Summary

Background. Early menopause is a risk factor for several health-related problems of women. No single study was available in literature to determine the associated factors for early menopause in Bangladesh.

Objectives. The aim of this study was to determine the prevalence and factors associated with early menopause in Bangladesh.

Material and methods. Data was extracted from the nationally representative Bangladesh Demographic and Health Survey (BDHS) 2014. This data was collected from 17,863 married Bangladeshi women throughout the entire country using two-stage stratified cluster sampling. The BDHS 2014 report showed that women aged 30–49 years are estimated to be menopausal. Considering this estimation, we excluded women whose age was less than 30 years. Women whose menstrual periods had stopped because of pregnancy and postpartum amenorrhea, as well as those with some incomplete information and missing samples, were excluded from data. Consequently, 8,885 women were considered for this study. The chi-square test was used for bivariate analysis, and logistic regression was used as multivariate analysis.

Results. The prevalence of early menopause in Bangladesh was 10.80%. The binary multivariate logistic regression model demonstrated that women with no education were more likely to experience early menopause compared to women of higher education (AOR = 3.39, 95% CI: 2.22–5.20, p < 0.001). A lower rate of early menopause was especially found among women who were living in the Sylhet division that were currently married and currently using contraceptive methods.

Conclusions. The stepwise binary logistic regression model exhibited that most of the significant predictors were modifiable factors for early menopause. Authorities should provide basic education on early menopause to less educated women.

Keywords: logistic models, Bangladesh, chi-square distribution, menopause.

Over the last two decades, plenty of research has been carried out on menopause, and the various risk factors for early menopause have been investigated. The results were inconsistent, but the trend of the results suggested that women with no education experienced earlier menopause than women with higher education [15, 16]. Several internal studies found a lower BMI to be associated with the onset of early menopause [7, 17, 18]. However, another study showed that BMI was not significantly associated with menopause [19]. A study in India reported a higher prevalence and earlier onset of menopause by multiple parity [20], although a number of international studies showed a high prevalence of earlier menopause in nulliparous women [21, 22]. Women with a lower socio-economic status had earlier menopause [16, 23–26]. Marital status, contraceptive use status and smoking status were significantly associated with early menopause [7, 19, 27].

Bangladesh is a developing country in Southeast Asia. In Bangladesh, most of the women are uneducated and have no consciousness about menopause [10]. Now-a-days, studies on menopause have received much attention, due to the increased life expectancy of women [28]. In Bangladesh, only three research studies based on a regional survey have been carried out concerning menopause [4, 10, 29]. These studies were conducted on a small population in Bangladesh to identify menopausal age and assess the symptoms for early and late menopause, but these were all restricted to a specific region. Among these, another study also investigated the effect of early menopause and late menopause on quality of life and found that menopausal...
symptoms were strongly associated with quality of life for both early and late menopausal women. It was also noted that early menopausal women had to face more problem of menopausal symptoms compared to late menopausal women in Bangladesh [4]. To our knowledge, there has been no single study to determine associated factors with early menopause in Bangladesh.

Objectives

The main objective of this study was to determine the prevalence and associated factors of early menopause.

Material and methods

Data was extracted from the nationally representative Bangladesh Demographic and Health Survey (BDHS) conducted in 2014. This survey was authorised by the National Institute of Population Research and Training (NIPORT) of the Ministry of Health and Family Welfare. Data was collected using two-stage stratified random sampling from 17,863 ever married women. The BDHS report showed that women between the age of 30–49 are estimated to be menopausal. Considering this estimation, we excluded women whose age was less than 30 years from the data. We also exclude women whose menstrual periods had stopped because of pregnancy and postpartum amenorrhea, as well as those with some incomplete information and missing samples. Consequently, 8,885 women were considered for this study.

Outcome variable

Menopause is a time that marks the end of women’s menstrual cycles. A woman is diagnosed as menopausal after she has gone 12 months without a menstrual period. Menopausal experience decreases according to the increases of age. The prevalence of menopause among Bangladeshi women was 21.90%, where early menopause was 10.80%. Socio-demographic characteristics and the prevalence of early menopause are presented in Table 1. The chi-square test revealed that some independent variables were significantly associated with early menopause. Those variables that are found significant are considered as independent variables for logistic regression analysis. Table 1 represents the effect of selected factors on the early menopausal status of Bangladeshi women. The results of the multivariate binary logistic regression model showed that women who lived in the Sylhet division were less likely to experience early menopause, followed by Barisal [AOR = 1.51, 95% CI: 1.14–2.00, p < 0.05] and Rajshahi [AOR = 1.34, 95% CI: 1.01–1.79, p < 0.05] and Rangpur [AOR = 1.51, 95% CI: 1.14–2.00, p < 0.05]. Women with no education were more likely to experience early menopause [AOR = 3.39, 95% CI: 2.22–5.20, p < 0.001] than women with higher education. It was found that the risk of women to experience early menopause decreases according to the increases their education level. The current marital status of women was found as a significant [AOR = 1.53, 95% CI: 1.22–1.91, p < 0.001] predictor for early menopause. Women who were not using any contraceptive method had a 3.62-times [AOR = 3.62, 95% CI: 3.12–4.20, p < 0.001] higher chance of early menopause than who were using a contraceptive method (Table 1).

Ethical approval

Data was collected from the Bangladesh Demographic and Health Survey (BDHS) 2014. This study was approved by the Ministry of Health and Family Welfare, Government of Bangladesh.

Results

A total number of 8,885 women were analysed for this study, with a mean age of 38.60 ± 5.74 years (ranging from 30 to 49). The prevalence of menopause among Bangladeshi women was 21.90%, where early menopause was 10.80%. Socio-demographic characteristics and the prevalence of early menopause are presented in Table 1. The chi-square test revealed that some independent variables were significantly associated with early menopause. Those variables that are found significant are considered as independent variables for logistic regression analysis. Table 1 represents the effect of selected factors on the early menopausal status of Bangladeshi women. The results of the multivariate binary logistic regression model showed that women who lived in the Sylhet division were less likely to experience early menopause, followed by Barisal [AOR = 1.50, 95% CI: 1.11–2.02, p < 0.05], Dhaka [AOR = 1.15, 95% CI: 0.86–1.53, p < 0.05], Khulna [AOR = 1.98, 95% CI: 1.51–2.59, p < 0.001], Rajshahi [AOR = 1.34, 95% CI: 1.01–1.79, p < 0.05] and Rangpur [AOR = 1.51, 95% CI: 1.14–2.00, p < 0.05]. Women with no education were more likely to experience early menopause [AOR = 3.39, 95% CI: 2.22–5.20, p < 0.001] than women with higher education. It was found that the risk of women to experience early menopause decreases according to the increases their education level. The current marital status of women was found as a significant [AOR = 1.53, 95% CI: 1.22–1.91, p < 0.001] predictor for early menopause. Women who were not using any contraceptive method had a 3.62-times [AOR = 3.62, 95% CI: 3.12–4.20, p < 0.001] higher chance of early menopause than who were using a contraceptive method (Table 1).

| Region | POEM % | Unadjusted Model | Adjusted Model |

Table 1. Prevalence of early menopause (POEM) by background characteristics and the effect of selected variables on early menopause in women in Bangladesh.
that early menopause was a risk factor for several health problems, such as cardiovascular diseases, neurological diseases, diabetes, psychiatric diseases, osteoporosis, etc. [12–14, 33]. Although early menopause is a concerning issue for women’s health, there have been no menopausal studies to determine the high-risk factors of early menopause in Bangladesh. In this study, we found significant risk factors, such as regions, education level, current marital status and contraceptive use status, for early menopause in Bangladesh.

There are seven major administrative regions (divisions) in Bangladesh. In this study, the regional rate of early menopause among the women of the representative regions with the overall prevalence of early menopause in Bangladesh was also analysed. The prevalence of early menopause was found to be the highest in the Sylhet region, followed by the others. A previous study showed that the higher the number of pregnancies, the lower the risk of early menopause [34]. The BDHS 2014 report also revealed that the number of pregnancies was higher among Sylhet region women, since the total number of ever born children was highest in the Sylhet region [35], which we think could be an attributing factor for the lower early menopause rate in this region.

Education level has been found to be a major determining factor significantly associated with early menopause. Women with no education were more likely to have early menopause, and early menopause rates decreased among women with an increased education level. This finding is consistent with other studies [15, 16, 19, 26].

In this study, we found that a lower wealth index was significantly associated with early menopausal status from univariate analysis, and this finding is consistent with others studies [19, 36, 37]. The chance of early menopause decreased with respect to an increase in economic condition.

Current marital status is also an important predictor for early menopause. In our study, widowed/divorced/separated women were more likely to have early menopause than women who were married, which is dissimilar from the results of a former study conducted in the United States [38, 39]. This variation could be due to the differences in socio-cultural rituals.

Women who were not using any contraceptive method had a 3.62-times higher chance of early menopause than those who used contraceptive methods.

Among the selected variables considered in the study, religion, place of residence, current working status and BMI did not show a statistically significant relationship with early menopause. Research has shown that BMI is not a significant predictor for early menopause [19]. This is the first menopausal research based on national representative data in Bangladesh, it is the main strength of this study.

**Limitations of the study**

This study has a number of potential limitations. Since this is a cross-sectional study, it is difficult to establish a causal relationship between early menopause and selected factors, whereas a longitudinal study is more effective. Despite the above limitations, the findings of this study will contribute to understanding and identifying the associated factors of early menopause in Bangladesh.

**Conclusions**

Globally, early menopause is a concern for several health problems of women. The prevalence of early menopause was higher in Bangladesh. Our study showed that regions, education level, current marital status and current contraceptive use status were significantly associated with early menopause. The government should take necessary steps to control early menopause.
