Proposition 6. Before we need to recall some known facts on Dehn twists and maps in $\mathcal{T}B_{g,1}$.

In [12] Luft identified the kernel $L_{g,1}$ of the map

$$B_{g,1} \longrightarrow \text{Aut} \ \pi_1(H_g) \longrightarrow 1$$

with the so-called "Twist group": the subgroup of $\mathcal{M}_{g,1}$ generated by Dehn twists around simple closed curves that are contractible in $H_g$.

In analogy with the generators of the Torelli group defined by Johnson [11], we define a Contractible Bounding Pair (CBP for short) to be a pair of two disjoint and non-isotopic homologous curves $\beta$, $\beta'$ on $\Sigma_{g,1}$ such that neither $\beta$ nor $\beta'$ is null-homologous and such that each one bounds a properly embedded disk in $H_g$. A typical pair is given in Figure 2.
A Contractible Bounding Simple Closed Curve (CBSCC for short) is a non-contractible simple closed curve $\delta$ on $\Sigma_{g,1}$ such that $\Sigma_{g,1} \setminus \delta$ has two connected components and that bounds a properly embedded disk in $H_g$. For instance, a curve parallel to the boundary of $\Sigma_{g,1}$ is a CBSCC.

Combining the cited papers of Luft and Johnson we get that if $\beta, \beta'$ is a CBP then the map $T_\beta T_{\beta'}^{-1}$ belongs to $\mathcal{L}_{g,1} \cap \mathcal{T}_{B_{g,1}}$. We call such a map a $CBP$-twist, we also call the intersection group the Luft-Torelli group and we denote it by $\mathcal{LT}_{B_{g,1}}$.

In [8], Johnson proved that opposite twists around Bounding Pairs generate the Torelli group for $g \geq 3$. In this section we prove an analogous theorem for the Luft-Torelli group:

Theorem 10. The Luft-Torelli group $\mathcal{LT}_{B_{g,1}}$ is generated by CBP-twists.

4.1. Reduction to the closed case. The reduction to the closed case as many other results in this section are based on the following Lantern Relation, originally due to Dehn [3] and later rediscovered by Johnson [8].

Lemma 5 (Lantern Relation). Consider a 2-sphere with 4 holes (i.e. a lantern). Let the boundary components be $C_0, C_1, C_2, C_3$ and for $1 \leq i < j \leq 3$ denote by $C_{ij}$ a simple curve encircling $C_i$ and $C_j$ (see Figure 6). Then the following relation between Dehn twists holds:

$$T_{C_0} T_{C_1} T_{C_2} T_{C_3} = T_{C_{12}} T_{C_{13}} T_{C_{23}}.$$

Notice that once the four boundary circles are ordered the remaining curves and thus the Lantern Relation are determined.

Recall from Section [1] that the kernel of the map $\mathcal{M}_{g,1} \to \mathcal{M}_{g,*}$ is an infinite cyclic group generated by a Dehn twist along a curve $\delta$ parallel to the boundary and that this is a CBSCC. In particular the kernel is contained in $\mathcal{T}_{B_{g,1}}$. Moreover the action of this Dehn twist on the homology of the surface and also on the first homotopy group of the handlebody $H_g$ is trivial. As a consequence we have a short exact sequence:

$$1 \longrightarrow \mathbb{Z} \longrightarrow \mathcal{LT}_{B_{g,1}} \longrightarrow \mathcal{LT}_{B_{g,*}} \longrightarrow 1.$$

The three curves depicted in Figure 7 plus the boundary curve $\delta$ define a “Lantern” i.e. a 4-holed sphere on the surface $\Sigma_g$. Applying the lantern relation of Johnson (see Johnson [8]) one gets:

Lemma 6. The Dehn twist around $\delta$ can be written as a product of CBP-twists.
The group is given by sequence:

Chapter 3), denote this presentation by ral action of relations of the automorphism group of a free group on alphabet \( B \) generate \( \tilde{\eta} \) generate \( \tilde{\gamma} \).

Proposition 16. The group \( \mathcal{LT}B_{g,*} \) is generated by CBP-twists.

4.2. Strategy of the proof of Proposition 16 Recall from section 1.2 that we have two short exact sequences

\[
1 \longrightarrow \mathcal{L}B_{g,*} \longrightarrow B_{g,*} \longrightarrow \text{Aut } \pi_1(H_{g,*}) \longrightarrow 1
\]

\[
1 \longrightarrow \mathcal{TT}B_{g,*} \longrightarrow B_{g,*} \longrightarrow \text{GL}_g(\mathbb{Z}) \rtimes S_g(\mathbb{Z}) \longrightarrow 1.
\]

The map \( B_{g,*} \rightarrow \text{GL}_g(\mathbb{Z}) \) can be identified with the map given by the natural action of \( B_{g,1} \) on the first homology of \( H_{g,*} \). Therefore we have a short exact sequence:

\[
1 \longrightarrow \mathcal{LT}B_{g,*} \longrightarrow B_{g,*} \longrightarrow \text{Aut } \pi_1(H_{g,*}) \rtimes S_g(\mathbb{Z}) \longrightarrow 1.
\]

In [18] Nielsen gave an explicit finite presentation with four generators and 17 relations of the automorphism group of a free group on \( g \) generators (see also [14] Chapter 3), denote this presentation by

\[
\langle x_1, \ldots, x_4 \mid r_1, \ldots, r_{17} \rangle.
\]

The group \( S_g \) is free on \( \frac{g(g+1)}{2} \) generators, so we can find a presentation of the form

\[
\langle t_1, \ldots, t_{\frac{g(g+1)}{2}} \mid [t_i, t_j] \rangle,
\]

where \( [t_i, t_j] = t_i^{-1}t_j^{-1}t_i t_j \) and \( 1 \leq i, j \leq \frac{g(g+1)}{2} \). Let the action of \( \text{Aut } \pi_1(H_g) \) on \( S_g(\mathbb{Z}) \) be given by expressions of the form: \( x_i(t_j) = w_{ij} \) where \( w_{ij} \) is a word in the alphabet \( t_k \). Then a presentation of the semi-direct product \( \text{Aut } \pi_1(H_{g,1}) \rtimes S_g(\mathbb{Z}) \) is given by

\[
\langle x_1, \ldots, x_4, t_1, \ldots, t_n \mid r_1, \ldots, r_{17}, [t_i, t_j], x_k^{-1}t_i x_k w_k^{-1} \rangle,
\]

where \( 1 \leq k \leq 4 \) and \( 1 \leq i, j, l \leq \frac{g(g+1)}{2} \).

Assume that we have lifts of the generators \( \tilde{x}_i, \tilde{t}_j \) and that these lifts moreover generate \( B_{g,*} \). Then a set of normal generators of the group \( \mathcal{LT}B_{g,*} \) is given by the lifts of the relations \( \tilde{\eta}_i, [\tilde{t}_i, \tilde{t}_j], \tilde{x}_k^{-1}t_i \tilde{x}_k w_k^{-1} \) as words in the “lifted” alphabet.

In the mapping class group one has the well-known relation for Dehn twists \( \phi T_\gamma \phi^{-1} = T_{\phi(\gamma)} \). In particular as the image of a CBP by an element \( \phi \in B_{g,*} \) is
again a CBP, the group generated by the CBP-twists is normal in $B_{g,*}$. Therefore to prove Theorem 10 it is enough to prove Proposition 17.

Proposition 17. Under the above hypothesis the lifts

$$\tilde{r}_i, [\tilde{t}_i, \tilde{t}_j], \tilde{x}_k^{-1} \tilde{t}_i \tilde{x}_k \tilde{w}_kl \in \mathcal{LT}B_{g,*}$$

are products of CBP-twists.

Proof of Proposition 17.

It is a classical result of Nielsen [19] that a base-preserving mapping class is determined by its action on the fundamental group of the underlying surface. Geometric descriptions of generators for $B_{g,*}$ were given for instance by Suzuki [21] or Luft [12]. From their work we learn that we need one Dehn twist and 4 particular generators. Here we enlarge the list of Dehn twists to hit each one of the $g(g+1)$ generators needed for the group $S_g(\mathbb{Z})$.

4.2.1. Twist generators. We consider the $\frac{g(g+1)}{2}$ curves of Figure 8. The curve $B_{ij}$ for $i < j$ goes around the right foot of handles $i$ passes in front of handles $k$ for $i < k < j$ and goes around the left foot of handle $j$, the curve $B_{ii}$ is a meridian of handle $i$.

The corresponding Dehn twists will be denoted respectively $T_{ij}$ and $T_{ii}$. Notice that by construction the homology class of $B_{ij}$ is $b_{ij} = b_i - b_j$ and that of $B_{ii}$ is $b_{ii} = b_i$.

This twists belong to the Twist group $\mathcal{L}B_{g,*}$ and so act trivially on the homotopy group $\pi_1(\mathcal{H}_g)$. In particular the image of $T_{ij}$ in $\text{Aut} \ (\mathcal{H}_g) \ltimes S_g(\mathbb{Z})$ is $(0, t_{b_{ij}})$ where $t_{b_{ij}}$ denotes the transvection along the homology class $b_{ij}$. It is easily verified that these transvections freely generate the group $S_g(\mathbb{Z})$.

4.2.2. Non-twist generators. We will keep the names given to these maps by Suzuki in [21] but label them according to the generator of $\text{Aut}(\pi_1(\mathcal{H}_g))$ they hit (see [13 Corollary N1 p.164]). All elements of the basis of $\pi_1(\Sigma_g)$ that do not appear in the description of the action of a map fixed under the action. We denote by $\sigma_i$ the commutator $\alpha_i^{-1} \beta_i^{-1} \alpha_i \beta_i$.

(1) Cyclic translation of handles, $Q$. Action on homotopy:

$$\begin{align*}
\alpha_i &\mapsto \alpha_{i+1} \\
\beta_i &\mapsto \beta_{i+1}
\end{align*}$$

Indices are counted mod $g$.
(2) Twist of knob 1 $\sigma$. Action on homotopy:
\[
\begin{align*}
\alpha_1 & \mapsto \alpha_1^{-1}\sigma_1^{-1} \\
\beta_1 & \mapsto \sigma_1\beta_1^{-1}
\end{align*}
\]

(3) Interchange of knobs 1 and 2, $P$. Action on homotopy:
\[
\begin{align*}
\alpha_1 & \mapsto \sigma_1^{-1}\alpha_2\sigma_1 \\
\alpha_2 & \mapsto \alpha_1 \\
\beta_1 & \mapsto \sigma_1^{-1}\beta_2\sigma_1 \\
\beta_2 & \mapsto \beta_1
\end{align*}
\]

(4) Luft map $U$. This is a half twist that interchanges the curves $B_{22}$ and $B_{12}$, the boundaries of the two-holed torus which is the support of this map are $B_{11}$ and the curve $C$ depicted in Figure 9.

Action on homotopy:
\[
\begin{align*}
\alpha_1 & \mapsto \alpha_1\alpha_2 \\
\beta_1 & \mapsto \beta_1 \\
\alpha_2 & \mapsto \alpha_2^{-1}\beta_2^{-1}\alpha_2^{-1}\beta_2\alpha_2 \\
\beta_2 & \mapsto \alpha_2^{-1}\beta_2^{-1}\alpha_1^{-1}\beta_1\alpha_1\alpha_2
\end{align*}
\]

4.3. **Proof of proposition**

According to our strategy of proof we have to lift the relators $r_i, [t_{ij}, t_{kl}]$ and $r_i t_{kl} r_i^{-1} w_{ij}^{-1}$ to $B_{g,1}$ and show that these lifts are products of CBP-twists. We will deal successively with the twists relators $[t_{ij}, t_{kl}]$, the action realtors $x_i t_{kl} x_i^{-1} w_{ij}^{-1}$ and finally with the non-twist relators $r_i$.

Our main tool for recognizing elements that are products of CBP-twists is

**Lemma 7.** Let $\phi \in TB_{g,*}$ be a map. Assume that there exist $g$ disjoint disks $D_i$ properly embedded in the inner handlebody so that $H_g \setminus \bigcup_{i=1}^g D_i$ is a three ball and such that $\phi(D_i) = D_i$ for $1 \leq i \leq g$. Then $\phi$ is a product of CBP-twists.

**Proof.** Since $\phi$ acts trivially in homology it can not reverse the orientations of the boundaries of the discs and therefore we may assume that $\phi$ fixes the disc $D_i$ pointwise. In particular $\phi$ is in the image of the mapping class group relative to the boundary $M_{0,2g+1}$ of the $2g + 1$-holed 3-ball that is of the complementary of a small neighbourhood of the discs $D_i$. More precisely it is in the kernel of action on homology of this group. This mapping class group is well-known to be isomorphic to the framed pure braid group on $2g$ strands: $Z_{2g} \times P_{2g}$, where $P_{2g}$ denotes the pure braid group on $2g$ strands.

Without loss of generality we may assume that the discs $D_i$ are our preferred discs $B_{ii}$. Denote the left foot of the $i^{th}$ handle by $i_0$ and the right foot by $i_1$. 

![Figure 9. Luft map](image-url)
Then the group $M_{0,2g}$ is generated by the following Dehn twists:

1. Twists along the curves $A_{i_0i_1}$ (resp. $A_{i_1i_1}$) which go to the left (resp.) right foot.
2. Twists along the curves $A_{i_0i_1}$ that enclose the two feet of the $i^{th}$ handle.
3. Twists the curves $A_{i_0j_0}, A_{i_0j_1}, A_{i_1j_0}, A_{i_1j_1}$ for $i < j$ (see Figure 10).

Notice that the twists around $A_{i_0j_1}$ is our preferred Dehn twist $T_{ij}$

If we project compute the action of homology of these twists we get a surjective map $\mathbb{Z}^{2g} \times P_{2g} \to S_g(\mathbb{Z})$ and in terms of the images $\overline{A}_{i,j}$ of the above generators a complete set of generators is given by:

1. $\overline{A}_{i_0i_1} = 1, \overline{A}_{i_0j_1} = \overline{A}_{i_1j_0}, \overline{A}_{i_1j_1} = \overline{A}_{i_0j_0}, \overline{A}_{i_0j_0} = \overline{A}_{i_1j_0} \overline{A}_{i_1j_0}^{-1} \overline{A}_{j_0j_0}$
2. $[\overline{A}_{i_0j_1}, \overline{A}_{i_0k_1}] = 1, [\overline{A}_{i_0j_1}, \overline{A}_{i_1k_0}] = 1, [\overline{A}_{i_1i_0}, \overline{A}_{j_0j_0}] = 1$.

Notice that the first series of relations simply reduce the number of relators and the second series is the standard presentation of the free abelian group on the remaining relators.

The kernel of the map $M_{0,2g} \to \text{Aut}(H)$ is therefore normally generated by the lifts of the above relations that are not relations in $M_{0,2g}$. We now prove that these lifts as maps in $\mathcal{TB}_{g,1}$ are products of CBP-twists.

There are only three relations in the above list that do not lift obviously to either a relation or a product of CBP-twists.

1. Relation $\overline{A}_{i_0i_1}$. The twists $A_{i_0i_1}$ are non-trivial mapping classes. For $i = 1$, applying the Lantern Relation determined by the four curves in Figure 11 we can express $A_{1_01_1}$ as a product of CBP-twists. Similar computations hold for the $g-1$ other cases.
Lifts of action relators.

4.3.2. Lifts of twist relators.

Conjugation in one checks directly that the lifts leave the curves around the curves $\sigma(1)$.

The relation $A_{i_0j_0} = A_{i_0j_0}^2 A_{i_1j_1}^{-1} A_{j_0j_0}^2$. We may find a contractible simple closed curve $A'_{i_0j_1}$ that encloses the foots $A_{i_0j_0}, A_{i_1j_0}, A_{j_0j_0}$ defining a Lantern and does not intersect the curves $A_{i_0j_0}$ and $A_{i_1j_0}$. Applying the Lantern relation one finds:

$$T_{A_{i_0j_0}} T_{A_{i_1j_0}} T_{A_{i_0j_0}}^{-2} T_{A_{j_0j_0}} = T_{A_{i_0j_1}} T_{A_{i_0j_0}} T_{A_{j_0j_0}}^{-1} T_{A_{i_0j_0}}^{-1} T_{A_{i_1j_1}}.$$

And this is a product of CBP-twists.

(3) The relation $[A_{i_0j_1}, A_{k_0l_1}] = 1$ when the curves $A_{i_0j_1}$ and $A_{k_0l_1}$ intersect non-trivially. By definition of the curves this happens if and only if $i < k < j < l$.

The relation lifts to $T_{T_{A_{i_0j_1}}(A_{k_0l_1})} T_{A_{k_0l_1}}$. As the homology classes of curves $A_{i_0j_1}$ and $A_{k_0l_1}$ both belong to the Lagrangian $B$, one checks that $T_{A_{i_0j_1}}(A_{k_0l_1})$ is homologous to $A_{k_0l_1}$. In particular the lift is almost a CBP-twists except that the underlying curves intersect. It is enough to find a third curve $A'_{k_0l_1}$ disjoint from $A_{i_0j_1}$ and $A_{k_0l_1}$, contractible in the inner handlebody and homologous to $A_{k_0l_1}$, for then it will be also disjoint from $T_{A_{i_0j_1}}(A_{k_0l_1})$ and we will have

$$T_{T_{A_{i_0j_1}}(A_{k_0l_1})} T_{A_{k_0l_1}} = T_{T_{A_{i_0j_1}}(A_{k_0l_1})} T_{A_{k_0l_1}} T_{A_{k_0l_1}}^{-1} T_{A_{k_0l_1}},$$

a product of CBP-twists. This is done by using curves that go “through the handles”, see Figure 12 for the case $(i_0, j_1 k_0, l_1) = (1, 3, 2, 4)$.

\[ \square \]

4.3.1. Lifts of twist relators. One checks that he lifts of the relators $[t_{ij}, t_{kl}]$ all leave the curves $B_{ii}$ 1 \leq i \leq g invariant and we may apply Lemma 4.

4.3.2. Lifts of action relators. Recall that the generators $t_{ij}$ lift to Dehn twists around the curves $B_{ij}$ and that the lift of the action of the generators $Q, \sigma, P, U$ is conjugation in $B_{g,1}$, by the corresponding map. For each of the following relations one checks directly that the lifts leave the curves $B_{ii}$ invariant and therefore we may apply in each case Lemma 4.

1. Action of $Q$. The relations to lift are all of the form $Q(t_{ij}) = t_{i+1,j+1}$ (indices mod $g$).

2. Action of $\sigma$. Relations are of the form $\sigma(t_{ii}) = t_{i-1}^{-1} t_{j-1} t_{ii} t_{ij}^{-2}$ for $1 < i < j$ and $\sigma(t_{11}) = t_{11}$.

3. Action of $P$. Relations are $P(t_{11}) = t_{22}$, $P(t_{22}) = t_{11}$, $P(t_{ii}) = t_{2i}$ for $i \geq 3$, $P(t_{ii}) = t_{11}$ for $i \geq 3$. All other generators are fixed.
(4) Action of $U$. Relations are $U(t_{22}) = t_{12}$, $U(t_{12}) = t_{22}$, $U(t_{2i}) = t_1 t_{12} t_{11}^{-1}$ for $i \geq 3$. All other generators are fixed.

4.3.3. Lifts of non-twists relators. Instead of using a case-by-case check we use the following rephrasing of a result of Hirose (see [7, Theorem B∗] and the description of generators therein):

Proposition 18. The kernel of the map $AB_{g,*} \to \text{Aut} \pi_1(H_g)$ is generated by maps which have the following property:

There exist $g$ properly embedded discs $D_1, \ldots, D_g$ in $H_g$ such that $H_g \setminus (D_1 \cup \ldots \cup D_g)$ is a 3-ball and such that the map fixes the boundaries of the discs (up to isotopy).

In view of Lemma 7 the maps described in the above Proposition are all products of CBP-twists.

Consider any relation $r$ among the generators of $\text{Aut} \pi_1(H_g)$. Since our lifts of the generators of $\text{Aut} \pi_1(H_g)$ all belong to $AB_{g,*}$ the lift $\tilde{r}$ of $r$ belongs to the kernel of the map $AB_{g,*} \to \text{Aut} \pi_1(H_g)$. Therefore by the above Proposition 18 and by Lemma 7, the lift $\tilde{r}$ is a product of CBP-twists.

This ends the proof of Proposition 17.
