Selection of Fungal Strains

Bolinea lutea strains F23523 and F24150 were obtained as a gift from Novartis, Switzerland in 2007. Two strains of Strobilurus tenacellus, one gifted by Prof. Zeeck in Germany and other obtained from CBS-KNAW, Fungal Diversity Centre, Netherland were selected for preliminary screening.

Strobilurus tenacellus: Maintenance and Fermentation

S. tenacellus culture was received on malt extract agar (MEA) medium in a glass ampule. For maintenance it was transferred to an agar plate on MEA medium (50 g·L⁻¹ water). The strain grew well on the agar plates and was inoculated into liquid shake flask culture in M2 medium (10 g malt extract, 4 g yeast extract, 4 g glucose L⁻¹) as seed culture and incubated for 5 days at 22 °C and 150 rpm. Production cultures in MEA medium (150 mL) in 500 mL conical flask were inoculated with the seed culture (10 mL) and grown at 22 °C and 150 rpm. After 7-10 days of shake flask incubation the liquid culture was collected and filtered under vacuum.

Bolinea lutea: Agar Plate Preparation and Storage

Both strains of B. lutea were preserved as frozen culture. They were grown on agar plates on YGM medium containing yeast extract (0.4%), glucose (0.4%) and malt extract (1%) in water supplemented with 2% each of oatmeal and agar. The autoclaved agar solution was then melted in a microwave and poured into sterile petri dishes. A sterile loop was used to inoculate the agar plates from the frozen glycerol stock culture. The plates were left to grow at 25 °C for 5 days or when a substantial amount of biomass is spread throughout the plate. The mature agar slants could either be used to inoculate seed culture or stored for future use (viable up to 6 months in refrigerator at 4 °C). For long storage the mycelia from mature plates were also
transferred to a sterile solution of 20% w/v glycerol in water and stored in 1.5 mL pre-sterilized vial at -80 °C.

**Bolinea lutea: Seed Culture Preparation**

An aqueous medium consisting of 3% glucose, 1% maltose, 0.4% yeast extract and 2% oatmeal was prepared in 100 mL in 250 mL conical flask. The flasks were plugged with a foam bung and capped with aluminium foil prior to autoclave sterilization. It was then inoculated with the mycelia (1/4th portion of one mature agar plate) and then incubated for 3-5 days on a rotary shaker at 25 °C and 150 rpm until a well grown mass of fungi was achieved.

**B. lutea: Production Culture Preparation**

The production medium consists of 3% glucose, 1% malt extract, 0.4% yeast extract and 2% oatmeal in water. The pH was adjusted to 7.5 with dil. NaOH solution before sterilization. Transferred 150 mL to a 500 mL flask and inoculated with 10 mL of seed culture under aseptic conditions and cultivated for 7-10 days at 25 °C, 150 rpm.

**Optimisation of Culture Conditions**

To overcome initial production problem optimization of fermentation conditions was carried out for enhancing strobilurin production. Five different media were tested: glucose nutrient broth (GNB); malt extract broth (MEB); yeast extract, glucose, malt extract, (YGM); complete medium broth (CMB); and potato dextrose broth (PDB). GNB medium was selected for future work for its better yield. Variation in pH of production medium before inoculation was also checked. pH 4-9 by the addition of dil. NaOH or HCl was adjusted. Fungi were grown in baffled flasks and the metabolite profile was compared to see the effect of aeration. Different sets of temperature (20-37 °C) and shaking (50-250 rpm) were also evaluated.

**Extraction of Metabolites and LCMS Analysis**

**Strobilurus tenacellus**

A 1 L *S. tenacellus* culture after 10 days of fermentation was filtered using vacuum and washed several times with distilled water. The wet cells (31 g) were extracted with MeOH/Acetone (2:1) and then with MeOH. The combined extracts were evaporated to remove most of the acetone and the metabolites were extracted with 100 mL CHCl₃ from the residue. The organic extract was dried over anhydrous MgSO₄ filtered and evaporated in vacuo, yielding 500 mg of dark brown oil. The crude extract solution (10 mg·mL⁻¹ in MeOH) was first centrifuged to remove solids and then subjected to LCMS analysis.

**Bolinea lutea**

The whole cell 1 L culture (7-10 days) was homogenized and a 0.5 L solution of MeOH/EtOAc (3:2) was added to the extract overnight. Filtration under vacuum, and the filtrate was concentrated in vacuo. The concentrate was again extracted with CHCl₃ (3 × 150 mL). The organic solvents were dried over anhydrous MgSO₄ and evaporated in vacuo. The extract was dissolved in acetonitrile and extracted with petroleum ether (2 × 100 mL) to remove fatty acids. The defatted acetonitrile extract was dried to give 600 mg of yellow oil.

**LCMS Analysis**

A solution of the crude extract (10 mg·mL⁻¹) was prepared in HPLC grade MeOH and centrifuged for removal of solids. 50 µL of this solution was injected to a Phenomenex Luna 5µ C₁₈ (II) (250 × 4.6 mm) reversed phase column. A solvent system of MeOH (B) and water (A) with 0.05% formic acid each was used. The sample was run for one hour program (0-5 min: 75% A, 25% B; 5-51 min: 5% A, 95% B; 51-53 min: 5% A, 95% B; 53-55 min: 75% A, 25% B; 55-60 min: 75% A, 25% B), at 1 mL·min⁻¹ flow rate.

**Preparative Thin Layer Chromatography and isolation for isolation of Strobilurin A and B**
Crude *B. lutea* extract (50-70 mg) was loaded on a silica gel coated TLC glass plate (20 × 20 cm). The plate was developed with 10% EtOAc in petroleum ether (4 consecutive elutions) to afford 5 bands. A yellow pure band at Rf 0.84 corresponded to strobilurin A 2, while strobilurin B 3 appeared at Rf 0.56 as a bright yellow band. Strobilurin H 45 is a minor metabolite which appeared in mixture with strobilurin B 3 which could not be separated by preparative TLC. The target bands were carefully scraped off and extracted with EtOAc for further characterization.

Time Course Production Studies.
30 conical flasks (500 ml) each containing the production media (150 ml) were inoculated with mycelia from the seed culture (10 ml). The flasks were shaken at room temperature and 150 rpm. Each day one flask was collected and extracted following the standard protocol. The crude extract obtained from the B. lutea whole culture from each flask was weighed and dissolved in 3 mL MeOH. The solution was centrifuged for removal of solids. 50 µL of this solution was injected to the LCMS, a Phenomenex Luna 5µ C₁₈ (II) (250 × 4.6 mm) reversed phase column. A solvent system of CH₃CN (B) and water (A) with 0.045% trifluoroacetic acid was used. The sample was run for one h program (0-5 min: 75% A, 25% B; 5-51 min: 5% A, 95% B; 51-53 min: 5% A, 95% B; 53-55 min: 75% A, 25% B; 55-60 min: 75% A, 25% B), at flow rate of 1 mL-min⁻¹.

A series of known concentrations of strobilurin A, B, G, and H (0.03-1 mg·mL⁻¹ in MeOH) were detected by diode array detector (200-400 nm). Calibration curves were plotted by area under HPLC peaks vs. a series of standard of known strobilurin concentrations. Crude extraction method was used to identify the compounds via LCMS analysis (retention times, UV characteristics and ESI-MS) and then peak integrations were performed to compare peak area with the corresponding standard curves for quantification.

General Procedure for Precursor Feeding
Conical flasks (500 ml), each containing 150 mL of the specified production medium were inoculated with the mycelia from the seed cultures (5-10 mL) as described earlier. The flasks were incubated at 25 °C and 150 rpm in a shaker. The selected proposed precursors were supplied as a pulse feed on days 2, 3 and 4 of cultivation as MeOH or DMSO solution. Controls in parallel were run with each experiment for systematic comparison. After fermentation for an appropriate duration the flasks were collected for extraction. Metabolites of interest were isolated following standard protocol.

Feeding and Incorporation of [2, 3-13C₂]-Cinnamic Acid (23) and thiolester (24).
Following the above procedure [2, 3-13C₂]-cinnamic acid and its SNAC thiolester were fed separately to the cultures of B. lutea as MeOH solution (0.05 mM). After 8-10 days of cultivation LCMS screening of the crude extract found all observed strobilurins enriched with precursors identified by their difference in m/z value as compared to control. The two major enriched metabolites eluting at Rt 41.7 min and 43.5 min were purified by preparative HPLC. Their structures were confirmed as strobilurin A and strobilurin B by NMR spectroscopy. The 13C NMR signals at 131.3 and 130.3 ppm respectively showed incorporations of 70%.

Feeding of (2Z, 4E) 3-Fluorophenyl -2-methylpentadienoic Acid 26 SNAC Thiolester 27.
Following the standard feeding procedure and it SNAC were fed to the *B. lutea* culture (150 mL) and was extracted accordingly after 7-10 days of cultivation. LCMS analysis confirmed that 3-fluorostrobilurin A was not produced in either case.

**Feeding of (2E, 4Z, 6E)-3-fluorophenyl-4-methylheptatrienoic acid (30) and thiolester (31)**

(E,Z,E) 3-fluorophenyl-4-methylheptatrienoic acid 30 and its SNAC thiolester were fed to the *B. lutea* culture (150 mL) and was extracted accordingly after 7-10 days of cultivation. LCMS analysis confirmed that 3-fluorostrobilurin A was not produced in either case.

Feeding of (E,Z,E)-3-fluorophenyl-4-methylheptatrienoic acid (30) and thiolester (31) was fed to *B. lutea* following the above feeding procedures. After 8-10 days of fermentation the culture was extracted accordingly. The crude extract was centrifuged and then subjected to LCMS analysis. Initial LCMS analysis suggested that a new peak eluted at 23.1 min with difference of 18 in m/z value from natural analogue strobilurin A. The peak was targeted for purification using the method above. The structure was confirmed as 3-fluorostrobilurin A by 1D, 2D NMR and HRMS investigations.

**Production of [14-C2H3]-3-Fluorostrobilurin A**

Following the procedure, (E,Z,E) [4-C2H3]-3-fluorophenyl-4-methylhepta-trienoic acid 30, was fed to *B. lutea* (500 mL culture) at a concentration of 100 mg·L⁻¹. The cultures were allowed to grow for 8-10 day at 25 °C and 150 rpm. The culture was collected and extracted using the standard procedure. The crude extract was dissolved in HPLC MeOH (10 mg·mL⁻¹) and centrifuged to remove solids before injection. 50 µL of this solution was injected for LCMS analysis. Initial analysis showed a new peak eluted at 24.2 min. The new peak was isolated as a mixture with strobilurin A (1:3). Repurification afforded a mixture of enriched-compound and strobilurin A again in 3:2 ratio (0.9 mg). The mixture was subjected to spectroscopic analysis and the structure was confirmed as [14-2H3]-3-fluorostrobilurin A: λ max (MeOH) = 219, 300 nm; δ H (600 MHz, CD3OD): 1.90 (s, 3H, CH3), 3.70 (s, 3H, 15-OCH3), 3.84 (s, 3H, 16-OCH3), 6.18 (d, J 11.0, 1.5 Hz, 1H, 9-H), 6.55 (d, J 16 Hz, 1H, 7-H), 6.60 (dd, J 11.0, 16.0 Hz, 1H, 8-H), 7.01 (ddd, J 11.2, 8.0, 5.5 Hz, 1H, 3-H), 7.08 (td, J 8.0, 1.0 Hz, 1H, 5-H), 7.17 (ddddd, J 8.0, 8.0, 5.5, 2.0 Hz, 1H, 4-H), 7.41 (td, J = 8.0, 2.0 Hz, 1H, 6-H), 7.51 (s, 12-H) ppm. δ C (125 MHz) 23.8 (C-14), 51.5 (15-OCH3), 61.7...

2. Synthesis of intermediates

General Synthetic and Analytical Details

Commercially available compounds were used without further purification except where stated. Experiments which included moisture or air sensitive reactions were carried out in flame-dried glassware under a positive pressure of nitrogen using standard syringe/ septa techniques. Anhydrous solvents dichloromethane and tetrahydrofuran were obtained by passing through a modified Grubbs system of alumina columns, manufactured by Anhydrous Engineering. Petroleum ether is of the 40-60 °C boiling point range. Routine monitoring of reactions was performed using precoated Merck-Keiselgel 60 F254 aluminium backed T.L.C. plates. The spots were visualised by UV 254 light, or potassium permanganate. Flash column chromatography was performed using silica gel (40-63 micron, obtained from Fluorochem Ltd.) as the adsorbent and carried out according to the procedure outlined by Still et al.$^1$ Melting points were determined on an Electrothermal IA6301 melting point apparatus and are uncorrected. Infrared (IR) spectra were recorded on a Perkin Elmer Spectrum One FT-IR spectrometer as either a neat solid or liquid.$^1$ $^1$H, $^{13}$C and CRAPT NMR spectra were recorded as solution in CDCl$_3$ unless stated otherwise. The spectra were recorded on a lambda 300 MHz, varian 400 MHz or a Jeol Eclipse 400 MHz spectrometer. The chemical shifts ($\delta$) are reported in parts per million (ppm) and the coupling constants ($J$) are in Hertz (Hz). Electrospray (ESI) mass spectra were recorded on a Bruker Daltonics Apex 4e 7.0T FT-MS mass spectrometer. Methane was the ionised gas used for the chemical ionisation. Unless stated, data for all known compounds are in agreement with published data.

Freshly prepared N-acetylcysteamine (0.27 g, 2.27 mmol) in dry CH_2Cl_2 (15 mL) was stirred at 0 °C under an atmosphere of nitrogen. DCC (0.36 g, 1.80 mmol) in dry CH_2Cl_2 (3 mL) was added followed by DMAP (0.009 g, 0.06 mmol). The solution was left at 0 °C for 2 h and was allowed to warm to room temperature overnight. The reaction was subsequently quenched with saturated aq. Ammonium chloride solution (150 mL) and was extracted with CH_2Cl_2 (3 × 300 mL). The combined organic extracts were dried over magnesium sulphate. The solution was then filtered and concentrated \textit{in vacuo} to yield a white solid. Ethyl acetate (5 mL) was added to dissolve the product and the insoluble urea by-product was then filtered off. 4-Methyl hexa-2, 4-dienoic acid (61)

To a solution of triethyl-2-phosphonopropionate (10.6 g, 47.30 mmol) in hexane (90 mL) was added n-butyllithium (n-BuLi) (1.0 M solution in hexane, 47 mL) drop wise at room temperature. The resulting mixture was stirred at the same temperature for 30 min. Trans-2-methyl-2-butenal (4.2 mL, 49.9 mmol) was added drop wise to the mixture at 0 °C, and stirring was continued for 30 min at room temperature. After quenching the reaction by adding water (50 mL) the mixture was extracted with hexane (3\times50mL). The organic extracts were combined, dried over anhydrous Na_2SO_4, filtered...
