Abstract: The objective of this work is to present the existence result of for the non-steady compressible Navier-Stokes equations via time discretization. We consider the two-dimensional case with a slip boundary conditions. First, the existence of weak solution for a fixed length of time interval $\Delta t > 0$ is presented and then the limit passage as $\Delta t \to 0^+$ is carried out. The proof is based on a new technique established for the steady Navier-Stokes equations by Mucha P. and Pokorný M. 2006 Nonlinearity 19 1747-1768.

Keywords: Navier-Stokes equations, barotropic compressible viscous fluid, weak solution, time discretization

Mathematics Subject Classification: 76N10; 35Q30

1 Introduction

We investigate a system being time discretization of two dimensional Navier-Stokes equations in the isentropic regime

$$\frac{1}{\Delta t} \left( \rho^k v^k - \rho^{k-1} v^{k-1} \right) + \text{div}(\rho^k v^k \otimes v^k) - \mu \Delta v^k - (\mu + \nu) \nabla \text{div} v^k + \nabla \pi(\rho^k) = 0,$$

where $\Omega \subset \mathbb{R}^2$ is a fixed domain, $v^k : \Omega \to \mathbb{R}^2$- the velocity field, $\rho^k : \Omega \to \mathbb{R}^+_0$- the density, $\pi : \mathbb{R}^+_0 \to \mathbb{R}$- the internal pressure given by the constitutive equation

$$\pi(\rho^k) = (\rho^k)^\gamma, \quad \gamma > 2.$$

We assume that the walls of $\Omega$ are rigid and that the fluid slips at the boundary

$$v^k \cdot n = 0, \quad \text{at } \partial \Omega
$$

$$n \cdot T(v^k, \pi) \cdot \tau + f v^k \cdot \tau = 0 \quad \text{at } \partial \Omega,$$

(2)
where \( T(v^k, \pi) = 2\mu D(v^k) + (\nu \text{div} v - \pi)I \).

The conditions \((2)\) are known as the Navier or friction relations which means, that unlike in the case of complete slip of the fluid against the boundary, the friction effects, described by \( f \geq 0 \), may also be present. The customary zero Dirichlet condition may be understood as a special case of the above, when \( f \to \infty \).

We will always assume that our initial conditions \( \bar{\rho}_0, v_0 \) satisfy

\[
\bar{\rho}_0 \geq 0 \text{ a.e. in } \Omega, \quad \bar{\rho}_0 \in L_\gamma(\Omega),
\]

\[
v_0 \in L^{2/(\gamma+1)}(\Omega), \quad \bar{\rho}_0(v_0^2) \leq L_1(\Omega).
\]

The first main goal of this paper is to show that for \( \Delta t = \text{const.} \) the solutions of such a system exist in a sense of the following definition.

**Definition 1.** We say, the pair of functions \((\bar{\rho}^k, v^k) \in L_\gamma(\Omega) \times W^{1,p}(\Omega), v^k \cdot n = 0 \) at \( \partial \Omega \) is a weak solution to \((1)-(2)\) provided

\[
\int_\Omega \bar{\rho}^k v^k \cdot \nabla \varphi \, dx = \frac{1}{\Delta t} \int_\Omega (\bar{\rho}^k - \bar{\rho}^{k-1}) \varphi \, dx, \quad \forall \varphi \in C^\infty(\Omega),
\]

and

\[
\frac{1}{\Delta t} \int_\Omega (\bar{\rho}^k v^k - \bar{\rho}^{k-1} v^{k-1}) \varphi \, dx - \int_\Omega \bar{\rho}^k v^k \otimes v^k : \nabla \varphi \, dx + 2\mu \int_\Omega D(v^k) : D(\varphi) \, dx
\]

\[
+ \nu \int_\Omega \text{div} v^k \text{div} \varphi \, dx - \int_\Omega \pi(\bar{\rho}^k) \text{div} \varphi \, dx + \int_{\partial \Omega} f(v^k \cdot \tau)(\varphi \cdot \tau) \, dS = 0,
\]

\( \forall \varphi \in C^\infty(\Omega); \ \varphi \cdot n = 0 \) at \( \partial \Omega \).

The first main result reads as follows.

**Theorem 1.** Let \( \Omega \in C^2 \) be a bounded domain, \( \Delta t = \text{const.} \), \( \mu > 0 \), \( 2\mu + 3\nu > 0 \), \( \gamma > 2 \), \( f \geq 0 \), \( \bar{\rho}^{k-1} \geq 0 \). Then there exists a weak solution to \((1)-(2)\) such that

\( \bar{\rho}^k \in L_\infty(\Omega) \) and \( \bar{\rho}^k \geq 0 \),

\( v^k \in W^{1,p}(\Omega) \ \forall p < \infty \),

\( \int_\Omega \bar{\rho}^k \, dx = \int_\Omega \bar{\rho}^{k-1} \, dx \),

moreover \( \|\bar{\rho}^k\|_\infty \leq (\Delta t)^{3/(1-\gamma)} \).

The result we present here was already stated without requiring any assumption on the smallness of initial data f.i. in the monograph of Lions \([5]\) for the zero Dirichlet condition when \( \Omega \) is bounded and for the whole space. It was used there as a tool in analysing the steady and non-steady cases. The approach presented there or in other works based on the Feireisl idea \([5], [2], [4]\) benefit from the properties of the effective viscous flux. Our technique allows for essential reduction of the number of technical
tricks and enables to get the required $L_\infty$ regularity for the density directly at the level of approximate system.

The second result refers to a passage to the limit with length of time interval $\Delta t \to 0$. We will show that for such a case our solution tends to the weak solution of non-steady compressible Navier-Stokes system with a slip boundary condition:

\begin{align}
(qv)_t + \text{div}(qv \otimes v) - \mu \Delta v - (\mu + \nu) \nabla \text{div} v + \nabla \pi(q) = 0 & \quad \text{in} \quad \Omega \\
v \cdot n = 0 & \quad \text{at} \quad \partial \Omega \\
\nu \cdot T(v, \pi) \cdot \tau + f v \cdot \tau = 0 & \quad \text{at} \quad \partial \Omega,
\end{align}

(3)

in sense of the following definition.

**Definition 2.** We say, the pair of functions $(\varrho, v) \in L_\infty(L_\gamma) \times L_2(W^{1,2}_0)$, $v \cdot n = 0$ at $\partial \Omega$ is a weak solution to (3) provided

\begin{align*}
\int_0^T \int_\Omega (\varrho \varphi_t + \varrho v \cdot \nabla \varphi) \, dxdt = 0, & \quad \forall \varphi \in C_c^\infty([0, T) \times \overline{\Omega}),
\end{align*}

and

\begin{align*}
\int_0^T \int_\Omega (\varrho \varphi_t + \varrho v \otimes v \cdot \nabla x \varphi + \pi(q) \text{div}_x \varphi) \, dxdt = & \\
= \int_0^T \int_\Omega (2\mu \text{D}_x(v) : \text{D}_x(\varphi) + \nu \text{div}_x v \cdot \text{div}_x \varphi) \, dxdt + \int_0^T \int_{\partial \Omega} f (\varphi \cdot \tau)(\varphi \cdot \tau) \, dSdt, & \forall \varphi \in C_c^\infty([0, T) \times \overline{\Omega}); \quad \varphi \cdot n = 0 \text{ at } \partial \Omega.
\end{align*}

(4)

The existence of solutions to the non-steady system is provided by our second main result.

**Theorem 2.** Under the hypotheses of Theorem 1, the solution $(\varrho^k, v^k)$ converges to $(\varrho, v)$ as $\Delta t \to 0^+$ weakly (weakly$^*$) in $L_\infty(L_\gamma) \times L_2(W^{1,2}_0)$. Moreover $\varrho$ belongs to $L_{\gamma+1}(\Omega \times (0, T))$ and the following energy inequality is satisfied for almost all $t \in [0, T]$

\begin{align*}
\int_\Omega \varrho^2(T)dx + \frac{1}{\gamma - 1} \int_\Omega \varrho^\gamma(T)dx + \int_0^T \int_\Omega (2\mu |D(v)|^2 + \nu (\text{div} v)^2) \, dxdt \\
+ \int_0^T \int_{\partial \Omega} f (v \cdot \tau)^2dx \, dt \leq C(\varrho^0, v^0).
\end{align*}
In the following section we will show the existence and uniqueness of regular solution to the problem being the new $\epsilon-$approximation scheme for the time-discretized Navier-Stokes equations. Although the proof is based on the standard fixed-point method, we will precisely present most of steps in view of the fact that our approximation affects the nonlinear term too. Our solution $(\rho^k, v^k)$ will be obtained as a weak limit as $\epsilon \to 0^+$ of the sequences $(\rho^k_\epsilon, v^k_\epsilon)$. This limit process will be carried out in Section 3 by using some uniform estimates and the following property of the density sequence 

$$\lim_{\epsilon \to 0^+} \left| \{ x \in \Omega : \rho^k_\epsilon(x) > m \} \right| = 0$$

for $m$ sufficiently large, which enables to show the convergence of the pressure.

2 Approximation

In this section we present a scheme of approximation being a modification of the one introduced by Mucha Pokorny [6] for the steady case. It is needed to investigate the issue of existence of solutions in the case when the time step $(\Delta t)$ is constant and while disposing a sufficient information for the density and velocity at the $k-1$ moment of time. Although for further purposes there is a necessity to keep trace of the dependence on these quantities in almost all estimates.

Let 

$$h = \rho^{k-1}, \quad g = \rho^k, \quad v = v^k, \quad g = v^{k-1}. \tag{5}$$

The objective of this part of work will be then to examine the following approximative system:

$$\begin{align*}
\alpha (g - hK(g)) + \text{div}(K(g)gv) - \epsilon \Delta g &= 0 \\
\alpha (g v - hg) + \text{div}(K(g)gv \otimes v) - \mu \Delta v - (\mu + \nu) \nabla \text{div}v + \nabla P(g) + \epsilon \nabla g \nabla v &= 0 \\
\frac{\partial \rho}{\partial n} &= 0 \quad \text{at} \quad \partial \Omega, \\
v \cdot n = 0 &= 0 \quad \text{at} \quad \partial \Omega, \\
n \cdot T(v, P(g)) \cdot \tau + f v \cdot \tau &= 0 \quad \text{at} \quad \partial \Omega, 
\end{align*} \tag{6}$$

we will write simply $\rho, v$ insted of $\rho_\epsilon, v_\epsilon$ when no confusion can arise. The other denotations are the following:

$$P(\rho) = \gamma \int_0^\rho s^{\gamma-1} K(s) ds,$$

where

$$K(\rho) = \begin{cases} 
1 & \rho \leq m_1, \\
0 & \rho \geq m_2, \\
\in (0, 1) & \rho \in (m_1, m_2),
\end{cases}$$

and

$$K(\cdot) \in C^1(\mathbb{R}) \quad K'(\rho) < 0 \text{ in } (m_1, m_2),$$

for some constants $m_1, m_2$. To avoid the difficulties conected with the case when $m_1 \to m_2$ we set the difference $m_2 - m_1$ to be constant, equal 1.

The existence of a regular solution is guaranteed by the theorem.
Theorem 3. Let $\Omega \in C^2$, $\epsilon, \phi_0, \frac{1}{\frac{\partial}{\partial n}} > 0$. Then there exist a regular solution $(\rho, v)$ to (6), $\rho \in W^2_p(\Omega)$, $v \in W^2_p(\Omega)$ for all $p < \infty$.

Moreover

\begin{align*}
0 \leq \rho \leq m_2 \quad & \text{in } \Omega, \\
\int_{\Omega} \rho \, dx \leq \int_{\Omega} h \, dx. 
\end{align*}

Proof. We assume, that $\rho, v$ are regular solutions to (6) and prove some estimates first, after we go on with the existence.

Step 1. Proof of (8).

Integrating the first equation of (6) over $\Omega$ one gets

\[ \alpha \int_{\Omega} (\rho - hK(\rho)) \, dx + \int_{\partial \Omega} K(\rho)v \cdot ndS - \epsilon \int_{\partial \Omega} \frac{\partial \rho}{\partial n} \, dS = 0, \]

the boundary integrals vanish and due to the definition of $K(\cdot)$ we truly have

\[ \int_{\Omega} \rho \, dx = \int_{\Omega} K(\rho)h \, dx \leq \int_{\Omega} h \, dx. \]

Step 2. Non-negativity of $\rho$.

Assume, that we have $h \geq 0$ in $\Omega$, the proof follows by the induction. We integrate first equation of (6) over $\Omega^- = \{x \in \Omega : \rho(x) < 0\}$

\[ \alpha \int_{\Omega^-} (\rho - K(\rho)h) \, dx + \int_{\partial \Omega^-} K(\rho)v \cdot ndS - \epsilon \int_{\partial \Omega^-} \frac{\partial \rho}{\partial n} \, dS = 0, \]

the first boundary integral vanishes since either $\rho$ or $v \cdot n$ equals 0 at $\partial \Omega^-$. Moreover, we know that $\frac{\partial \rho}{\partial n} \geq 0$ at $\partial \Omega^-$, hence

\[ \int_{\Omega^-} \rho \, dx \geq \int_{\Omega^-} K(\rho)h \, dx \geq 0, \]

but this leads to conclusion that $|\Omega^-| = 0$ and consequently $\rho \geq 0$ in $\Omega$.

Step 3. Upper bound for $\rho$.

Assume that $h \leq m_2$. This time we integrate the approximate continuity equation over $\Omega^+ = \{x \in \Omega : \rho(x) \geq m_2\}$

\[ \alpha \int_{\Omega^+} (\rho - K(\rho)h) \, dx + \int_{\partial \Omega^+} K(\rho)v \cdot ndS - \epsilon \int_{\partial \Omega^+} \frac{\partial \rho}{\partial n} \, dS = 0, \]

At $\partial \Omega^+$ we have $\frac{\partial \rho}{\partial n} \leq 0$ and either $K(\rho)$ or $v \cdot n$ equals 0. Thus, in the similar way as previously, the observation

\[ \int_{\Omega^+} \rho \, dx \leq m_2 \int_{\Omega^+} K(\rho) \, dx \leq 0 \]
implies that \( q \leq m_2 \) in \( \Omega \).

Step 4. Existence.

In accordance with our denotations the proof of existence of approximate solutions is almost identical to the one presented in [6]. In the first step we define for \( p \in [1, \infty] \):

\[
M_p = \{ w \in W^1_p(\Omega); w \cdot n = 0 \text{ at } \partial \Omega \}.
\]

and we claim that the following proposition, which is the analogue of Proposition 3.1.

**Proposition 4.** Let assumptions of theorem 3 be satisfied. Then the operator \( S : M_\infty \to W^2_p(\Omega) \), where

\[
S(v) = q,
\]

\[
\alpha q + \text{div}(K(q)qv) - \epsilon \Delta q = \alpha hK(q) \quad \text{in} \quad \Omega
\]

\[
\frac{\partial q}{\partial n} = 0 \quad \text{at} \quad \partial \Omega
\]

is well defined for any \( p < \infty \). Moreover

- \( q = S(v) \) satisfy
  \[
  \int_\Omega qdx \leq \int_\Omega hdx.
  \]
- If \( h \geq 0 \) then \( q \geq 0 \) a.e. in \( \Omega \).
- If \( \|v\|_{1,\infty} \leq L, \quad L > 0 \) then
  \[
  \|q\|_{2,p} \leq C(\epsilon, p, \Omega)(1 + L)\|h\|_p, \quad 1 < p < \infty.
  \] (9)

The only difference in the formulation and the proof relates to the fact that \( h \) is not a constant parameter any more and that there appears \( g \) instead of \( v \). But the assumption that the regular solution in \( k-1 \) moment of time exist allows to replace the modulus by the \( L_p \) norm of \( h \).

In the next step of proof of Theorem 3 we will consider the Lame operator \( \mathcal{T} : M_\infty \to M_\infty \)

defined as follows: \( w = \mathcal{T}(v) \) is a solution to the problem

\[
-\mu \Delta w - (\mu + \nu) \nabla \text{div} w = \alpha hg - \alpha g v - \text{div}(K(g)qv \otimes v) - \nabla P(g) - \epsilon \nabla q \nabla v = F(g, v, h, g)
\]

\[
w \cdot n = 0 \quad \text{at} \quad \partial \Omega,
\]

\[
(n \cdot (2\mu D(w) + \nu \text{div} w I)) \cdot \tau + f v \cdot \tau = 0 \quad \text{at} \quad \partial \Omega
\]

Employing the Larey-Schauder fixed point theorem for the operator \( \mathcal{T} \) we can almost rewrite the proof of analogous fact [8] or [6]. The only part that that deserves more
careful study is the energy estimate. This in turn together with some information about the pressure $P(\varrho)$ will enable to pass to the limit with the length of time interval $\Delta t$. First observe that $(10)_1$ with $w = v$ and $\varrho = S(v)$ holds with a solution itself as a test function, therefore

$$
\alpha \int \Omega \varrho v^2 + \int \Omega \text{div}(K(\varrho)v \otimes v)v - \mu \int (\Delta v)v - (\mu + \nu) \int \Omega (\nabla \text{div}v) + \int \nabla P(\varrho)v + \epsilon \int \nabla \varrho \nabla vv = \alpha \int \Omega hgv.
$$

Next, integrating by parts and using condition on the boundary

$$
\alpha \int \Omega \varrho v^2 + \frac{1}{2} \int \Omega \text{div}(K(\varrho)v)\varrho v^2 + 2\mu \int \Omega |D(v)|^2 + \nu \int \Omega \text{div}^2v + \int \partial \Omega f(v \cdot \tau)^2 - \frac{\gamma}{\gamma - 1} \int \Omega \text{div}(K(\varrho)v)\varrho^{\gamma - 1} - \frac{\epsilon}{2} \int \Delta \varrho v^2 = \alpha \int \Omega hgv,
$$

including the information contained in $(10)_1$ one gets

$$
\frac{1}{2} \alpha \int \Omega (\varrho + K(\varrho)h)v^2 + 2\mu \int \Omega |D(v)|^2 + \nu \int \Omega \text{div}^2v + \int \partial \Omega f(v \cdot \tau)^2 + \gamma \alpha \int \Omega \varrho^\gamma - \frac{\gamma}{\gamma - 1} \alpha \int \Omega \varrho^{\gamma - 1}K(\varrho)h + \gamma \epsilon \int \Omega |\nabla \varrho|^{2\gamma} = \alpha \int \Omega hgv,
$$

now we add end substract $\frac{1}{2} \alpha \int \Omega h g^2$

$$
\frac{1}{2} \alpha \int \Omega (\varrho v^2 - h g^2) + \frac{1}{2} \alpha \int \Omega h |v - g|^2 + 2\mu \int \Omega |D(v)|^2 + \nu \int \Omega \text{div}^2v + \int \partial \Omega f(v \cdot \tau)^2 + \gamma \alpha \int \Omega \varrho^\gamma - \frac{\gamma}{\gamma - 1} \alpha \int \Omega \varrho^{\gamma - 1}K(\varrho)h + \gamma \epsilon \int \Omega |\nabla \varrho|^{2\gamma} \leq 0, \quad (11)
$$

next we add and substract $\frac{1}{\gamma - 1} \alpha \int \Omega h^\gamma$

$$
\frac{1}{2} \alpha \int \Omega (\varrho v^2 - h g^2) + \frac{1}{2} \alpha \int \Omega h |v - g|^2 + 2\mu \int \Omega |D(v)|^2 + \nu \int \Omega \text{div}^2v + \int \partial \Omega f(v \cdot \tau)^2 + \frac{1}{\gamma - 1} \alpha \int \Omega (\varrho^\gamma - h^\gamma) + \gamma \alpha \int \Omega ((\gamma - 1)\varrho^\gamma + h^\gamma - \gamma \varrho^{\gamma - 1}K(\varrho)h) + \gamma \epsilon \int \Omega |\nabla \varrho|^{2\gamma} \leq 0.
$$

Note, that since $\varrho, h \geq 0$ and $K(\varrho) \leq 1$ we have that $(\gamma - 1)\varrho^\gamma + h^\gamma - \gamma \varrho^{\gamma - 1}K(\varrho)h \geq 0$. Referring to our oryginal denotation we may now sum $(12)$ from $k = 1$ to $k = n$ and
obtain the following bounds:
\[
\sup_{0 \leq n \leq M} \frac{1}{\gamma - 1} \alpha \| e^n \|_{\gamma} + \frac{1}{2} \alpha \| e^n(v^n)^2 \|_1 \leq \frac{1}{\gamma - 1} \alpha \| e^0 \|_{\gamma} + \frac{1}{2} \alpha \| e^0(v^0)^2 \|_1,
\]
thus
\[
\sup_{0 \leq n \leq M} \| e^n \|_{\gamma} + \| e^n(v^n)^2 \|_1 \leq C(e^0, v^0, \gamma, \Omega),
\] (13)
in particular C is independent of \( k, \epsilon \) and \( \alpha \), moreover
\[
\sum_{k=1}^{M} \int_{\Omega} \left[ (\varrho_k - 1)|v_k - v^{k-1}|^2 + (\gamma - 1)(\varrho_k)^{\gamma} + (\varrho^{k-1})^{\gamma} - \gamma(\varrho^{k-1})^{\gamma-1}K(\varrho^k)\varrho^{k-1} \right] \leq C
\] (14)
with the same constant \( C \). The information contained here turns out to be one of the crucial importance at the second stage of this work while showing that the passage with \( \Delta t \to 0 \) gives the solution to the evolutionary case. Namely, since for \( \gamma > 2 \) there exists a positive constant \( \delta \), such that
\[
(\gamma - 1)(\varrho^{k})^{\gamma} + (\varrho^{k-1})^{\gamma} - \gamma(\varrho^{k})^{\gamma-1}K(\varrho^k)\varrho^{k-1} \geq \delta |\varrho^k - \varrho^{k-1}|^\gamma,
\]
hence (14) ensures
\[
\sum_{k=1}^{M} |\varrho^k - \varrho^{k-1}|^\gamma \leq C.
\] (15)

Additionally we have
\[
\sum_{k=1}^{M} \| Dv^k \|_2^2 \leq \alpha C
\]
and by Korn’s inequality
\[
\sum_{k=1}^{M} \| v^k \|_{1,2}^2 \leq \alpha C
\] (16)
here the constant \( C \) depends also on \( \mu \) and \( \nu \).
Finally we also get
\[
\sum_{k=1}^{M} \| \nabla (\varrho^k) \|^2 \leq \frac{\alpha}{\epsilon} C.
\] (17)

This information allows us to repeat the procedure described in [8], which together with the Proposition [3] yield the existence of regular solutions, and hence the proof of Theorem [3] is complete.
Apart from the information resulting from the first a priori estimate, the limit passage requires also some estimates independent \( \epsilon, \alpha \) and \( m_2 \).
First of them is the estimate for the norm of gradient of the density. Observe that
multiplying \( \epsilon_1 \) by \( \varrho \) and integrating over \( \Omega \) one get

\[
\epsilon \int_\Omega |\nabla \varrho|^2 = \alpha \int_\Omega hK(\varrho)\varrho - \alpha \int_\Omega \varrho^2 - \int_\Omega K(\varrho)\varrho \cdot \nabla \varrho
\]

\[
\leq \alpha Cm_2 + \int_\Omega v \cdot \nabla \left( \int_0^\varrho K(t) dt \right) = \alpha Cm_2 - \int_\Omega \text{div} \left( \int_0^\varrho K(t) dt \right)
\]

\[
\leq \alpha Cm_2 + \int_\Omega |\text{div}v|^2 \leq \alpha Cm_2 + \sqrt{\alpha Cm_2^2}.
\]

This means that \( \|\nabla \varrho\|_2 \) may blow up as \( \epsilon \to 0^+ \), however we can provide that \( \epsilon\|\nabla \varrho\|_2 \) will tend to zero, i.e.

\[
\epsilon\|\nabla \varrho\|_2 \leq \sqrt{\epsilon}C(\alpha, m_2), \quad \text{(18)}
\]

for some constant \( C \) independent of \( \epsilon \).

Now we would like obtain integrability of the pressure with the power 2, as previously independently of \( \epsilon \) and, if possible, of \( m_2 \).

Therefore the choice of an appropriate test function seems to be obvious:

\[
\Phi = B(P(\varrho) - \{P(\varrho)\}), \quad \text{in } \Omega
\]

\[
\Phi = 0 \quad \text{at } \partial \Omega
\]

where \( B \) is the Bogovskii operator. By Lemma 3.17 from [8] and the Poincare inequality we have:

\[
\|\Phi\|_p \leq c(p, \Omega)\|P(\varrho)\|_p, \quad \|\nabla \Phi\|_p \leq c(p, \Omega)\|P(\varrho)\|_p
\]

\[
0 < p < \infty, \quad \bar{p} = \begin{cases} 
2p \quad \text{if } p < 2 \\
\frac{2p}{2-p} \quad \text{arbitrary} \quad \geq 1 \quad \text{if } p = 2 \\
\infty \quad \text{if } p > 2.
\end{cases}
\]

From this testing, the following identity appears:

\[
\int_\Omega P(\varrho)^2 = \frac{1}{|\Omega|} \left( \int_\Omega P(\varrho) \right)^2 + \alpha \int_\Omega (\varrho v - h\varrho)\Phi + \mu \int_\Omega \nabla v \cdot \nabla \Phi + (\mu + \nu) \int_\Omega \text{div}v \text{div}\Phi
\]

\[
- \int_\Omega K(\varrho)\varrho v \cdot \nabla \Phi + \epsilon \int_\Omega \nabla \varrho \nabla v \Phi = \sum_{i=1}^6 I_i.
\]

Now each term will be estimated separately.

(i) By the estimate \( \|\| \) and the definition of \( P \) the first one comes straightforward

\[
I_1 = \frac{1}{|\Omega|} \left( \int_\Omega P(\varrho) \right)^2 \leq \frac{1}{|\Omega|} \left( \int_\Omega \varrho^2 \right)^2 \leq C.
\]
(ii) The relation (19) together with the estimate (13) imply
\[ I_2 = \alpha \int_\Omega (gv - hg) \Phi \, dx \leq C\alpha \left( \|\varrho\|^{1/2}_\gamma \|gv^2\|^{1/2}_1 + \|h\|^{1/2}_\gamma \|hg^2\|^{1/2}_1 \right) \|P(\varrho)\|_2 \leq C\alpha \|P(\varrho)\|_2. \]

(iii) We also have \( \|\nabla \Phi\|_2 \leq \|\varrho\|_2 \), thus
\[ I_3 + I_4 = \mu \int_\Omega \nabla v \nabla \Phi + (\mu + \nu) \int_\Omega \text{div} v \text{div} \Phi \leq C\|v\|_2 \|P(\varrho)\|_2 \leq C\alpha^{1/2} \|P(\varrho)\|_2. \]

(iv) Since the modulus of \( K \) is less than 1, the Hölder’s inequality and imbedding mentioned above lead to
\[ I_5 = \int_\Omega K(\varrho)gv \otimes v : \nabla \Phi \leq C\|\varrho\|_\gamma \|v\|_{1,2}^2 \|P(\varrho)\|_2 \leq C\alpha \|P(\varrho)\|_2. \]

(v) Finally, employing the Hölder’s inequality we may get that
\[ I_6 = \epsilon \int_\Omega \nabla \varrho \nabla v \Phi \leq \epsilon \|\nabla \varrho\|_q \|v\|_{1,2} \|P(\varrho)\|_2, \]
for some \( q > 2 \). To get the estimate for \( \|\nabla \varrho\|_q \) we need to interpret the approximate continuity equation as a Neumann-boundary problem
\[ -\epsilon \Delta \varrho = \text{div} b \quad \text{in } \Omega \]
\[ \frac{\partial \varrho}{\partial n} = b \cdot n \quad \text{at } \partial \Omega, \tag{20} \]
with the right hand side
\[ b = \alpha \mathcal{B}(K(\varrho)h - \varrho) - K(\varrho)gv. \]

From the classical theory we know that if \( \partial \Omega \) is smooth enough and if \( b \in (L_p(\Omega))^2 \), then there exists the unique \( \varrho \in W^{1}_p(\Omega) \) satisfying (20) in the weak sence, such that \( \int_\Omega \varrho \, dx = \text{const} \). Moreover
\[ \|\nabla \varrho\|_p \leq \frac{c(p, \Omega)}{\epsilon} \|b\|_p. \tag{21} \]
Now, in our case assume that \( \gamma > q > 2 \) then the \( q \)-norm of \( b \) may be estimated as
\[ \|b\|_q \leq \alpha(\|\varrho\|_q + \|h\|_q) + C\|\varrho\|_\gamma \|v\|_{1,2} \leq C_1 \alpha + C_2 \sqrt{\alpha}, \tag{22} \]
thus the observation (21) yields the following
\[ I_6 = \epsilon \int_\Omega \nabla \varrho \nabla v \Phi \leq (C_1 \alpha^{3/2} + C_2 \alpha) \|P(\varrho)\|_2. \]
Gathering the estimates terms \( I_i \) for \( i = 1, \ldots, 6 \) one can easily see that
\[
\|P(q)\|_2 \leq C\alpha^{3/2},
\] (23)
where the constant \( C \) does not depend on \( \epsilon \) nor \( m_2 \).

Now our aim will be to estimate the norm of \( \nabla v \) in \( L_q(\Omega) \) for \( q \geq 2 \). For this purpose we will apply to the system (10) the following Lemma (for the proof, see [6] Lemma 3.3.).

**Lemma 5.** Let \( 1 < p < \infty, \ \Omega \in C^2, \ F \in (M_{2p/(p+2)})^*, \ \mu > 0, 2\mu + 3\nu > 0. \) Then there exists the unique \( w \in M_p \), solution to (17). Moreover
\[
\|w\|_{1,p} \leq C(p, \Omega)\|F\|_{(M_{p/(p-1)})^*}.
\]
If \( \Omega \in C^{l+2}, \ F \in W^l_p(\Omega), \ l = 0, 1, \ldots \) then \( w \in W^{l+1}_p(\Omega) \) and
\[
\|w\|_{l+2,p} \leq C(p, \Omega)\|F\|_{l,p}.
\]

If we consider the approximate momentum equation as a part of Lame system with \( w = v \) we will get the estimate for the norm of \( \nabla v \) in \( L_q(\Omega) \)
\[
\|\nabla v\|_q \leq C(\alpha\|qv\|_{2q/(q+2)} + \alpha\|hg\|_{2q/(q+2)}) + \|K(q)v \otimes v\|_q + \|P(q)\|_q + \epsilon\|\nabla q\nabla v\|_{2q/(q+2)}).
\]
Recalling \( \gamma > 2 \), by (13) and by (16) one gets
\[
\alpha\|qv\|_{2q/(q+2)} + \alpha\|hg\|_{2q/(q+2)} \leq C\alpha(\|qv\|_2 + \|hg\|_2) \leq C\alpha^{3/2}.
\]
By the definition of \( P \) and the Hölder’s inequality we also have
\[
\|K(q)v \otimes v\|_q \leq C\|P(q)\|_{\gamma/\gamma} \|v\|_q \|v\|_2 \leq C\alpha\|P(q)\|_{q/\gamma}^{1/\gamma}.
\]
At this step there is a need to include the estimates depending on the parameter \( m_2 \), more precisely we will use
\[
\|P(q)\|_q \leq \|P(q)\|_{\infty}^{1-2/q}\|P(q)\|_2^{2/q} \leq C\alpha^{3/q}m_2^{(1-2/q)\gamma},
\]
\[
\epsilon\|\nabla q\nabla v\|_{2q/(q+2)} \leq \epsilon\|\nabla q\|_q \|v\|_1 \|v\|_2 \leq C\alpha^{3/2}m_2,
\]
where the last inequality is obtained by replacing in (22) the norms of \( \varrho \) by \( \|\varrho\|_\infty \leq m_2 \) if \( q \geq \gamma \); for \( q < \gamma \) we can use the estimate for the \( L_\gamma \)-norm of \( \varrho \).

Summarising, we have shown that \( \|\nabla v\|_q \leq C(m_2, \alpha) \) with a constant \( C(m_2, \alpha) \) independent of \( \epsilon \). Particulary for \( 2 < q < \gamma \) one has
\[
\|\nabla v\|_q \leq C(\alpha + \alpha^{3/2} + \alpha^{3/q}m_2^{(1-2/q)\gamma}).
\] (24)
Before passing to the zero limit with \( \epsilon \) we will compute a priori estimate of the vorticity
\[
\omega = \text{rot} v = \frac{\partial v_2}{\partial x_1} - \frac{\partial v_1}{\partial x_2}.
\]
Differentiating \( n \cdot v = 0 \) at \( \partial \Omega \) with respect to the length parameter and combining it with the last boundary condition in the system (6) we obtain:

\[
\omega = \left(2 \chi - \frac{f}{\mu}\right) v \cdot \tau \text{ at } \partial \Omega.
\]

Taking the rotation of (6), we get

\[
-\mu \Delta \omega = -\text{rot}(hg - \varrho v) - \text{rot} div(K(\varrho)v \otimes v) - \text{rot} \nabla \varrho v).
\]

(25)

Denote

\[
\omega = \omega_1 + \omega_2,
\]

(26)

where \( \omega_1, \omega_2 \) satisfy:

\[
-\mu \Delta \omega_1 = -\text{rot div}(K(\varrho)v \otimes v) \text{ in } \Omega,
\]

\[
\omega_1 = 0 \text{ at } \partial \Omega,
\]

\[
-\mu \Delta \omega_2 = -\text{rot}(hg - \varrho v) - \text{rot} \nabla \varrho v) \text{ in } \Omega,
\]

\[
\omega_2 = \left(2 \chi - \frac{f}{\mu}\right) v \cdot \tau \text{ at } \partial \Omega.
\]

For the weak solutions \( \omega_1, \omega_2 \) of the above problems one get the following estimates:

\[
\|\omega_1\|_q \leq C\|K(\varrho)v \otimes v\|_q \leq C\alpha
\]

where for \( q < \gamma \), \( C \) is independent of \( m_2 \) and for \( q > \gamma \), \( C = C_0 m_2^{1-\gamma/q} \),

\[
\|\omega_2\|_{1,q} \leq C(\alpha\|hg\|_{q} + \alpha\|\varrho v\|_{q} + \epsilon\|\nabla \varrho v\|_{q}) + C(\Omega)\|v \cdot \tau\|_{1-1/q,q,\partial \Omega},
\]

thus for \( q < 2 \), the Hölder’s inequality, the imbedding \( W_2^{1/2}(\partial \Omega) \subset W_q^{1-1/q}(\partial \Omega) \) and the trace theorem imply

\[
\|\omega_2\|_{1,q} \leq C(\alpha\|hg\|_{\frac{2}{q}} + \alpha\|\varrho v\|_{\frac{2}{q}} + \epsilon\|\nabla \varrho\|_{2q/(2-q)}\|\nabla v\|_2 + C(\Omega)\|v\|_{1,2}
\]

\[
\leq C(\alpha + \alpha^2 m_2) + C(\Omega)\alpha^{1/2},
\]

for \( q \geq 2 \) we must use \( m_2 \)-dependent estimates of gradient of \( v \) in higher norms, thus

\[
\|\omega_2\|_{1,q} \leq C(\alpha, m_2)
\]

and the dependence of \( m_2 \) is higher then linear.

3 Passage to the limit

This section is devoted to the passage with \( \epsilon \rightarrow 0 \) in the system (6). Recall that so far we have obtained the following estimates:

\[
\|\varrho_\epsilon\|_{\infty} \leq m_2, \quad \|v_\epsilon\|_{1,2} \leq C\alpha, \quad (27)
\]

\[
\|P(\varrho_\epsilon)\|_2 \leq C\alpha^{3/2} \quad (28)
\]

\[
\|v_\epsilon\|_{1,q} + \epsilon^{1/2}\|\nabla \varrho_\epsilon\|_2 \leq C(m_2, \alpha) \quad \text{for } 1 \leq q < \infty, \quad (29)
\]

\[
\epsilon\|\nabla \varrho_\epsilon \nabla v_\epsilon\|_q \leq C(m_2, \alpha) \quad \text{for } 1 \leq q < \infty. \quad (30)
\]
The two last estimates together with the interpolation inequality imply that for $\delta$ sufficiently small we additionally have:

$$
\epsilon^{1-\delta} \| \nabla q_\epsilon \nabla v_\epsilon \|_q \leq C(m_2, \alpha) \quad \text{for} \quad 1 \leq q < \infty.
$$

Therefore, at least for an appropriately chosen subsequence:

\[
\begin{align*}
q_\epsilon & \rightharpoonup^* q \quad \text{in} \ L_\infty(\Omega), \\
P(q_\epsilon) & \rightharpoonup P(q) \quad \text{in} \ L_2(\Omega), \\
v_\epsilon & \rightharpoonup v \quad \text{in} \ W^1_q(\Omega), \\
\epsilon \nabla q_\epsilon & \to 0 \quad \text{in} \ L_2(\Omega), \\
\epsilon \nabla q_\epsilon \nabla v_\epsilon & \to 0 \quad \text{in} \ L_q(\Omega) \quad \text{for} \quad 1 \leq q < \infty,
\end{align*}
\]

where the line over a term denotes its weak limit.

These information allow us to pass to the limit in our approximative system:

\[
\begin{align*}
\alpha \left( q - hK(q) \right) + \text{div}(K(q)qv) & = 0 \\
\alpha (qv - hg) + \text{div}(K(q)qv \otimes v) - \mu \Delta v - (\mu + \nu) \nabla \text{div}v + \nabla P(q) & = 0 \\
v \cdot n = 0 & \quad \text{at} \quad \partial \Omega, \\
(\nu \cdot T(v, \overline{P(q)})) \cdot \tau + f v \cdot \tau & = 0 \quad \text{at} \quad \partial \Omega.
\end{align*}
\]

To show that we have really found the solution to our initial problem there left several questions that need to find the answer.

Firstly, if we can get rid of $K(q)$ that remains at several places, i.e. if we can prove that $K(q) = 1$ a.e. in $\Omega$. This, as we shall see below, is equivalent with showing that there can be suitably chosen constant $m$ sufficiently large but still sharply smaller than the it a priori bound for a density, such that the measure of the set

$$
\{ x \in \Omega : q_\epsilon(x) > m \}
$$

tends to zero for some subsequence $\epsilon_n \to 0^+$. Indeed, as this implies that for any smooth function $\eta$ one get

$$
\int_\Omega q_\epsilon K(q_\epsilon) \eta \ dx = \int_\Omega q_\epsilon \eta \ dx + \int_{\{q_\epsilon > m_1\}} (K(q_\epsilon) - 1) q_\epsilon \eta \ dx.
$$

If we choose $m_1$ sufficiently close to $m_2$ and additionally assure that $m < m_1$ then the last term on the right hand side disappears as $\epsilon_n$ goes to 0, and thus we truly have

$$
\lim_{\epsilon_n \to 0^+} \int_\Omega q_\epsilon K(q_\epsilon) \eta \ dx = \int_\Omega q \eta \ dx, \quad \forall \eta \in C^\infty(\Omega).
$$

The next difficulty concerns the convergence in the nonlinear term i.e. is it true that $\overline{P(q)} = P(q)$. The positive answer can be obtained in a rather standard way, and at the stage when one already knows that $K(q) = 1$ it reduces to proving the strong convergence for the density sequence.
Finally, what does the condition \((31)\) mean, in other words in which sense is it satisfied? Having solved the two previous problem this is quite easy to see that this boundary condition can be recovered while passing to the limit in a weak formulation corresponding to the momentum equation.

Now our aim will be to precisely justify the considerations developed above. For this purpose we will adapt a kind of technique widely used for these type of problems, more precisely we will take advantage of some properties of the effective viscous flux denoted in this paper by \(G\).

Introducing the Helmholtz decomposition of the velocity vector field defined as:

\[
v = \nabla \phi + \nabla^\perp A,
\]

(32)

where the divergence-free part \(\nabla^\perp A = \left(-\frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_1}\right) A\) and the gradient part \(\phi\) are given by:

\[
\begin{cases}
\Delta A = \text{rot} v & \text{in } \Omega,

\nabla^\perp A = 0 & \text{at } \partial \Omega,

\Delta \phi = \text{div} v & \text{in } \Omega,

\frac{\partial \phi}{\partial n} = 0 & \text{at } \partial \Omega,
\end{cases}
\]

(33)

we can transform the limit equation \((31)\) into the form:

\[
\nabla G = \alpha hg - \alpha \varrho v - \text{div}(\tilde{K}(\varrho)\varrho v \otimes v) + \mu \Delta \nabla^\perp A,
\]

(34)

where \(\nabla G = \nabla \left(-(2\mu + \nu)\Delta \phi + \tilde{P}(\varrho)\right)\). By the observation \(\int_\Omega G dx = \int_\Omega \tilde{P}(\varrho) dx \leq \infty\), we control the mean value of \(G\) and thus the expression

\[
G = (2\mu + \nu)\Delta \phi + \tilde{P}(\varrho)
\]

may be accepted as a correct definition of \(G\).

Due to \((33)\), and the classical theory for the laplacian supplemented by the Neumann-boundary condition

\[
\|G\|_2 \leq C(\|\nabla v\|_2 + \|\tilde{P}(\varrho)\|_2) \leq C(\alpha).
\]

The next goal is to show the boundedness of the \(L_\infty\) norm of \(G\). By the fact that the mean value of \(G\) is controlled we can employ the Poincare’s inequality and the Sobolev embedding theorem it is sufficient to prove the following fact:

**Lemma 6.** For \(q > 2\) we have:

\[
\|\nabla G\|_q \leq C(\alpha, m_2).
\]

(35)

**Proof.** By virtue of \((33)\)

\[
\|\nabla G\|_q \leq C\alpha \|hg\|_q + \alpha \|\varrho v\|_q + \|\text{div}(\tilde{K}(\varrho)\varrho v \otimes v)\|_q + \mu \|\Delta \nabla^\perp A\|_q.
\]

(36)

For \(q < \gamma\) may we certainly write that

\[
\alpha \|hg\|_q + \alpha \|\varrho v\|_q \leq C\alpha \|v\|_{1,2} \leq C\alpha^{3/2},
\]

14
by the continuity equation, the estimates (14) and (7) we get
\[ \| \text{div}(K(\bar{\rho})\bar{v} \otimes v) \|_q \leq \| K(\bar{\rho})\bar{v} \cdot \nabla v \|_q + \alpha \| K(\bar{\rho})v \|_q + \alpha \| qv \|_q \]
\[ \leq Cm_2 \| \nabla v \|_q^2 + C\alpha^{3/2}, \]
thus, the estimate (21) of \( \| \nabla v \|_q \) for \( \gamma > q > 2 \) leads to
\[ \| \text{div}(K(\bar{\rho})\bar{v} \otimes v) \|_q \leq C(\alpha^{3/2} + \alpha^2 + \alpha^3 + \alpha^{6/2}m_2^{1+2(1-2/q}\gamma) \]
The last term in (36) is bounded by the same constant, since
\[ \| \Delta \nabla^\perp A \|_q \leq \| \nabla \omega \|_q \leq \alpha \| hg \|_q + \alpha \| qv \|_q + \| \text{div}(K(\bar{\rho})\bar{v} \otimes v) \|_q + \]
\[ + C \| v \cdot \tau \|_{1-1/q,2+\delta,\partial \Omega}, \]
where \( \omega \) is a weak solution to (25) with a corresponding boundary condition after passing with \( \epsilon \) to 0, i.e. it satisfies
\[ -\mu \Delta \omega = -\alpha \text{rot}(hg - \bar{v}v) - \text{rot} \text{div}(K(\bar{\rho})\bar{v} \otimes v) \quad \text{in } \Omega \]
\[ \omega = \left( 2\chi - \frac{f}{\mu} \right) v \cdot \tau \quad \text{at } \partial \Omega. \]
\[ \square \]
For \( q \) such small that \( \gamma > 1 + 2(1-2/q)\gamma \) we have then proved that
\[ \| G \|_\infty \leq C(\alpha)m_2^{\gamma-\delta}, \] (37)
with \( \delta = \gamma(4/q - 1) - 1 > 0 \) and \( C(\alpha) = 6/q \)
We will now apply the analogical decomposition for the approximative system (6), i.e.
\( v_\epsilon = \nabla \phi_\epsilon + \nabla^\perp A_\epsilon \).
Similarly as previously this leads to relation
\[ \nabla G_\epsilon = (2\mu + \nu)\Delta \phi_\epsilon + P(\phi_\epsilon) \]
\[ = \alpha hg - \alpha \phi_\epsilon v_\epsilon - \text{div}(K(\phi_\epsilon)\phi_\epsilon v_\epsilon \otimes v_\epsilon) - \epsilon \nabla \phi_\epsilon \nabla v_\epsilon + \mu \Delta \nabla^\perp A_\epsilon. \] (38)
We are then able to prove that if \( \epsilon \to 0^+ \) the following lemma holds

**Lemma 7.** \( G_\epsilon \to G \text{ strongly in } L^2(\Omega). \)

**Proof.** We will use the following fact:

*If* \( \nabla(G_\epsilon - G) \to 0 \) in \( L^2 \), then \( G_\epsilon - G \to \text{const} \) in \( L^2 \),

and next we can show that at least for some subsequence \( \epsilon_n \to 0 \) the constant is indeed equal zero
\[ \int_\Omega (G_\epsilon - G) = \int_\Omega \Delta(\phi - \phi_\epsilon) \to 0 \]
since $\frac{\partial \phi}{\partial n} = \frac{\partial \phi_\epsilon}{\partial n} = 0$ at $\partial \Omega$.

This allows us to focus on showing the weak convergence, we have

$$\nabla (G_{\epsilon} - G) = \mu \Delta \nabla^\perp (A' - A) - \alpha (\phi_\epsilon v_\epsilon - \phi v)$$

$$- \left( \text{div} (K(\phi_\epsilon) \phi_\epsilon v_\epsilon \otimes v_\epsilon) - \text{div} (K(\phi) \phi v \otimes v) \right) - \epsilon \nabla \phi_\epsilon \nabla v_\epsilon. \quad (39)$$

The second term on the right hand side converges to 0 weakly in $L^2$ owing to the strong convergence of $v_\epsilon \to v$ in $L^q$ for any $0 \leq q \leq \infty$ and by the boundedness of $\phi_\epsilon$ in $L^\infty$.

The last term converges to zero even strongly in $L^2$. Now, by the continuity equation, the third term may be written in the form

$$\text{div} (K(\phi_\epsilon) \phi_\epsilon v_\epsilon \otimes v_\epsilon) - \text{div} (K(\phi) \phi v \otimes v) = \alpha h K(\phi_\epsilon) \phi_\epsilon v_\epsilon - K(\phi) \phi v \cdot \nabla v,$$

In order to substantiate, that the first term in (39) also tends to 0 we observe that $\epsilon \Delta \nabla^\perp (A' - A) = \nabla^\perp (\omega_\epsilon - \omega)$, and that the function $\omega_\epsilon - \omega$ satisfies the system of equations

$$-\mu \Delta (\omega_\epsilon - \omega) = - \alpha \text{rot} (\phi_\epsilon v_\epsilon - \phi v) - \text{rot} \text{div} (K(\phi_\epsilon) \phi_\epsilon v_\epsilon \otimes v_\epsilon - K(\phi) \phi v \otimes v)$$

$$- \epsilon \text{rot} (\nabla \phi_\epsilon \nabla v_\epsilon) \quad \text{in} \quad \Omega$$

$$\omega_\epsilon - \omega = \left( \frac{2\chi}{\mu} - \frac{J}{\mu} \right) (v_\epsilon - v) \cdot \tau \quad \text{at} \quad \partial \Omega.$$

Repeating the same reasoning as in case of (26) and above explications we can show, that $\nabla (\omega_\epsilon - \omega)$ consists of two parts. One of them converges to 0 strongly in $W^{-1}_2(\Omega)$ and the other converges weakly in $L^2(\Omega)$. Thus, by (40), we get the same for $\Delta \nabla^\perp (A' - A)$ and therefore the proof of lemma is complete.

---

Provided with these information we can show the final argument for $K(\phi)$ to be equal 1

**Lemma 8.** Let $\kappa > 0$ and let $m$ satisfy

$$\|G\|_{\infty}^{1/\gamma} < m < m_1 \quad \text{and} \quad \frac{m^{\gamma+1}}{m_2} - \|G\|_{\infty} - \alpha (2\mu + \nu) \geq \kappa > 0$$

then we have

$$\lim_{\epsilon_n \to 0^+} \{x \in \Omega : \phi_{\epsilon_n}(x) > m \} = 0.$$
Proof.
The difference with respect to the Lemma 4.3 from \[6\] is that the rate of convergence here clearly must depend on \(\alpha\) and thus we pass with \(\epsilon\) to 0 when \(\alpha\) is set.

First observe that the assumptions of our lemma are satisfied. Indeed, as the difference \(m_2 - \|G\|_{l/2}\) increases with \(m_2\). Next, we introduce a function \(M(\cdot) \in C^1(\mathbb{R})\) given by

\[
M(\rho) = \begin{cases} 
1 & \rho \leq m, \\
0 & \rho \geq m + 1, \\
\in (0,1) & \rho \in (m, m + 1),
\end{cases}
\]

where \(M'(\rho) < 0\) in \((m, m + 1)\) and \(m + 1 < m_1\).

We multiply the approximate continuity equation by \(M^l(\rho_\varepsilon)\) for some \(l \in \mathbb{N}\) and we observe

\[
\alpha \int \Omega M^l(\rho_\varepsilon) (\rho - hK(\rho)) \, dx + \int \Omega M^l(\rho_\varepsilon) \text{div}(K(\rho)\rho v) \, dx = \epsilon \int \Omega M^l(\rho_\varepsilon) \Delta \rho \, dx
\]

\[
= -\epsilon l \int \Omega M'(\rho_\varepsilon) M^{l-1}(\rho_\varepsilon) |\nabla \rho_\varepsilon|^2 \, dx \geq 0. \quad (41)
\]

By integrating the second term on the left hand side by parts twice (the boundary terms disappear due to the definition of \(M(\cdot)\)) one gets

\[
\int \Omega \left( \int_0^{\rho_\varepsilon} t M^{l-1}(t) M'(t) \, dt \right) \text{div} v_\varepsilon \, dx
\]

\[
\geq \frac{\alpha}{l} \int \Omega (hK(\rho_\varepsilon) - \rho_\varepsilon) \, dx + \frac{\alpha}{l} \int \Omega (\rho_\varepsilon - hK(\rho_\varepsilon)) (1 - M^l(\rho_\varepsilon)) \, dx.
\]

The first term on the right hand side cancels due to the Theorem \[3\]. We can replace \(\text{div} v_\varepsilon\) according to the definition of \(G_\varepsilon\), then we have

\[
\int \Omega \left( \int_0^{\rho_\varepsilon} t M^{l-1}(t) M'(t) \, dt \right) (G_\varepsilon - P(\rho_\varepsilon)) \, dx
\]

\[
\leq -\frac{\alpha(2\mu + \nu)}{l} \int \Omega (\rho_\varepsilon - hK(\rho_\varepsilon)) (1 - M^l(\rho_\varepsilon)) \, dx.
\]

Since \(M'(t)\) is negative, supported in \((m, m + 1)\) and \(m + 1 < m_1 \rightarrow m_2^-\) the following inequality holds true

\[
-m \int \Omega \left( \int_0^{\rho_\varepsilon} t M^{l-1}(t) M'(t) \, dt \right) P(\rho_\varepsilon) \, dx
\]

\[
\leq m_2 \int \Omega \left( - \int_0^{\rho_\varepsilon} t M^{l-1}(t) M'(t) \, dt \right) |G_\varepsilon| \, dx + \frac{\alpha(2\mu + \nu)}{l} \int \Omega |\rho_\varepsilon - hK(\rho_\varepsilon)| (1 - M^l(\rho_\varepsilon)) \, dx.
\]
After integration of the internal term we claim to conclusion that the above expression is different then 0 only for a subset of $\Omega$, $\{\varrho > m\}$, thus

$$
\frac{m}{m_2} \int_{\{\varrho > m\}} (1 - M^I(\varrho)) P(\varrho) \, dx
\leq \int_{\{\varrho > m\}} (1 - M^I(\varrho)) |G| \, dx + \frac{\alpha(2\mu + \nu)}{m_2} \int_{\{\varrho > m\}} |\varrho - hK(\varrho)| (1 - M^I(\varrho)) \, dx. \tag{42}
$$

Now for each $\delta > 0$ we can find such sufficiently large number $l \in \mathbb{N}$, $l = l(\delta, \epsilon)$ that

$$
\|M^I(\varrho_{\epsilon})\|_{L_2(\{\varrho_{\epsilon} > m\})} \leq \delta,
\tag{43}
$$

since $M(\varrho_{\epsilon})$ is less then 1 for $\varrho_{\epsilon} > m$. This allows us to rewrite the inequality (42) in the following form

$$
\frac{m^{\gamma+1}}{m_2} |\{\varrho_{\epsilon} > m\}| \leq \frac{m}{m_2} \|M^I(\varrho_{\epsilon})\|_{L_2(\{\varrho_{\epsilon} > m\})} \|P(\varrho_{\epsilon})\|_{L_2(\{\varrho_{\epsilon} > m\})}
+ C(|\Omega|) \|G - G_{\epsilon}\|_2 + \|G\|_\infty |\{\varrho_{\epsilon} > m\}| + \alpha(2\mu + \nu) \{\{\varrho_{\epsilon} > m\}|,
$$

where the term on the left is a consequence of the definition of $P(\cdot)$ and the limits of integration. By (43) and the bound (28) we therefore may write

$$
\left(\frac{m^{\gamma+1}}{m_2} - \|G\|_\infty - \alpha(2\mu + \nu) \right) |\{\varrho_{\epsilon} > m\}| \leq \frac{Cm}{m_2} \delta \alpha^{3/2} + C(|\Omega|) \|G - G_{\epsilon}\|_2.
$$

Under our assumptions, the expression in the brackets is separated from 0 and at least for a suitably chosen subsequence $\epsilon_n \to 0^+$ Lemma [7] guarantees that

$$
\lim_{\epsilon_n \to 0^+} |\{\varrho_{\epsilon_n} > m\}| \leq \frac{Cm}{m_2} \delta \alpha^{3/2}.
$$

As $\delta$ may be arbitrary small and $\alpha = const$, we truly have

$$
\lim_{\epsilon_n \to 0^+} |\{\varrho_{\epsilon_n} > m\}| = 0.
$$

This fact, as it was already mentioned before, completes justification that $K(\varrho) = 1$ a.e. in $\Omega$.

The second problem to solve was to show that $\overline{P(\varrho)} = P(\varrho)$. For this purpose we multiply the approximate continuity equation by the function $\ln \frac{m_2}{\varrho_{\epsilon} + \delta}$ for $\delta > 0$ and integrate over $\Omega$. Like in the proof of last lemma, we observe

$$
\alpha \int_{\Omega} \ln \frac{m_2}{\varrho_{\epsilon} + \delta} (\varrho - h) \, dx + \int_{\Omega} \ln \frac{m_2}{\varrho_{\epsilon} + \delta} \operatorname{div}(\varrho v) \, dx
= \epsilon \int_{\Omega} \ln \frac{m_2}{\varrho_{\epsilon} + \delta} \Delta \varrho \, dx = \epsilon l \int_{\Omega} \frac{\nabla \varrho_{\epsilon}}{\varrho_{\epsilon} + \delta}^2 \, dx \geq 0. \tag{44}
$$
Similarly as previously we integrate by parts, pass with $\delta \to 0^+$, substitute $G_\varepsilon$ from the definition and pass with $\epsilon \to 0^+$ to get

$$\int_\Omega P(\varrho)\varrho \, dx + (2\mu + \nu)\alpha \int_\Omega (\varrho - h)\ln \varrho \, dx \leq \int_\Omega G\varrho \, dx. \quad (45)$$

From now on we will seek to reverse the sign of above inequality. We will use the fact that the limit continuity equation works with any smooth function up to the boundary. To indicate an appropriate one we first introduce the distribution:

$$v \cdot \nabla \varrho = \text{div}(\varrho v) - \varrho \text{div} v.$$ 

Then let us recall the following lemma (for the proof consult [7]).

**Lemma 9.** Let $\Omega \in C^{0,1}$, $v \in W^1_q(\Omega)$, $\varrho \in L_p(\Omega)$, $1 < p, q < \infty$, $v \cdot \nabla \varrho \in L_s(\Omega)$, $1/s = 1/p + 1/q$. Then there exists $\varrho_n \in C^\infty(\Omega)$ such that

$$v \cdot \nabla \varrho_n \to v \cdot \nabla \varrho \text{ in } L_s(\Omega) \quad \text{and} \quad \varrho_n \to \varrho \text{ in } L_p(\Omega).$$

For such a $\varrho_n$ one gets

$$\int_\Omega \text{div}(\varrho_n v) \, dx = \int_{\partial \Omega} \varrho_n v \cdot n \, dS = 0,$$

thus passing with $n \to \infty$ our lemma provides that

$$\int_\Omega \varrho \text{div} v \, dx = -\int_\Omega v \cdot \nabla \varrho \, dx.$$

Note that a function $\ln \frac{\delta}{\varrho_n + \delta}$ for $\delta > 0$ is an admissible test function as it follows from the proof of Lemma [9] that $0 \leq \varrho_n \leq m_2$, hence we get

$$\alpha \int_\Omega (h - \varrho) \ln \frac{\varrho_n + \delta}{\varrho + \delta} = \int_\Omega \varrho v \cdot \nabla \varrho_n.$$

We may now pass with $n \to \infty$

$$\alpha \int_\Omega (h - \varrho) \ln \frac{\delta}{\varrho + \delta} = \int_\Omega \varrho \cdot \nabla \varrho.$$

Next we also want to pass with $\delta \to 0^+$, since $\int_\Omega (\varrho - h) \ln \delta \, dx = 0$, the only difficult term is $\alpha \int_\Omega h \ln(\varrho + \delta)$, but it can be solved by the Lebesgue monotone convergence theorem, then we obtain

$$\alpha \int_\Omega h \ln \varrho = \alpha \int_\Omega \varrho \ln \varrho - \int_\Omega v \cdot \nabla \varrho = \alpha \int_\Omega \varrho \ln \varrho + \int_\Omega \varrho \text{div} v.$$
Finally, recalling the definition of $G$ one gets
\[ \int_{\Omega} G \varrho \, dx = (2\mu + \nu) \alpha \int_{\Omega} (\varrho - h) \ln \varrho \, dx + \int_{\Omega} P(\varrho) \varrho \, dx. \] (46)

The information contained in (45), (46) together imply
\[ \int_{\Omega} P(\varrho) \varrho \, dx + (2\mu + \nu) \alpha \int_{\Omega} (\varrho - h) \ln \varrho \, dx \leq (2\mu + \nu) \alpha \int_{\Omega} (\varrho - h) \ln \varrho \, dx + \int_{\Omega} P(\varrho) \varrho \, dx. \] (47)

The convexity of functions $\varrho \ln(\varrho)$ and $-h \ln(\varrho)$ ensure lower semicontinuity of the functional $\int_{\Omega} (\varrho - h) \ln(\varrho) \, dx$, in other words
\[ \int_{\Omega} (\varrho - h) \ln \varrho \, dx \leq \int_{\Omega} (\varrho - h) \ln \varrho \, dx. \] (48)

Therefore (47) reduces to
\[ \int_{\Omega} P(\varrho) \varrho \, dx \leq \int_{\Omega} P(\varrho) \varrho \, dx. \] (49)

By the 'standard arguments' we show that $\overline{\varrho} \varrho \leq \overline{\varrho}^{\gamma+1}$ which together with (49) yield
\[ \overline{\varrho}^\gamma \varrho = \overline{\varrho}^{\gamma+1}. \] (50)

Next, we may also show that $\overline{\varrho}^{(\gamma+1)/\gamma}(x) \leq \overline{\varrho}^{\gamma+1}(x)$ and $\varrho(x) \leq \overline{\varrho}^{1/\gamma}$ for a.a. $x \in \Omega$ which easily imply that
\[ \overline{\varrho}^\gamma(x) = \overline{\varrho}(x). \] (51)

Since $L_\gamma(\Omega)$ is a uniformly convex Banach Space for $\gamma > 1$, $\varrho_\kappa \to \varrho$ weakly in $L_\gamma(\Omega)$ and $\|\varrho_\kappa\|_\gamma \to \|\varrho\|_\gamma$ we may deduce, that $\varrho_\kappa \to \varrho$ strongly in $L_\gamma(\Omega)$. Thus in turn implies, that for some subsequence $\varrho_{\kappa_n} \to \varrho$ a.e. in $\Omega$ and the condition $\|\varrho_\kappa\|_{L_\infty(\Omega)}$ guarantees the uniform integrability of the sequence $\{\varrho_{\kappa_n}\}_{n=1}^\infty$ which together with the Vitali’s convergence theorem leads to the strong convergence of the approximate densities to the function $\varrho$ in $L_p(\Omega)$ for any $1 \leq p < \infty$.

Remark 10. The density obtained in the above procedure is bounded by $m$ as we could see in lemma [8]. Now, by taking $\kappa$ sufficiently small and $m_1, m_2$ sufficiently close to $m$ the estimate (37) for $q \to 2^+$ with condition imposed on the assumptions of Lemma [8] will imply that
\[ \|\varrho\|_\infty \leq C(\alpha)^{3/(\gamma-1)}, \]
in particular, $\|\varrho\|_\infty \leq C(\Delta t)^{-3}$.

Theorem [1] is proved.
4 Passage with $\Delta t \to 0^+$

In this section we wish to present the proof of Theorem 2, i.e. to demonstrate the passage with $\Delta t \to 0^+$. The two previous sections enable us to restrict attention to the case when the weak solution of the system (1)-(2) exists, as provided by Theorem 1. Our approach will be based on some estimates uniform with respect to the length of time interval $\Delta t$ that we are going to gain here too. The task requires to work in the Bochner Spaces, but first let us introduce suitable notation:

$$
\hat{\phi}(x, t) = \phi^k(x) + (t - k\Delta t)(t(k+1) - \phi^k) \left( \frac{\phi^k}{\Delta t} \right)(x)
$$

if $k\Delta t \leq t < (k+1)\Delta t$. \(52\)

This converts our original system into:

$$
\frac{\partial \hat{\varrho}}{\partial t} + \text{div}(\hat{\varrho} \hat{v}) = 0 \quad \text{in } \Omega,
\frac{\partial \hat{\varrho} \hat{v}}{\partial t} + \text{div}(\hat{\varrho} \hat{v} \otimes \hat{v}) - \mu \Delta \hat{v} - (\mu + \nu) \nabla \text{div} \hat{v} + \nabla \pi(\hat{\varrho}) = 0 \quad \text{in } \Omega,
\hat{v} \cdot n = 0 \quad \text{at } \partial \Omega,
\hat{v} \cdot T(\hat{\varrho}, \pi) \cdot \tau + f \hat{v} \cdot \tau = 0 \quad \text{at } \partial \Omega.
$$

(53)

Moreover, the estimates (13) and (16) from the previous section now read:

- $\hat{\varrho}, \hat{\varrho}$ are bounded in $L^{\infty}(0, T; L^\gamma(\Omega))$ (54)
- $\hat{\varrho}^2, \hat{\varrho}^2$ are bounded in $L^{\infty}(0, T; L^1(\Omega))$ (55)
- $\hat{\varrho}, \hat{\varrho}$ are bounded in $L^2(0, T; H^1(\Omega))$ (56)
- $\hat{\varrho}, \hat{\varrho}$ are bounded in $L^\infty(0, T; L^{\infty}(\Omega)) \cup L^2(0, T; L^r(\Omega))$ for $1 \leq r < \gamma$ and all the bounds are independent of $\Delta t$. (57)

Our next aim will be to reconstruct the estimation for the norm of pressure $\pi(\hat{\varrho}) = \hat{\varrho}^\gamma$ in $L_q(\Omega \times (0, T))$ for some $q > 1$. Unfortunately, as we have seen in (23), such an estimate might not be true while $q = 2$, but it turns out to work for $q = 1 + (1/\gamma)$. To show this we test the momentum equation with a function $\Phi$ of the form:

$$
\Phi^k = \mathcal{B}(\{\hat{\varrho}^k\} - \{\phi^k\}), \quad \text{in } \Omega,
\Phi^k = 0 \quad \text{at } \partial \Omega.
$$

From this testing we obtain the following identity:

$$
\int_\Omega (\hat{\varrho}^{k+1}) = \int_\Omega (\hat{\varrho}^{k}) - \int_\Omega \hat{\varrho}^k \hat{v}^k \varrho \hat{v}^k : \nabla \Phi^k + \mu \int_\Omega \nabla \hat{v}^k : \nabla \Phi^k + (\mu + \nu) \int_\Omega \text{div} \hat{v}^k \text{div} \Phi^k
$$

$$
+ \int_\Omega \frac{1}{\Delta t} (\hat{\varrho}^k \Phi^k - \hat{\varrho}^{k-1}) \Phi^k = \sum_{i=1}^5 I_i.
$$
Multiplying by $\Delta t$, summing over $k = 1, \ldots, M$ and employing our notation we get
\[
\int_0^T \int_\Omega \hat{\varphi}^{\gamma+1} = \int_0^T \int_\Omega (\hat{\varphi})^{\gamma} \{ \hat{\varphi} \} - \int_0^T \int_\Omega \hat{\varphi} \otimes \hat{\varphi} \cdot \nabla \hat{\Phi} + \mu \int_0^T \int_\Omega \nabla \hat{\varphi} : \nabla (\hat{\Phi} + (\mu + \nu)) \int_0^T \int_\Omega \text{div} \hat{\varphi} \text{div} \hat{\Phi}
\]
\[
+ \int_0^T \int_\Omega \frac{1}{\Delta t} (\hat{\varphi} \hat{\varphi} - \hat{\varphi} \hat{\varphi} (\cdot - \Delta t) \hat{\varphi} (\cdot - \Delta t)) \hat{\Phi} = \sum_{i=1}^{5} I_i. \hspace{1cm} (58)
\]

We go one with estimations for each of terms separately.

(i) Since $\hat{\varphi}$ is bounded in $L_\infty(L_1)$ and $L_\infty(L_\gamma)$ one gets
\[
I_1 = \int_0^T \int_\Omega (\hat{\varphi})^{\gamma} \{ \hat{\varphi} \} = \int_0^T \frac{1}{|\Omega|} \| \hat{\varphi} \|_{L_1(\Omega)} \| \hat{\varphi} \|_{L_\gamma(\Omega)} \leq CT.
\]

(ii) The Hölder’s inequality, (56) and (57) imply
\[
I_2 = -\int_0^T \int_\Omega \hat{\varphi} \otimes \hat{\varphi} \cdot \nabla \hat{\Phi} \leq \int_0^T \| \hat{\varphi} \|_{L_2(\gamma/(\gamma+1))} \| \hat{\varphi} \|_{L_2(\gamma+1)} \| \nabla \hat{\Phi} \|_{L_\gamma+1} \leq CT^{(\gamma-1)/2(\gamma+1)} \| \hat{\varphi} \|_{L_{\gamma+1}(L_{\gamma+1})}.
\]

(iii) Due to the properties of the Bogovskii functional $\| \nabla \Phi_k \|_p \leq c(p, \Omega) \| \Phi_k \|_p$, thus
\[
I_3 + I_4 = \mu \int_0^T \int_\Omega \nabla \hat{\varphi} : \nabla (\hat{\Phi} + (\mu + \nu)) \int_0^T \int_\Omega \text{div} \hat{\varphi} \text{div} \hat{\Phi} \leq \int_0^T \| \nabla \hat{\varphi} \|_{L_2} \| \nabla \hat{\Phi} \|_{L_\gamma+1}
\]
\[
\leq CT^{(\gamma-1)/2(\gamma+1)} \| \hat{\varphi} \|_{L_{\gamma+1}(L_{\gamma+1})}.
\]

(iv) By the assumption that $\gamma > 2$ we know that $\hat{\varphi} \hat{\varphi} \in L_2(0, T; L_2(\Omega))$ which is the special case of (57), hence by the continuity equation
\[
I_5 = \int_0^T \int_\Omega \frac{1}{\Delta t} (\hat{\varphi} \hat{\varphi} - \hat{\varphi} \hat{\varphi} (\cdot - \Delta t) \hat{\varphi} (\cdot - \Delta t)) \hat{\Phi}
\]
\[
= \int_0^T \int_\Omega \frac{\partial}{\partial t} \hat{\varphi} \hat{\varphi} \hat{\Phi} + \int_0^T \int_\Omega \frac{1}{\Delta t} \hat{\varphi} \hat{\varphi} (\cdot - \Delta t) \hat{\varphi} (\cdot - \Delta t) (\hat{\Phi} (\cdot - \Delta t) - \hat{\Phi})
\]
\[
\leq \sup_{0 \leq t \leq T} \int_\Omega | \hat{\varphi} \hat{\varphi} \hat{\Phi} | + \int_0^T \| \hat{\varphi} \hat{\varphi} (\cdot - \Delta t) \hat{\varphi} (\cdot - \Delta t) \|_{L_2(\Omega)} \| \hat{\varphi} (\cdot - \Delta t) \|_{L_2(\Omega)}
\]
\[
\leq C + \int_0^T \| \hat{\varphi} \|_{L_\gamma}^2 \| \hat{\varphi} \|_{L_2(\gamma/2-2)}^2 \leq C.
\]
All together leads to desired conclusion
\[ \| \hat{\varrho}(\gamma+1)(L_{\gamma+1}) \| \leq C (1 + T + T^{(\gamma+1)/2}) \| \hat{\varrho}(L_{\gamma+1}(L_{\gamma+1})) \],

in particular we have
\[ \sum_{k=1}^{M} \Delta t \| \varrho^k \|_{L_{\gamma+1}}^{\gamma+1} < C(T). \] (59)

We are now in a position to validate that as \( \Delta t \to 0 \) the following convergences hold:
\[ [\hat{\varrho} - \varrho(\cdot - \Delta t)] = [\hat{\varrho} - \varrho] \to 0 \text{ in } L_q(L_\gamma) \] (60)
for \( q \in [1, \infty) \)
\[ [\hat{\varrho} - \varrho(\cdot - \Delta t)] = [\hat{\varrho} - \varrho] \to 0 \text{ in } L_q(L_r), \] (61)
for \( \{q \in [1, \infty), r \in [1, \frac{2}{\gamma+1}] \} \cup \{q \in [1, 2), r \in [1, \gamma]\}, \)
\[ [\hat{\varrho} \otimes \hat{\vartheta} - \varrho \otimes \vartheta] \to 0 \text{ in } L_1(L_r) \cap L_4(L_1), \] (62)
for \( q \in [1, \infty) \) \( r \in [1, \gamma] \).

To see this it suffices to use the estimates [54-55, 56-57] together with the observation derived from (65), namely
\[ \| \hat{\varrho} - \varrho(\cdot - \Delta t) \|^2_{L_q(L_\gamma)} \leq \Delta t C, \] (63)
morover for the remaining term in (54) we also have
\[ \| \hat{\varrho} \hat{\vartheta} - \varrho \vartheta(\cdot - \Delta t) \|^2_{L_1(L_1)} \leq \Delta t C. \] (64)

From what has already been written we deduce that
\[ \hat{\varrho}, \hat{\varrho} \to \varrho \text{ weakly}^* \text{ in } L_\infty(L_\gamma), \text{ weakly in } L_{\gamma+1}((0, T) \times \Omega), \] (65)
\[ \hat{\vartheta} \to \vartheta \text{ weakly in } L_2(H^1). \] (66)

**Remark 11.** Since \( \hat{\varrho}, \hat{\vartheta} \) satisfy continuity equation [55], thus the sequence of functions \( f(t) = \int_\Omega \hat{\varrho} \hat{\vartheta} dx \) (t) is bounded and equicontinuous in \( C[0, T] \) for all \( \varphi \in C_\infty(\Omega), \varphi \cdot n = 0 \) at \( \partial \Omega \). Therefore, the Arzela-Ascoli theorem, the density argument and the convergence established in (64) yield the following
\[ \hat{\varrho}, \hat{\varrho} \to \varrho \text{ in } C_{\text{weak}}(L_\gamma). \] (67)

What is left is to show that we also have the corresponding convergence of the products \( \hat{\varrho} \hat{\vartheta}, \hat{\varrho} \hat{\vartheta} \otimes \hat{\vartheta} \). This can be done by repeated application of the following lemma.

**Lemma 12.** Let \( g^n, h^n \) converge weakly to \( g, h \) respectively in \( L_{p_1}(L_{p_2}), L_{q_1}(L_{q_2}) \) where \( 1 \leq p_1, p_2 \leq \infty \) and
\[ \frac{1}{p_1} + \frac{1}{q_1} = \frac{1}{p_2} + \frac{1}{q_2} = 1. \]

Let assume in addition that
\[ \frac{\partial g^n}{\partial t} \text{ is bounded in } L_1(W_1^{-m}) \text{ for some } m \geq 0 \text{ independent of } n \] (68)
\[ \| h^n - h^n(\cdot + \xi t) \|_{L_{q_1}(L_{q_2})} \to 0 \text{ as } |\xi| \to 0, \text{ uniformly in } n. \] (69)

Then \( g^n h^n \) converges to \( gh \) in the sense of distributions on \( \Omega \times (0, T) \).
For the proof we refer the reader to [5].

For our case, since \( \frac{\partial \bar{\rho}}{\partial t} \) is bounded in \( L_\infty(W_{2\gamma/(\gamma+1)}^{-1}) \) and \( \frac{\partial \bar{\rho} \bar{v}}{\partial t} \) is bounded in \( L_\infty(W_1^{-1}) + L_2(H^{-1}) \), the condition (68) is satisfied for \( g^n = \bar{\rho}, \bar{\rho} \bar{v} \) and \( m = 1 \) respectively. Additionally, we have that since \( h^n = \bar{v} \) is bounded in \( L_\infty(W^{-1}) + L_2(H^{-1}) \), the condition (69) is satisfied for \( g^n = \bar{\rho}, \bar{\rho} \bar{v} \) and \( m = 1 \) respectively. Additionally, we have that since \( h^n = \bar{v} \) is bounded in \( L_\infty(W^{-1}) + L_2(H^{-1}) \), the condition (69) also holds.

With this manner we see that \( \hat{\rho} \hat{v} \) converges weakly/weakly* in \( L_\infty(L_{2\gamma/(\gamma+1)}) \) and in \( L_2(L_r) \) for \( r \in [1, \gamma) \) to \( \rho v \) and that \( \hat{\rho} \hat{v} \otimes \hat{v} \) converges weakly in \( L_1(L_r) \cap L_q(L_1) \), for \( q \in [1, \infty) \) and \( r \in [1, \gamma) \) to \( \rho v \otimes v \). Thus, the relations (61) and (62) cause that we actually have

\[
\hat{\rho} \hat{v} \rightharpoonup \rho v \text{ weakly in } L_q(L_r)
\]

for \( \{ q \in [1, \infty), r \in [1, 2^{\frac{\gamma}{\gamma+1}}] \} \cup \{ q \in [1, 2), r \in [1, \gamma) \} \),

\[
\hat{\rho} \hat{v} \otimes \hat{v} \rightharpoonup \rho v \otimes v \text{ weakly in } L_1(L_r) \cap L_q(L_1),
\]

for \( q \in [1, \infty) \) and \( r \in [1, \gamma) \).

Having this we can pass to the (weak,weak*) limit as \( \Delta t \to 0^+ \) in the system (53) everywhere except in the terms corresponding to the pressure:

\[
\begin{align*}
\frac{\partial \bar{\rho}}{\partial t} + \text{div}(\bar{\rho} v) &= 0 \text{ in } \Omega, \\
\frac{\partial \bar{\rho} \bar{v}}{\partial t} + \text{div}(\bar{\rho} \bar{v} \otimes \bar{v}) - \mu \Delta \bar{v} - (\mu + \nu) \nabla \text{div} v + \nabla \pi(\bar{\rho}) &= 0 \text{ in } \Omega, \\
v \cdot n &= 0 \text{ at } \partial \Omega, \\
v \cdot T(v, \pi) \cdot \tau + f v \cdot \tau &= 0 \text{ at } \partial \Omega.
\end{align*}
\]

From now on we will be using the following denotation

\[
\mathcal{S}(\nabla v) = \mu(\nabla v + \nabla^\perp v) + \nu \text{div}_x v I,
\]

\[
\mathcal{S}(\nabla \hat{v}) = \mu(\nabla \hat{v} + \nabla^\perp \hat{v}) + \nu \text{div}_x \hat{v} I.
\]

The proof of strong convergence of \( \pi(\rho^k) = (\rho^k)_{\gamma} \) in \( L_1(\Omega \times (0, T)) \) is based on some properties of the double Riesz transform, defined on the whole \( \mathbb{R}^2 \) in the following way

\[
\mathcal{R}_{ij} = -\partial_{x_i}(-\Delta)^{-1}_{x} \partial_{x_j},
\]

where the inverse Laplacian is identified through the Fourier transform \( \mathcal{F} \) and the inverse Fourier transform \( \mathcal{F}^{-1} \) as

\[
(-\Delta)^{-1}(v) = \mathcal{F}^{-1} \left( \frac{1}{|\xi|^2} \mathcal{F}(v) \right).
\]

We will be using general results on such operators as continuity but also some facts concerning the commutators involving Riesz operators, being mostly a consequence of Div-Curl lemma [9] or that of Coifman-Mayer [11, 3]. The best overall reference here for both: auxiliary tools and the general idea of the proof is [3].

To take advantage of what we mentioned, there is a need to extended the system (53) to the whole \( \mathbb{R}^2 \), as this is where the definition of the operator \( \Delta_{x}^{-1} \) makes sense. We
first observe that it can easily be done so for the continuity equation as \( \hat{\rho} \hat{v} \cdot n = 0 \) at \( \partial \Omega \), hence
\[
\frac{\partial}{\partial t} \Omega \hat{\rho} + \text{div}(\Omega \hat{\rho} \hat{v}) = 0.
\] (73)

For the momentum equation (53), we check that
\[
\phi(t, x) = \psi(t) \zeta(x) \tilde{\phi}, \quad \tilde{\phi} = (\nabla_x \Delta_x^{-1})[1_{\Omega} \hat{\rho}], \quad \psi \in C_c^\infty((0, T)), \quad \zeta \in C_0^\infty(\Omega),
\]
is an admissible test function. This can be seen as a consequence of estimates (54, 55, 56, 57, 59) and by the fact that the operator \( \nabla_x \Delta_x^{-1} \) gives rise to the spatial regularity to its range comparing to its argument of one. Particularly, later on we will take advantage of that for \( \gamma > 2 \), the embedding \( W_\gamma^1(\Omega) \subset C(\Omega) \) together with Remark 11 imply
\[
(\nabla_x \Delta_x^{-1})[1_{\Omega} \hat{\rho}] \rightarrow (\nabla_x \Delta_x^{-1})[1_{\Omega} \rho] \quad \text{in} \ C([0, T] \times \Omega). \] (74)

Having disposed of this preliminary step, we can get the following integral identity
\[
\int_0^T \int_\Omega \psi \zeta \left( \hat{\rho} \hat{v} \partial_t \hat{\phi} + \hat{\phi} \hat{v} \otimes \hat{v} : \nabla_x \Delta_x^{-1} \nabla_x [1_{\Omega} \hat{\rho}] \right) \, dx \, dt = \sum_{i=1}^5 I_i \] (75)

where
\[
I_1 = \int_0^T \int_\Omega \psi \zeta \left( \hat{\rho} \hat{v} \partial_t \hat{\phi} + \hat{\phi} \hat{v} \otimes \hat{v} : \nabla_x \Delta_x^{-1} \nabla_x [1_{\Omega} \hat{\rho}] \right) \, dx \, dt,
\]
\[
I_2 = - \int_0^T \int_\Omega \psi \hat{\rho} \nabla_x \zeta \cdot \nabla_x \Delta_x^{-1} [1_{\Omega} \hat{\rho}] \, dx \, dt,
\]
\[
I_3 = \int_0^T \int_\Omega \psi S(\nabla \hat{v}) : \nabla_x \zeta \otimes \nabla_x \Delta_x^{-1} [1_{\Omega} \hat{\rho}] \, dx \, dt,
\]
\[
I_4 = - \int_0^T \int_\Omega \psi (\hat{\rho} \hat{v} \otimes \hat{v}) : \nabla_x \zeta \otimes \nabla_x \Delta_x^{-1} [1_{\Omega} \hat{\rho}] \, dx \, dt,
\]
\[
I_5 = - \int_0^T \int_\Omega \partial_t \psi \tilde{\rho} \hat{v} \cdot \nabla_x \Delta_x^{-1} [1_{\Omega} \hat{\rho}] \, dx \, dt.
\]

Analogically, if we test the limit momentum equation by the corresponding test function
\[
\varphi(t, x) = \psi(t) \zeta(x) \phi, \quad \phi = (\nabla_x \Delta_x^{-1})[1_{\Omega} \hat{\rho}], \quad \psi \in C_c^\infty((0, T)), \quad \zeta \in C_0^\infty(\Omega),
\] (76)
we get
\[
\int_0^T \int_\Omega \psi \zeta \left( \hat{\rho} \hat{v} + S(\nabla \hat{v}) : \nabla_x \Delta_x^{-1} \nabla_x [1_{\Omega} \hat{\rho}] \right) \, dx \, dt = \sum_{i=1}^5 I_i \] (77)
where

\[ I_1 = \int_0^T \int_\Omega \psi \zeta \left( \rho v \partial_t \phi + \rho v \otimes v : \nabla_x \Delta_x^{-1} \nabla_x \left[ 1 \Omega \theta \right] \right) \, dx \, dt, \]

\[ I_2 = -\int_0^T \int_\Omega \psi \theta \nabla_x \zeta \cdot \nabla_x \Delta_x^{-1} \left[ 1 \Omega \theta \right] \, dx \, dt, \]

\[ I_3 = \int_0^T \int_\Omega \psi S(\nabla v) : \nabla_x \zeta \otimes \nabla_x \Delta_x^{-1} \left[ 1 \Omega \theta \right] \, dx \, dt, \]

\[ I_4 = -\int_0^T \int_\Omega \psi (\rho v \otimes v) : \nabla_x \zeta \otimes \nabla_x \Delta_x^{-1} \left[ 1 \Omega \theta \right] \, dx \, dt, \]

\[ I_5 = -\int_0^T \int_\Omega \partial_t \psi \zeta \rho v \cdot \nabla_x \Delta_x^{-1} \left[ 1 \Omega \theta \right] \, dx \, dt. \]

The observation (74) together with the consequences of lemma 12 justify the convergences of the integrals \( I_2, \ldots, I_5 \) from (75) to their counterparts in (77). Thus we are left with the following identity

\[
\lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta \left( \theta \nabla \theta - S(\nabla \theta) : R[1 \Omega \theta] \right) \\
- \lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta \left( \theta v \partial_t \theta - \theta v \otimes \theta : R[1 \Omega \theta] \right) \, dx \, dt \\
= \int_0^T \int_\Omega \psi \zeta \left( \theta v \partial_t \theta - \theta v \otimes \theta : R[1 \Omega \theta] \right) \, dx \, dt \\
- \int_0^T \int_\Omega \psi \zeta \left( \rho v \partial_t \phi - \rho v \otimes v : R[1 \Omega \theta] \right) \, dx \, dt. \quad (78)
\]

By the continuity equation we obtain

\[ \partial_t \phi = R[1 \Omega \theta], \]

and the same we have for the test function in the approximate case, thus (78) may be
rewritten as
\[
\lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta (\hat{\theta}^\gamma \hat{\theta} - S(\nabla \check{v}) : \mathcal{R}[1_{\Omega} \hat{\theta}]) \, dx dt
\]
\[
- \lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta (\check{\theta} \hat{\theta} \mathcal{R}[1_{\Omega} \hat{\theta}] - \check{\theta} \otimes \check{v} : \mathcal{R}[1_{\Omega} \hat{\theta}]) \, dx dt
\]
\[
= \int_0^T \int_\Omega \psi \zeta (\hat{\theta}^\gamma \hat{\theta} - S(\nabla v) : \mathcal{R}[1_{\Omega} \hat{\theta}]) \, dx dt
\]
\[
- \int_0^T \int_\Omega \psi \zeta (\check{\theta} \hat{\theta} \mathcal{R}[1_{\Omega} \hat{\theta}] - \check{\theta} \otimes v : \mathcal{R}[1_{\Omega} \hat{\theta}]) \, dx dt. \tag{79}
\]

Now we will show that we actually have that the second terms on each of sides are equivalent as \(\Delta t\) goes to 0. For this purpose we will use the Feireisl’s lemma \([4]\) which is a consequence of the div-curl one.

**Lemma 13.** Let
\[
V_n \rightharpoonup V \quad \text{weakly in } L_p(\mathbb{R}^2),
\]
\[
r_n \rightharpoonup r \quad \text{weakly in } L_q(\mathbb{R}^2),
\]
where
\[
\frac{1}{p} + \frac{1}{q} = \frac{1}{s} < 1.
\]
Then
\[
V_n \mathcal{R}(r_n) - r_n \mathcal{R}(V_n) \rightharpoonup V \mathcal{R}(r) - r \mathcal{R}(V) \quad \text{weakly in } L_s(\mathbb{R}^2).
\]

We will apply this lemma to \(r_n = \hat{\theta}(t, \cdot), \ V_n = \hat{\theta} \check{v}(t, \cdot)\) after extending them by 0 on the rest of \(\mathbb{R}^2\) and noticing that they satisfy assumptions of the lemma for \(p = 2\gamma/(\gamma + 1), \ q = \gamma\). Therefore we can take \(s = \frac{2\gamma}{3+\gamma}\) and thus, for a.a \(t \in [0, T]\)
\[
\hat{\theta} \check{v} \mathcal{R}(\hat{\theta})(t) - \hat{\theta} \mathcal{R}(\hat{\theta})(t) \rightharpoonup \check{v} \mathcal{R}(\hat{\theta})(t) - \check{v} \mathcal{R}(\check{v})(t) \quad \text{weakly in } L_s(\Omega)
\]
if we aditionally assume that \(\gamma > 3\).

In view of this, the embedding \(L_{\frac{2\gamma}{3+\gamma}}(\Omega) \subset W_2^{-1}(\Omega)\) and \((66)\) we get that
\[
\lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta \check{v} (\hat{\theta} \mathcal{R}[1_{\Omega} \hat{\theta}] - \check{\theta} \hat{\theta} \mathcal{R}[1_{\Omega} \hat{\theta}]) \, dx dt
\]
\[
= \int_0^T \int_\Omega \psi \zeta v (\hat{\theta} \mathcal{R}[1_{\Omega} \hat{\theta}] - \check{\theta} \hat{\theta} \mathcal{R}[1_{\Omega} \hat{\theta}]) \, dx dt,
\]
\(27\)
and the relations (61) and (65) allow us to reduce (79) to

$$\lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta (\hat{\varrho}' \hat{\varrho} - \mathcal{S}(\nabla \hat{v}) : \mathcal{R}[1_\Omega \hat{\nu}]) \, dxdt = \int_0^T \int_\Omega \psi \zeta (\tilde{\varrho}' \tilde{\varrho} - \mathcal{S}(\nabla v) : \mathcal{R}[1_\Omega \tilde{\nu}]) \, dxdt. \quad (80)$$

Now observe that by the fact that $\zeta \in C_0^\infty (\Omega)$ we may integrate by parts the second term on the left hand side and we will get

$$\int_0^T \int_\Omega \psi \zeta S(\nabla \hat{v}) : \mathcal{R}[1_\Omega \hat{\nu}] \, dxdt = \int_0^T \int_\Omega \psi \left( \mathcal{R} : \left[ \zeta S(\nabla v) \right] - \zeta \mathcal{R} : \left[ S(\nabla v) \right], \hat{\nu} \right) \, dxdt. \quad (81)$$

With the same manner we can transform the corresponding term in the limit on the right hand side of (80). After passing with $\Delta t$ to the limit in (81) we get

$$\lim_{\Delta t \to 0} \int_0^T \int_\Omega \psi \zeta S(\nabla \hat{v}) : \mathcal{R}[1_\Omega \hat{\nu}] \, dxdt = \int_0^T \int_\Omega \psi (2\mu + \nu) \text{div} \hat{\nu} \, dxdt + \int_0^T \int_\Omega \psi \left( \mathcal{R} : \left[ \zeta S(\nabla v) \right] - \zeta \mathcal{R} : \left[ S(\nabla v) \right], \nu \right) \, dxdt. \quad (82)$$

where the precise form of last term on the right is a consequence of Div-Curl lemma. Therefore (80) reduces to

$$\int_0^T \int_\Omega \psi \zeta (\tilde{\varrho}' \tilde{\varrho} - \tilde{\varrho} \text{div}_x v) \, dxdt = \int_0^T \int_\Omega \psi \zeta (\tilde{\varrho}' \tilde{\varrho} - \tilde{\varrho} \text{div}_x v) \, dxdt.$$ 

and since the choice of functions $\psi$ and $\zeta$ was arbitrary we have that:

$$\tilde{\varrho}' \tilde{\varrho} - \tilde{\varrho} \text{div}_x v = \tilde{\varrho}' \tilde{\varrho} - \tilde{\varrho} \text{div}_x v. \quad (83)$$

Next, we take $\delta > 0$ and multiply the discrete version of the continuity equation by $\ln(\varrho^k + \delta)$. After integrating by parts over $\Omega$ one get

$$\frac{1}{\Delta t} \int_\Omega (\varrho^k - \varrho^{k-1}) \ln(\varrho^k + \delta) - \int_\Omega \varrho^k v^k \frac{\nabla \varrho^k}{\varrho^k + \delta} = 0.$$
By the Lebesgue monotone convergence theorem we can pass with $\delta \to 0^+$ and then integrate by parts once more to find

$$\frac{1}{\Delta t} \int_\Omega (\varrho^k - \varrho^{k-1}) \ln(\varrho^k) + \int_\Omega \text{div}(v^k) \varrho^k = 0.$$  

Recall that due to Theorem 1 we have $\int_\Omega \varrho^k = \int_\Omega \varrho^{k-1}$, thus whereas $x \ln(x)$ is a convex function above equality may be changed into

$$\frac{1}{\Delta t} \int_\Omega [\varrho^k \ln(\varrho^k) - \varrho^{k-1} \ln(\varrho^{k-1})] \, dx + \int_\Omega \text{div}(v^k) \varrho^k \leq 0. \quad (84)$$

Summing from $k = 1$ to $k = M$, multiplying by $\Delta t$ and using the notation (52) we transform (84) to

$$\int_\Omega \tilde{\varrho} \ln(\varrho)(T) \, dx + \int_0^T \int_\Omega \tilde{\varrho} \text{div}_x \tilde{v} \, dxdt \leq \int_\Omega \varrho \ln(\varrho)(0) \, dx,$$

thus after passing to the limit one get

$$\int_\Omega \tilde{\varrho} \ln(\varrho)(T) \, dx + \int_0^T \int_\Omega \tilde{\varrho} \text{div}_x \varrho \, dxdt \leq \int_\Omega \varrho \ln(\varrho)(0) \, dx, \quad (85)$$

For the limit momentum equation, we take advantage of the fact that it is satisfied in the whole space in sense of distributions, thus the solution is automatically a renormalised solution, i.e. it is allowed to multiply the equation by $\ln(\varrho + \delta)$. Then we integrate over $\Omega$, pass to the limit as $\delta$ goes to $0^+$ and integrate with respect to time to get

$$\int_\Omega \varrho \ln \varrho(T) \, dx + \int_0^T \int_\Omega \varrho \text{div}_x v \, dxdt = \int_\Omega \varrho \ln \varrho(0) \, dx.$$

By comparing the two results from (85) and (86) we get that

$$\int_\Omega \varrho \ln \varrho(T) \, dx + \int_0^T \int_\Omega \varrho \text{div}_x v \, dxdt \geq \int_\Omega \varrho \ln \varrho(T) \, dx + \int_0^T \int_\Omega \varrho \text{div}_x v \, dxdt.$$

As in the proof of previous theorem, by the 'standard arguments' we show that $\tilde{\varrho} \varrho \tilde{v} \leq \varrho^{\gamma+1}$ which together with (83) provide

$$\int_0^T \int_\Omega \varrho \text{div}_x v \, dxdt \geq \int_0^T \int_\Omega \varrho \text{div}_x v \, dxdt. \quad (87)$$
The two last informations joined give the desired information, namely
\[ \rho \ln \rho = \rho \ln \rho, \]
and finally, by the convexity of function \( x \ln x \), we obtain
\[ \lim_{\Delta t \to 0^+} \hat{\rho} = \rho \quad \text{a.e. in } (0, T) \times \Omega \]
that completes the proof of Theorem 2.

\[ \square \]

ACKNOWLEDGEMENTS

The author wishes to express her gratitude to Piotr Boguslaw Mucha and Milan Pokorný for suggesting the problem, stimulating conversations and help during preparation of the paper.

The author was supported by the International Ph.D. Projects Programme of Foundation for Polish Science operated within the Innovative Economy Operational Programme 2007-2013 funded by European Regional Development Fund (Ph.D. Programme: Mathematical Methods in Natural Sciences) and partly supported by the MN Grant No N N201 547438.
