Abstract: Desulfurized gypsum (DG) as a soil modifier imparts it with bulk solid sulfite. The Fe(III)–sulfite process in the liquid phase has shown great potential for the rapid removal of As(III), but the performance and mechanism of this process using DG as a sulfite source in aqueous solution remains unclear. In this work, employing solid CaSO3 as a source of SO32−, we have studied the effects of different conditions (e.g., pH, Fe dosage, sulfite dosage) on As(III) oxidation in the Fe(III)–CaSO3 system. The results show that 72.1% of As(III) was removed from solution by centrifugal treatment for 60 min at near-neutral pH. Quenching experiments have indicated that oxidation efficiencies of As(III) are due at 67.5% to HO•, 17.5% to SO5•− and 15% to SO4•−. This finding may have promising implications in developing a new cost-effective technology for the treatment of arsenic-containing water using DG.

Keywords: desulfurized gypsum; Fe(III); CaSO3; As(III); resource utilization

1. Introduction

The wet desulfurization process has significant advantages of fast reaction and high efficiency, and has been widely used in China. However, desulfurized gypsum (DG) cannot be fully utilized, and its disposal constitutes a waste of resources [1,2]. Currently, DG is mainly used as a soil conditioner [3], serving to improve certain properties of soil, such as its pH, water absorption, water retention, and so on. The potential oxidative ability of DG towards heavy metals or organic pollutants in soil-containing transition metals has rarely been reported [4–7].

Recently, several investigations have shown that sulfate radical (SO4•−)-based advanced oxidation processes work well for the removal of organic and inorganic pollutants in groundwater and wastewater treatment [8–10]. The commonly used oxidants include persulfate (PS), peroxymonosulfate (PMS), and sulfite. Compared to PS and PMS, sulfite has significant advantages of low toxicity, low cost, and easy preparation, thus making it both environmentally friendly and economic [11]. Transition metal systems, such as Fe(II/III), have been reported to activate sulfite, such that it has a good oxidation effect on arsenic and organic pollutants in water [12–16]. Additionally, iron-based nanomaterials of high superficial activity also had a good effect on removing heavy metal pollutants in the environment [17,18]. In the Fe(II/III)-sulfite system, S(IV) can be catalytically oxidized under certain conditions to produce a series of oxysulfur species, including sulfite radical (SO3•−) and sulfate radical (SO4•−) [19–21]. An intrinsic mechanism has been proposed for this system, which includes the following reactions (Equations (1)–(8)) [22–26]:

\[ \text{Fe}^{2+} + \text{HSO}_3^- \rightarrow \text{FeH} \text{SO}_3^+ \] (rapid equilibration) (1)
4FeHSO$_3^+$ + O$_2$ → 4FeSO$_3^+$ + 2H$_2$O \hspace{1cm} (2) \\
FeSO$_3^+$ → Fe$^{2+}$ + SO$_3^{2-}$ \hspace{1cm} (3) \\
SO$_3^{2-}$ + O$_2$ → SO$_5^{•−}$ \hspace{1cm} (4) \\
SO$_5^{•−}$ + HSO$_3^−$ → SO$_3^{−}$ + HSO$_5^−$ \hspace{1cm} (5) \\
Fe$^{2+}$ + HSO$_5^−$ → SO$_4^{•−}$ + Fe$^{3+}$ + OH$^{−}$ \hspace{1cm} (6) \\
Fe$^{3+}$ + HSO$_3^−$ = FeSO$_3^+$ + H$^+$ (log$k_7$ = 2.45) \hspace{1cm} (7) \\
SO$_5^{•−}$ + HSO$_3^−$ → SO$_5^{2−}$ + SO$_3^{•−}$ + H$^+$ \hspace{1cm} (8) \\

In actual application processes, soluble SO$_4^{2−}$ is consumed very rapidly. Due to the slow dissolution of solid CaSO$_3$, the concentration of soluble SO$_4^{2−}$ in the solution can keep in an appropriate range [27]. Although Fe(II) activated homogeneous sulfite has been fully studied and reported, the activation mechanism of heterogeneous calcium sulfite remains unclear. In summary, it was necessary to research and develop new utilization methods of calcium sulfite waste.

In this work, CaSO$_3$ has been directly employed as a sulfite donor to assess the oxidation capability of the Fe(III)–sulfite system. The effects of CaSO$_3$/Fe(III) concentration, pH, and initial concentrations of As(III) have been investigated. Free radical quenching experiments were then performed to determine the contributions of reactive species in this system. Our work may contribute to an understanding of the main mechanisms of As(III) removal using the iron–CaSO$_3$ system and provide a theoretical basis for the use of desulfurized gypsum as a soil conditioner.

2. Results and Discussion

2.1. Control Experiments

As shown in Figure 1, As(tot) remained unchanged in both the control experiments and the Fe(III)-CaSO$_3$ system experimental group, so the degradation of As(III) was due to the conversion to As(V) by oxidation reaction. The deployment of Fe(III) or CaSO$_3$ alone led to 20% degradation of As(III) in 1 h, which is in obvious contrast to the combination of Fe(III) and CaSO$_3$ (72%).

Fe(III) in the solution mainly existed in the form of colloid at near-neutral pH and thus adsorbed As(III) through surface complexation. As(III) can then be oxidized by electron transfer from As(III) to Fe(III) induced by radiation absorption via ligand-to-metal charge transfer [28]. The decrease in As(III) concentration in the presence of Fe(III) in the absence of sulfite may be due to radical oxidation pathway of As(III) and adsorption on colloidal ferric hydroxides followed by oxidation [19]. The decrease in As(III) concentration in the presence of sulfite alone may be due to the auto-oxidation reaction of SO$_3^{2−}$ on the surface of CaSO$_3$ solid surface (>Ca(II)-SO$_3^{2−}$ in Equations (9)–(13)) and the co-oxidation of SO$_3^{2−}$ with As (III) under alkaline conditions on the surface of the CaSO$_3$ solid (Equations (14) and (15)).

>CaSO$_3$ → >Ca(II)-SO$_3^{2−}$ \hspace{1cm} (9) \\
>Ca(II)-SO$_3^{2−}$ + O$_2$ → >Ca(II)-SO$_3^{2−}$-O$_2$ \hspace{1cm} (10) \\
>Ca(II)-SO$_3^{2−}$-O$_2$ → >Ca(II)-SO$_4^{•−}$ + O$_2^{•−}$ \hspace{1cm} (11) \\
>Ca(II)-SO$_4^{•−}$ + O$_2$ → >Ca(II)-SO$_5^{•−}$ \hspace{1cm} (12) \\
>Ca(II)-SO$_5^{•−}$ + As(III) → >Ca(II)-As(V) + SO$_4^{2−}$ \hspace{1cm} (13) \\
>CaSO$_3$ + H$_2$O → >Ca(II)-OH$^{−}$ + SO$_3^{2−}$ + H$^+$ \hspace{1cm} (14) \\
>Ca(II)-OH$^{−}$ (mediated reaction): SO$_3^{2−}$ + As(III) + O$_2$ → SO$_4^{2−}$ + As(V) \hspace{1cm} (15) \\

When Fe(III) and CaSO$_3$ solid powders were added simultaneously, the reaction rate of the system increased rapidly. This is basically consistent with the previous research results
on the Fe(III)-sulfite system [14,20,21], suggesting that the activation of $SO_3^{2-}$ may occur either in the liquid phase or on the surface of CaSO$_3$ particles (Equations (16) and (17)). Considering that irons can easily form hydroxide precipitates at near neutral pH and aggregate with CaSO$_3$ to form composite particles, the activation of $SO_3^{2-}$ on the solid surface may also be important.

$$>\text{Ca(II)}-\text{SO}_3^{2-} + \text{Fe(III)} \rightarrow >\text{Ca(II)}-\text{SO}_3^{2-}-\text{Fe(III)}$$

(16)

$$>\text{Ca(II)}-\text{SO}_3^{2-}-\text{Fe(III)} \rightarrow >\text{Ca(II)}-\text{SO}_5^{2-} + \text{Fe(II)}$$

(17)

![Figure 1. Concentration changes of As(III) and As(tot) in the control experiments of Fe(III)-CaSO$_3$ system. Initial conditions: [Fe(III)] = 0.5 mM, [CaSO$_3$] = 5 mM, [As(III)] = 5 µM, pH 6.0, air bubbling at 0.5 L min$^{-1}$.

2.2. Effects of Fe(III) and CaSO$_3$ Dosages on As(III) Oxidation

The effects of Fe(III) and CaSO$_3$ dosages on As(III) oxidation were investigated (Figure 2). For optimizing Fe(III) dosage, 0.5 mM Fe(III) achieved the best As(III) oxidation. When Fe(III) concentrations exceed this value, As(III) oxidation was conversely inhibited. This can be explained by the fact that a greater amount of Fe(OH)$_3$ colloid might be produced in the reaction system, which would inhibit the dissolution and release of CaSO$_3$ and the activation ability of Fe(III) towards HSO$_3^-$. Besides, a large amount of Fe(II) generated by the initial reactions (Equations (1)–(3)) could also consume $SO_5^{2-}/SO_4^{2-}$ in the solution (Equations (18) and (19)). However, due to the presence of excess CaSO$_3$, HSO$_3^-$ continues to slowly dissolve, and the oxidation efficiency of As(III) does not decrease steadily with the increase in Fe(III) concentration. Hence, Fe(III) concentration should not be the only limiting factor for As(III) oxidation in the Fe(III)-CaSO$_3$ system.

$$SO_5^{2-} + Fe^{2+} + H^+ \rightarrow HSO_3^- + Fe^{3+}$$

(18)

$$SO_4^{2-} + Fe^{2+} \rightarrow SO_4^{2-} + Fe^{3+}$$

(19)
and aggregate with CaSO₃ to form composite particles, the activation of SO₃²⁻ on the solid surface may also be important.

\[
\text{Ca}^{2+} + \text{SO}_3^{2-} + \text{Fe}^{3+} \rightarrow \text{Ca}^{2+} + \text{SO}_3^{2-} - \text{Fe}^{3+} \quad (16)
\]

\[
\text{Ca}^{2+} + \text{SO}_3^{2-} - \text{Fe}^{3+} \rightarrow \text{Ca}^{2+} + \text{SO}_4^{2-} + \text{Fe}^{2+} \quad (17)
\]

2.2. Effects of Fe(III) and CaSO₃ Dosages on As(III) Oxidation

The effects of Fe(III) and CaSO₃ dosages on As(III) oxidation were investigated (Figure 2). For optimizing Fe(III) dosage, 0.5 mM Fe(III) achieved the best As(III) oxidation. When Fe(III) concentrations exceed this value, As(III) oxidation was conversely inhibited. This can be explained by the fact that a greater amount of Fe(OH)₃ colloid might be produced in the reaction system, which would inhibit the dissolution and release of CaSO₃ and the activation ability of Fe(III) towards HSO₃⁻. Besides, a large amount of Fe(II) generated by the initial reactions (Equations (1)–(3)) could also consume SO₅²⁻/SO₄²⁻ in the solution (Equations (18) and (19)). However, due to the presence of excess CaSO₃, HSO₃⁻ continues to slowly dissolve, and the oxidation efficiency of As(III) does not decrease steadily with the increase in Fe(III) concentration. Hence, Fe(III) concentration should not be the only limiting factor for As(III) oxidation in the Fe(III)-CaSO₃ system.

\[
\text{SO}_5^{2-} + \text{Fe}^{2+} + \text{H}^+ \rightarrow \text{HSO}_5^- + \text{Fe}^{3+} \quad (18)
\]

\[
\text{SO}_4^{2-} + \text{Fe}^{2+} \rightarrow \text{SO}_4^{2-} + \text{Fe}^{3+} \quad (19)
\]

Meanwhile, for optimizing CaSO₃ dosages, 30 mM CaSO₃ achieved the best As(III) oxidation. When CaSO₃ concentration exceeds this value, the concentration of S(IV) is much higher than that of As(III) in the solution and As(III) oxidation was inhibited. The reasons for the inhibition of As(III) oxidation may be that S(IV) on the surface of CaSO₃ may compete with As(III) for SO₄²⁻ [Equation (20)]. Therefore, the removal of SO₄²⁻ by excess S(IV) may be a reason for the inhibition of As(III) oxidation. Zhou et al. [18] delineated the reactions of SO₅²⁻/SO₄²⁻ in the Fe(III)–S(IV) system, indicating that an excess of S(IV) or Fe(II) may inhibit the reactions of SO₅²⁻/SO₄²⁻. At the same time, excess CaSO₃ may lead to a large number of particles around Fe(III), which would inactivate it and reduce its ability to activate S(IV).

\[
\text{SO}_4^{2-} + \text{HSO}_3^- \rightarrow \text{HSO}_4^- + \text{SO}_3^{2-} \quad (20)
\]

2.3. Effect of pH on As(III) Oxidation

To investigate the effect of pH on the Fe(III)-CaSO₃ system, experiments were conducted at pH 4, 6, 8, and 10 (Figure 3). It was found that As(III) oxidation efficiency varied from 63% at pH 10 to 80% at pH 4 within 60 min and when at pH 6 and 7, the efficiency of the system had no obvious difference, reaching about 75%.

Figure 2. Effect of dosage of Fe(III)/CaSO₃ on the oxidation efficiency of As(III) in the Fe(III)-CaSO₃ system after a reaction time of 60 min. Initial conditions: [As(III)] = 5 μM, pH 6.0, air bubbling at 0.5 L min⁻¹. Fe(III) + 5 mM CaSO₃: [Fe(III)] = 0.1–2.0 mM, [CaSO₃] = 5 mM; CaSO₃ + 0.5 mM Fe(III): [Fe(III)] = 0.5 mM, [CaSO₃] = 0–40 mM.
Lower pH values led to more efficient As(III) oxidation, consistent with conclusions drawn for the Fe(III)-Na₂SO₃ system [12]. This may be because, at near-neutral pH, the Fe in the solution mainly exists in the form of Fe(OH)²⁺ or Fe(OH)₃, and forms a complex with sulfite [19]. Fe(III) and Fe(II) in the reaction solution can be rapidly converted, according to Equations (3) and (7), which is also a key step affecting the reaction rate in the Fe(III)-Na₂SO₃ system. When the pH approaches alkaline, the system still maintained good oxidation efficiency, probably because the interconversion of SO₄•⁻ to HO• (Equation (21)) is favored at pH > 8.5 and the direct activation of sulfite by alkalion [29].

$$\text{SO}_4^{\cdot-} + \text{OH}^- \rightarrow \text{SO}_4^{2-} + \text{HO}^\bullet \text{ (alkaline pH)} \quad (21)$$

2.4. Effect of the Initial Concentration of As(III) on Its Oxidation

As(III) oxidation processes followed Langmuir–Hinshelwood (L–H) kinetics (Equation (22)) [30].

$$r_0 = \frac{k_{L-H} \times K \times C_0}{1 + k_{L-H} \times C_0} \quad (22)$$

The kinetics of As(III) oxidation in the Fe(III)-CaSO₃ system was studied by the initial rate method. The initial rate $r_0$ was taken as the average value of the change of As(III) concentration over the initial period. The initial oxidation rate of As(III) increased with its initial concentration (Figure 4). When the initial As(III) concentration is higher, the As(III) oxidation rate continues to increase. The relationship between $r_0$ and $C_0$ for As(III) oxidation followed the Langmuir–Hinshelwood (L–H) equation of heterogeneous reaction kinetics with a low adsorption constant (K) of 0.07 μM⁻¹ (Table 1). Therefore, $K \times C_0$ in the denominator can be ignored in the realm of low concentrations. The L-H equation thus becomes a simple pseudo-first-order linear kinetic equation ($r_0 = k_{L-H} \times K \times C_0 = 0.3 C_0$).
µM min⁻¹), which indicates the involvement of a solid-phase interface reaction mechanism in the oxidation of As(III) in the Fe(III)-CaSO₃ system.

2.4. Effect of the Initial Concentration of As(III) on its Oxidation

As(III) oxidation processes followed Langmuir–Hinshelwood (L–H) kinetics (Equation (22) [30].

\[
\begin{align*}
    r_0 &= K_{\text{L-H}} \times K \times C_0 \\
    &= \frac{0.3282c}{[1+0.07382c]} \\
    &= 0.3282c
\end{align*}
\]

The kinetics of As(III) oxidation in the Fe(III)-CaSO₃ system was studied by the initial rate method. The initial rate \( r_0 \) was taken as the average value of the change of As(III) concentration over the initial period. The initial oxidation rate of As(III) increased with its initial concentration (Figure 4). When the initial As(III) concentration is higher, the As(III) oxidation rate continues to increase. The relationship between \( r_0 \) and \( C_0 \) for As(III) oxidation followed the Langmuir–Hinshelwood (L-H) equation of heterogeneous reaction kinetics with a low adsorption constant (K) of 0.07 µM⁻¹ (Table 1). Therefore, K \( \times C_0 \) in the denominator can be ignored in the realm of low concentrations. The L-H equation thus becomes a simple pseudo-first-order linear kinetic equation (\( r_0 = k_{\text{L-H}} \times K \times C_0 = 0.3 \times C_0 \), µM min⁻¹), which indicates the involvement of a solid-phase interface reaction mechanism in the oxidation of As(III) in the Fe(III)-CaSO₃ system.

Figure 4. Effect of initial As(III) concentration on the Fe(III)-CaSO₃ system. Initial conditions: [Fe(III)] = 0.5 mM, [CaSO₃] = 30 mM, [As(III)] = 1–10 µM, pH 6.0, air bubbling at 0.5 L min⁻¹.

Table 1. Oxidation kinetics of As(III) according to the L-H equation in the Fe(III)-CaSO₃ system.

| \( C_0 \) (µM) | \( r_0 \) (µM min⁻¹) | Kinetic Equation | \( k_{\text{L-H}} \) | K (µM⁻¹) | \( R^2 \) |
|----------------|----------------------|-----------------|----------------|--------|--------|
| 1              | 0.1694               |                 |                 |        |        |
| 3              | 0.6731               |                 |                 |        |        |
| 5              | 1.3876               |                 |                 | 4.446  | 0.074  | 0.972  |
| 8              | 1.7167               | \( r_0 = \frac{0.3282c}{[1+0.07382c]} \) | 4.446  | 0.074  | 0.972  |
| 10             | 1.7896               |                 |                 |        |        |

\( C_0 \) is initial concentration (µM); \( r_0 \) initial rate (µM min⁻¹), \( k_{\text{L-H}} \) the rate constant (µM min⁻¹), and K the adsorption constant (µM⁻¹).

2.5. Contribution of Free Radicals to As(III) Oxidation

Several studies have shown that the generation of reactive oxygen species is the main reason for the oxidative degradation of pollutants in acidic environments [31,32]. The Fe(III)-CaSO₃ system involves oxysulfur free radicals, including SO₃²⁻, SO₅²⁻, and SO₄²⁻, formed according to Equations (1)–(8). HO• may be generated from SO₄²⁻, according to Equations (21) and (23), and may also contribute to the degradation of As(III). Quenching experiments were performed to better understand the reaction mechanisms (Figure 5). Ethanol (EtOH) and tert-butyl alcohol (TBA) were employed as radical scavengers.

\[
    \text{SO}_4^{2-} + \text{H}_2\text{O} \rightarrow \text{SO}_4^{2-} + \text{HO}^* + \text{H}^+
\]  

(23)
for less than 4 h before analysis. The concentrations of As(III) and As(V) in the filtrates were of analytical reagent grade or higher purity, and were used without further purification. Ethanol (EtOH) and tert-butyl alcohol (TBA) were used for radical quenching. All chemicals were of analytical reagent grade or higher purity, and were used without further purification.

3.2. Reaction Procedure

Figure 5. Contribution of free radicals in the Fe(III)-CaSO₃ system. Initial conditions: [Fe(III)] = 0.5 mM, [CaSO₃] = 30 mM, [As(III)] = 5 μM, [EtOH] = 5 mM, [TBA] = 2 mM, pH 6.0, air at 0.5 L min⁻¹.

EtOH has similar rate constants for SO₄⁻ and HO⁺ (kₓs) = (1.6–7.7) × 10⁷ M⁻¹ s⁻¹, kₓs = (1.6–7.7) × 10⁷ M⁻¹ s⁻¹ [33]. However, the rate constant for the reaction between TBA and HO⁺ (kₓs) = (3.8–7.6) × 10⁸ L mol⁻¹ s⁻¹) is 1000-times higher than that for the reaction between TBA and SO₄⁻ (kₓs = (4.0–9.1) × 10⁹ L mol⁻¹ s⁻¹) [34]. Hence, SO₄⁻ and HO⁺ contributions for As(III) oxidation can be distinguished by adding EtOH and TBA, respectively. After adding EtOH (5 mM), it was found that the oxidation rate of As(III) decreased from 0.4 to 0.07 min⁻¹, implying that this main reactive species generated by Fe(III)-CaSO₃ process were attributable to SO₄⁻ and HO⁺, the residual should be caused by SO₃⁻, as SO₃⁻ possesses so weak oxidative ability that cannot oxidize As(III) and SO₃⁻ tends to be rapidly oxidized to SO₄⁻ in the oxygen-containing condition [28]. Therefore, we surmised that SO₃⁻ caused the 17.5% As(III) oxidation. Moreover, when adding TBA (2 mM) into the solution, the oxidative rate decreased to 0.13 min⁻¹, showing that HO⁺ was responsible for about 67.5% of the As(III) oxidation. In conclusion, the reactive species mainly responsible in the Fe(III)-CaSO₃ system involved SO₄⁻, HO⁺ and SO₃⁻ generation that accounted for 15%, 67.5% and 17.5% contribution for As(III) oxidation, respectively.

3. Materials and Methods

3.1. Materials

NaAsO₂ (99.5%; Gracia Chemical Technology Co., Ltd., Chengdu, China) was dried in a desiccator for 24 h prior to use. Na₂HAsO₄·7H₂O was purchased from Alfa Aesar (A Johnson Matthey Co., Ltd., Shanghai, China). CaSO₃ was purchased from Shanghai Aladdin Bio-Chef Technology Co., Ltd. (Shanghai, China). Fe₂(SO₄)₃, NaOH, H₂SO₄, KBH₄ and HCl were purchased from Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China). Ethanol (EtOH) and tert-butyl alcohol (TBA) were used for radical quenching. All chemicals were of analytical reagent grade or higher purity, and were used without further purification.
3.2. Reaction Procedure

All experiments were performed in a 250 mL cylindrical reactor cooled by external jacket water circulation at a constant temperature of 25 °C (Figure 6). A 250 mL solution containing As(III) at the desired concentration was placed in the reactor and constantly stirred with a polytetrafluoroethylene-coated magnetic stirrer. Sulfite consumed oxygen quickly in aqueous solution, so hence synthetic air was constantly pumped into the reaction solution. Then, Fe(III) and CaSO₃ solutions were added, and the pH was quickly re-adjusted to the desired value (± 0.1). Aliquots (4.5 mL) were withdrawn at specific time intervals and immediately mixed with 0.5 mL portions of 6 M HCl. The resultant mixtures were filtered through a 0.22 µm filter and preserved in the dark at low temperature (4 °C) for less than 4 h before analysis. The concentrations of As(III) and As(V) in the filtrates were determined by HPLC-HG-AFS.

3.3. Analysis

The sample was acidified and filtered in advance, so that the adsorbed As in the reaction solution has basically transformed it into dissociative state. Arsenic concentration was determined by using liquid-phase hydride-generation–atomic fluorescence spectrometry (LC-HG-AFS). As(III) and As(V) in the reaction solution were separated on an ion chromatography column (PRP-X100, Hamilton, Switzerland) by eluting with a phosphate mobile phase (45 mM, pH 5.6). The concentrations of As(III) and As(V) were determined using 5% HCl–2% KBH₄ solution in HG-AFS [29].

4. Conclusions

The Fe(III)-CaSO₃ system can generate free radicals and effectively degrade As(III). It has been demonstrated that hydroxyl and oxysulfur radicals are the active species in the mechanism of As(III) oxidation. Under conditions of pH 6.0, the optimal concentrations of Fe(III) and CaSO₃ in the Fe(III)-CaSO₃ system are 0.5 and 30 mM, respectively, whereupon the As(III) oxidation efficiency can reach 72.1% after 1 h. Radical scavenging tests have
indicated that oxidation of As(III) is caused by HO• (67.5%), SO₃²⁻ (17.5%) and SO₄²⁻ (15%). The results presented here imply that in the Fe(III)-CaSO₄ system, replacing soluble sulfites with slightly soluble sulfites is an effective strategy in oxidizing As(III) to As(V), and in the Fe(III)-CaSO₄ system, replacing soluble sulfites with slightly soluble sulfites is an effective in degrading arsenic, and the Fe(III)-CaSO₄ system offers a cost-effective process for arsenic removal from contaminated waters, and that sulfite holds significant promise as a new resource utilization method of desulfurized gypsum.

Author Contributions: M.C., and S.Q. performed the As(III) oxidation experiments; F.W. and G.M. conceived and designed the experiments; J.L. and S.Q. analyzed the data; M.C. and S.Q. participated in drafting the article; all authors revised the article. All authors have read and agreed to the published version of the manuscript.
