AN ANALYTIC APPROACH TO CARDINALITIES OF SUMSETS

DÁVID MATOLCSI, IMRE Z. RUZSA, GEORGE SHAKAN, AND DMITRII ZHILEZOV

Abstract. Let $d$ be a positive integer and $U \subset \mathbb{Z}^d$ finite. We study

$$\beta(U) := \inf_{A,B \neq \emptyset \text{ finite}} \frac{|A + B + U|}{|A|^{1/2}|B|^{1/2}},$$

and other related quantities. We employ tensorization, which is not available for the
doubling constant, $|U + U|/|U|$. For instance, we show

$$\beta(U) = |U|,$$

whenever $U$ is a subset of $\{0,1\}^d$. Our methods parallel those used for the Prékopa-Leindler inequality, an integral variant of the Brunn-Minkowski inequality.

1. Introduction

The aim of this study is to understand the nature of structures in $\mathbb{Z}^d$, the presence of which implies that the sumset must be large. The archetype is Freiman’s theorem that if a set $A \subset \mathbb{Z}^d$ is proper $d$-dimensional, then

$$|A + A| \geq (d + 1)|A| - \binom{d + 1}{2}.$$  

The assumption on dimension can be expressed as $S_d \subset A$ for a $d$-dimensional simplex $S_d$. In general, the induced doubling of a set $U$ is the quantity

$$\inf_{A \supseteq U} \frac{|A + A|}{|A|};$$

our main aim is to give lower estimates for it and related quantities. Applications for the sum-product problem, related to the work of [BC04], will be the subject of another paper.

While our main interest is in $\mathbb{Z}^d$, we shall mostly formulate our results for general, typically torsion-free commutative groups. Since we work with finite sets and a finitely generated torsion-free group is isomorphic to some $\mathbb{Z}^d$, it is not more general, but we rarely need the coordinates.

In the first part we work with sets, in the second part we study a weighted version which will be necessary for the proof of the main results. By introducing a weighted analog, we will be able to use tensorization: that is we prove a $d$ dimensional inequality by induction on dimension alongside a two point inequality. This is a method commonly used in analysis, for instance in the Prékopa-Leindler inequality [Pre71] and Beckner’s inequality [Bec75]. We discuss this more below, but also invite the reader to the excellent survey paper of Gardner [Gar02].

Part I: sets
2. Main results

Let \( U \) be a finite set in a commutative group \( G \). We modify the above definition of induced doubling to use sums of different sets, which are often better behaved.

**Definition 2.1** (Induced doubling). The induced doublings of \( U \) are the quantities

\[
\alpha(U) = \inf_{A \supset U, B \supset U} \frac{|A + B|}{\sqrt{|A||B|}},
\]

the (unrestricted) induced doubling;

\[
\alpha'(U) = \inf_{A \supset U, B \supset U, |A| = |B|} \frac{|A + B|}{|A|},
\]

the isometric induced doubling;

\[
\alpha''(U) = \inf_{A \supset U} \frac{|A + A|}{|A|},
\]

the isomeric induced doubling.

**Conjecture 2.2.** In the above definitions, the infimum is a minimum.

We rarely can estimate induced doubling directly, typically it will be through a related quantity involving the sum of three sets.

**Definition 2.3** (Induced tripling \( \beta \)). The triplings of \( U \) are the quantities

\[
\beta(U) = \inf_{A, B} \frac{|A + B + U|}{\sqrt{|A||B|}},
\]

the (unrestricted) tripling;

\[
\beta'(U) = \inf_{A, B, |A| = |B|} \frac{|A + B + U|}{\sqrt{|A||B|}},
\]

the isometric tripling;

\[
\beta''(U) = \inf_{A} \frac{|A + A + U|}{|A|},
\]

the isomeric tripling.

These infima may and may not be minima. Estimates for \( \beta \) yield an estimate weaker than the obvious \( \max(|A|, |B|) \) when the sizes of \( A \) and \( B \) are rather different. We consider an asymmetric version as follows.

**Definition 2.4** (Asymmetric induced tripling \( \beta_p \)). For \( 1 < p < \infty \) we put

\[
\beta_p(U) = \inf_{A, B} \frac{|A + B + U|}{|A|^{1/p}|B|^{1-1/p}}.
\]

Thus \( \beta(U) = \beta_2(U) \). We shall estimate these quantities rather precisely for sets contained in quasicubes, which we define recursively as follows.

**Definition 2.5** (Quasicubes). A 0-dimensional quasicube is any singleton.

Let \( U \) be a finite set in a commutative group \( G \). We say that \( U \) is a \( d \)-dimensional quasicube, if there is a proper subgroup \( G' \) such that \( U \) is contained in two distinct cosets, say \( G' + x \) and \( G' + y \), both \( U \cap (G' + x) \) and \( U \cap (G' + y) \) are \( d-1 \)-dimensional quasicubes and \( x - y \) is of infinite order in the factor-group \( G/G' \).
For instance, in $\mathbb{Z}^2$ any four points that lie on two distinct parallel lines (i.e. a trapezoid) form a quasi-cube. A $d$-dimensional quasicube has $2^d$ elements, and its dimension is indeed $d$ according to the following definition.

**Definition 2.6 (Set dimension).** Let $A$ be a finite set in a commutative group $G$. Let $H$ be the subgroup generated by $A-A$, that is, the smallest group $H$ with the property that $A$ lies in a single coset of $H$. As a finitely generated group, $H$ is isomorphic to some $H' \times \mathbb{Z}^d$, where $H'$ is a torsion group. We call $d = \dim A$ the dimension of $A$.

The central result of the present paper is that subsets of quasicubes induce large additive doubling and tripling. Indeed much of what we prove was known for cubes in [GT06], but their geometric methods do not extend to quasi-cubes (or subsets of quasi-cubes).

**Theorem 2.7 (Subsets of quasicubes have maximal $\beta$).** Let $U$ be a $d$-dimensional quasicube in any commutative group. For every $V \subset U$ we have

$$\beta(V) = |V|, \quad \alpha(V) \geq |V|^{1/2}.$$ 

In particular

$$\beta(U) = 2^d, \quad \alpha(U) \geq 2^{d/2}.$$ 

A short streamlined self-contained proof of Theorem 2.7 can also be found in [GMR+]. The main innovation of the tripling $\beta$ is that it allows one to efficiently account for the additive expansion of the lower dimensional subsets (fibers) of $U$ in a recursive fashion. The core estimate is Theorem 11.1, where we show that a certain functional is minimized by geometric progressions.

In comparison, the authors of [BC04] implicitly analysed a quantity similar to $\alpha$ and had to resort to multi-scale dyadic pigeonholing leading to a significantly worse estimate. In particular, such an analysis would give non-trivial bounds only for well-balanced quasicubes with all the lower-dimensional fibers being of comparable size.

As a corollary of Theorem 2.7, it follows that iterated sumsets of quasicube sumsets grow logarithmically, which is essentially sharp.

**Corollary 2.8 (Quasi-cubes have large iterated sumset).** Let $U$ be a $d$-dimensional quasicube in any commutative group. For every $V \subset U$ and $k \geq 2$ we have

$$|(2^k - 1)V| \geq |V|^k.$$ 

*Proof.* The base case $k = 2$ follows from the definition of $\beta$ and Theorem 2.7. For larger $k$, one has

$$|(2^k - 1)V| = |(2^{k-1} - 1)V + (2^{k-1} - 1)V + V| \geq |(2^{k-1} - 1)V|\beta(V) \geq |V|^k.$$ 

The trivial bound

$$\beta(U) \leq \min(|U|, 2^d)$$

holds for any set $U$ of dimension $d$, so the induced tripling (i.e. $\beta$) of quasicube subsets is as large as it gets. We conjecture that this holds for a larger class of sets.
Conjecture 2.9 (Log-span conjecture). Let $V$ be a finite set with the property that for any $k \leq \dim V$ any $k$-dimensional subset of $V$ has at most $2^k$ elements. Then

\begin{equation}
\beta(V) = |V|
\end{equation}

and in particular

$$\alpha(V) \geq |V|^{1/2}.$$ 

We conjecture that in fact $\beta$ is determined by the linear dependence matroid of the set in question, in the following sense.

Conjecture 2.10 (Linear matroid conjecture). Let $U, V$ be finite sets of equal cardinality in any group, $\varphi : U \to V$ a bijection. If for every $U' \subset U$ we have $\dim \varphi(U') \leq \dim U'$, then $\beta(V) \leq \beta(U)$. In particular, if always $\dim \varphi(U') = \dim U'$, then $\beta(V) = \beta(U)$.

Note that Conjecture 2.9 would follow quickly from Conjecture 2.10 and Theorem 2.7.

Theorem 2.11 (Discrete Prékopa-Leindler for quasi-cubes). Fix $1 < p < \infty$ and let $q$ be the conjugate exponent defined via

$$\frac{1}{p} + \frac{1}{q} = 1.$$ 

Let $U$ be a $d$-dimensional quasicube in any commutative group and $V \subset U$. We have

$$\beta_p(V) \geq c_p^d |V|,$$

where $c_p = \frac{p^{1/p} q^{1/q}}{2} \leq 1$.

The flexibility of choosing $p$ allows us to deduce the following discrete Brunn-Minkowski inequality.

Corollary 2.12 (Discrete Brunn-Minkowski for quasi-cubes). Let $U$ be a subset of a $d$-dimensional quasicube in any commutative group. For any finite sets $A, B$ we have

$$|A + B + U|^{1/d} \geq \frac{|U|^{1/d}}{2^d} \left(|A|^{1/d} + |B|^{1/d}\right).$$

Note if $U$ is a quasi-cube, then $|U| = 2^d$, and we obtain

$$|A + B + U| \geq |A|^{1/d} + |B|^{1/d}.$$ 

This result was obtained for cubes by Green and Tao [GT06, Lemma 2.4]. Their methods, which rely on the continuous Brunn-Minkowski inequality, seem to not generalize to quasi-cubes. We remark that our results are somewhat in a similar spirit to that of [BDF+11, Section 5], where lower bounds for sumsets of subsets of $\{0, \ldots, M-1\}^d$ are provided.

Proof. Apply the inequality from Theorem 2.11

$$|A + B + U| \geq \frac{|U|^{d/p}}{2^d} |A|^{1/p} |B|^{1/q}$$

with the optimal choice of $p$ which is defined by

$$1/p = \frac{|A|^{1/d}}{|A|^{1/d} + |B|^{1/d}}.$$ 

\hfill $\square$

Theorem 2.11 can be viewed as a discrete Prékopa-Leindler inequality, which we recall (see also [Gar02, Theorem 4.2]).
Theorem 2.13 (Prékopa-Leindler [Pré71]). Let $0 < \lambda < 1$ and
\[ g, h, F : \mathbb{R}^d \to \mathbb{R}, \]
be non-negative measurable functions satisfying for all $x, y \in \mathbb{R}^d$
\[ F((1 - \lambda)x + \lambda y) \geq f(x)g(y). \]
Then
\[ \int F \geq ||f||_p||g||_q, \]
with $p = 1/\lambda$ and $1/p + 1/q = 1$.

Note that Theorem 2.13 can be used to deduce the Brunn-Minkowski inequality, in
a similar manner to Corollary 2.12. Theorem 2.11 can be interpreted to be a discrete
analogy of Theorem 2.13.

3. Inequalities between doublings and triplings

We conjecture that the defined six quantities are actually only two, and connected
by simple inequalities.

Conjecture 3.1 (Doubling-tripling conjecture). For every finite set $U$ in any commu-
tative group we have
\[ \alpha(U) = \alpha'(U) = \alpha''(U) \leq \beta(U) = \beta'(U) = \beta''(U) \leq \alpha(U)^2. \]

We list some properties.

Statement 3.2 (Basic Inequalities). Let $V$ be a finite set in a commutative group, $G$,
$|V| = n$, dim $V = d$. We have
\[ \alpha(V) \leq \alpha'(V) \leq \alpha''(V) \begin{cases} < 2^d, \\ \leq (n + 1)/2, \end{cases} \]
\[ d + 1 \leq \beta(V) \leq \beta'(V) \leq \beta''(V) \begin{cases} \leq 2^d, \\ \leq n. \end{cases} \]

Proof. The inequalities
\[ \alpha(V) \leq \alpha'(V) \leq \alpha''(V), \quad \beta(V) \leq \beta'(V) \leq \beta''(V), \]
follow immediately from the definitions. Taking $A = V$ in the definition of $\alpha''(V)$, we have
\[ \alpha''(V) \leq \frac{|V + V|}{|V|} \leq \frac{1}{|V|} \left( \frac{|V| + 1}{2} \right) = \frac{n + 1}{2}. \]
Taking $A = \{0\}$ in the definition of $\beta''(V)$, we find that
\[ \beta''(V) \leq |V| = n. \]
Since $V$ has dimension $d$, we may assume
\[ V \subset H' \times \mathbb{Z}^d. \]
Thus for large enough $N$, we have $V \subset A$, where
\[ A := H' \times \{-N, \ldots, N\}^d. \]
Since
\[ \frac{|A + A|}{|A|} \to 2^d \quad \text{as} \quad N \to \infty, \]
we find that \( \alpha''(V) \leq 2^d \). Also,
\[ A + A + V \subset H' \times \left\{ -2N - \max_{v \in V} |v|_\infty, \ldots, 2N + \max_{v \in V} |v|_\infty \right\}^d, \]
and so
\[ \beta''(V) \leq \frac{|A + A + V|}{|A|} \to 2^d \quad \text{as} \quad N \to \infty. \]

Note that \( \beta(V) \geq d + 1 \) follows from the more general Theorem 2.7 which we prove later.

\[ \square \]

**Statement 3.3** (Basic Inequalities II). For every finite set \( U \) in any commutative group we have

(3.1) \[ \alpha(U) \leq \beta(U), \quad \alpha'(U) \leq 4\beta'(U), \quad \alpha''(U) \leq 3\beta''(U), \]

(3.2) \[ \beta(U) \leq \alpha(U)^2, \quad \beta''(U) \leq \alpha(U)^3, \]

(3.3) \[ \alpha''(U) \leq \alpha(U)^2, \quad \beta''(U) \leq \beta''(2U) \leq \beta(U)^2. \]

**Proof.** We may assume \( U \subset G = H' \times \mathbb{Z}^d \). If \( d = 0 \), then all
\[ 1 = \alpha(U) = \alpha'(U) = \alpha''(U) = \beta(U) = \beta'(U) = \beta''(U), \]
so we may assume \( d \geq 1 \).

We first show the second inequality in (3.1). Let \( A, B \) be such that \( |A| = |B| \) and let \( k \) be a large integer. Since \( d \geq 1 \), we may choose a \( x \in G \) be such that the sets
\[ A + x, \ldots, A + kx, \]
are disjoint, and
\[ B + x, \ldots, B + kx, \]
are also disjoint. Put
\[ A' = U \cup \bigcup_{i=1}^{k} (A + ix), \quad B' = U \cup \bigcup_{i=1}^{k} (B + ix). \]

These sets satisfy
\[ U \subset A', B' \quad \text{and} \quad |A'| = |B'| \geq k|A|. \]

We have

(3.4) \[ A' + B' = (U + U) \cup \bigcup_{i=1}^{k} (A + U + ix) \cup \bigcup_{i=1}^{k} (B + U + ix) \cup \bigcup_{i=2}^{2k} (A + B + ix). \]

As \( |A + U|, |B + U|, |A + B| \) are all smaller than \( |A + B + U| \), we find
\[ |A' + B'| \leq |U + U| + (4k - 1)|A + B + U|. \]

Thus
\[ \frac{|A' + B'|}{|A'|} \leq \frac{|U + U|}{k|A|} + \left( 4 - \frac{1}{k} \right) \frac{|A + B + U|}{|A|}. \]
As this is true for any $A$ and $B$ with $|A| = |B|$, we find
\[
\alpha'(U) \leq \frac{|U + U|}{k} + 4\beta(U),
\]
and the second statement of (3.1) follows from letting $k \to \infty$.

The proof of the third statement of (3.1), that is $\alpha''(U) \leq 3\beta''(U)$, proceeds similarly. The only difference is we take $A = B$ so some parts of (3.4) coincide and the 4 is reduced to 3.

We could use the same approach to show $\alpha(U) \leq 4\beta(U)$. The proof below due to Thomas Bloom allows one to get rid of the factor. We need the following from [Pet12].

\textbf{Lemma 3.4} (Petridis). Let $X, Y, Z$ be finite subsets of a commutative group with the property that for all $X' \subset X$, we have
\[
\frac{|X' + Y|}{|X'|} \geq \frac{|X + Y|}{|X|}.
\]

Then
\[
|X + Y + Z||X| \leq |X + Y||X + Z|.
\]

Let $A, B \subset G$ be finite with the property that for any $A' \subset A$ and $B' \subset B$
\[
\frac{|A + B + V|}{|A|^{1/2}B|^{1/2}} \leq \frac{|A' + B + V|}{|A'|^{1/2}B|^{1/2}}, \quad \frac{|A + B + V|}{|A|^{1/2}B|^{1/2}} \leq \frac{|A + B' + V|}{|A|^{1/2}B'1^{1/2}}.
\]

By a standard limiting argument we may assume WLOG that the infimum in the definition of $\beta(V)$ is taken over $A, B$ satisfying (3.5). This implies in particular that for any $A' \subset A$
\[
\frac{|A + B + V|}{|A|} \leq \frac{|A' + B + V|}{|A'|}.
\]

Applying Lemma 3.3 with $X = A$, $Y = B + V$ and $Z = V$, we conclude
\[
|A + B + V + V||A| \leq |A + B + V||A + V|,
\]
and rearranging gives
\[
\frac{|A + V + B + V|}{|A + V|^{1/2}B + V|^{1/2}} \left( \frac{|B + V|^{1/2}|A|^{1/2}}{|B|^{1/2}|A + V|^{1/2}} \right) \leq \frac{|A + B + V|}{|A|^{1/2}B|^{1/2}}.
\]

Applying with the roles of $A$ and $B$ swapped, we also find
\[
\frac{|A + V + B + V|}{|A + V|^{1/2}B + V|^{1/2}} \left( \frac{|A + V|^{1/2}|B|^{1/2}}{|A|^{1/2}|B + V|^{1/2}} \right) \leq \frac{|A + B + V|}{|A|^{1/2}B|^{1/2}},
\]
and so
\[
\frac{|A + V + B + V|}{|A + V|^{1/2}B + V|^{1/2}} \leq \frac{|A + B + V|}{|A|^{1/2}B|^{1/2}}.
\]
Thus we conclude that
\[
\alpha(V) \leq \beta(V).
\]

For (3.2) and (3.3) we need Plünnecke’s inequality.

\textbf{Lemma 3.5} (Plünnecke). Let $X$ and $Y$ be subsets of a commutative group. Let $k$ be a positive integer and $|X + Y| = c|X|$. Then there is a $X' \subset X$ such that
\[
|X' + kY| \leq c^k|X'|.
\]

In particular,
Lemma 3.6 (Plünnecke). Let $X, Y$ be finite sets of an additive group. Then there is $X' \subset X$ such that

$$|Y + Y| \leq |X' + Y + Y| \leq |X'| \frac{|X + Y|^2}{|X|^2} \leq \frac{|X + Y|^2}{|X|}.$$

We now proceed to (3.2). Let $A, B$ be any sets containing $U$. After swapping the roles of $A$ and $B$, we may suppose $|A| \geq |B|$. By Lemma 3.5, there is an $A' \subset A$ such that

$$|A' + 2B| \leq \left( \frac{|A + B|}{|A|} \right)^2 |A'|.$$

As $A' + B + U \subset A' + 2B$, we conclude

$$\beta(U) \leq \frac{|A' + B + U|}{\sqrt{|A'||B|}} \leq \sqrt{\frac{|A'||A + B|^2}{|A||A||B|}} \leq \frac{|A + B|^2}{|A||B|}.$$

As $A$ and $B$ are arbitrary, we conclude

$$\beta(U) \leq \alpha(U)^2.$$

We approach the first inequality in (3.3) similarly. Let $A$ and $B$ be arbitrary sets containing $U$. Then by Lemma 3.6

$$\frac{|B + B|}{|B|} \leq \frac{|A + B|^2}{|A||B|},$$

and $\alpha''(U) \leq \alpha(U)^2$ follows.

We now proceed to the second statement of (3.2). Let $A$ and $B$ be sets containing $U$ with $|B| \leq |A|$. By Lemma 3.5 we may find an $A' \subset A$ such that

$$|B + B + U| \leq |A' + 3B| \leq \left( \frac{|A + B|}{|A|} \right)^3 |A|.$$

Dividing both sides by $|B|$ and using $|B| \leq |A|$ gives $\beta''(U) \leq \alpha(U)^3$.

We now proceed to the second statement of (3.3). First, $\beta''(U) \leq \beta''(2U)$ follows immediately from the definitions. Let $A, B$ be arbitrary with $|B| \leq |A|$. We find, by Lemma 3.5, a $B' \subset B$ such that

$$|B' + 2(A + U)| \leq \left( \frac{|A + B + U|}{|B|} \right)^2 |B'|,$$

and hence

$$\frac{|2A + 2U|}{|A|} \leq \frac{|A + B + U|^2}{|A||B|},$$

and so $\beta''(2U) \leq \beta(U)^2$ follows. \hfill \Box

Problem 3.7. How tight are these inequalities? For the discrete cube $K_d = \{0, 1\}^d$ we have $\beta(K_d) = 2^d$, $2^{d/2} \leq \alpha(K_d) \leq (3/2)^d$, so $\beta \leq \alpha^2$ is pretty tight, the exponent is definitely not lower than $\log 2 / \log(3/2)$. 
4. The independence problem

In the preceding sections we tacitly assumed that the ambient group \( G \) is fixed, and the sets \( A, B \) in the definition of the \( \alpha \)'s and \( \beta \)'s are taken from this group. Sometimes we shall consider different groups, and the possibility of dependence arises.

For this section we change the notations to \( \alpha(U, G) \), to indicate the ambient group (and similarly for all other parameters).

**Conjecture 4.1** (The independence hypothesis). Let \( G \) be a group, \( G' \) its subgroup, \( U \subset G' \) and let \( \vartheta \) be any of the functionals \( \alpha, \alpha', \alpha'', \beta, \beta', \beta'' \). We have
\[
\vartheta(U, G) = \vartheta(U, G').
\]

We cannot even answer Conjecture 4.1 even in the following simple special case. Let \( G = \mathbb{Z}^d \), and assume that \( U \subset p \cdot \mathbb{Z}^d \). Do we get the same values of \( \alpha, \alpha', \alpha'', \beta, \beta', \beta'' \) if we restrict \( A, B \) to be subsets of \( p \cdot \mathbb{Z}^d \)?

The only case where we can show this in generality is for \( \beta \).

**Theorem 4.2** (Independence for \( \beta \)). Let \( G \) be a group, \( G' \) its subgroup, \( U \subset G' \). We have
\[
\beta(U, G) = \beta(U, G').
\]

**Proof.** Take \( A, B \subset G \) and split them according to cosets of \( G' \), say
\[
A = \bigcup A_i, \quad B = \bigcup B_j.
\]
Assume that \( A_1 \) is the largest of the \( A_i \) and similarly for \( B \). The sets \( A_1 + B_j + U \) are disjoint (as \( j \) varies), and hence
\[
|A + B + U| \geq \sum_j |A_1 + B_j + U| \geq \beta(U, G') \sqrt{|A_1|} \sum_j \sqrt{|B_j|}.
\]
By symmetry of \( A \) and \( B \),
\[
|A + B + U| \geq \beta(U, G') \sqrt{|B_1|} \sum_i \sqrt{|A_i|}.
\]
Forming the geometric mean of the above two inequalities and using Hölder of the form
\[
\sum x_i^2 \leq (\max x_i) \sum x_i
\]
separately for the numbers \( |A_i| \) and \( |B_j| \), we obtain the desired result. \( \square \)

An important special case is easily seen.

**Statement 4.3** (Cartesian products with torsion). Let \( G \) be a group, \( G = G' \times H \) with \( H \) torsion-free, \( U \subset G' \) and let \( \vartheta \) be any of the functionals \( \alpha, \alpha', \alpha'', \beta, \beta', \beta'' \). We have
\[
\vartheta(U, G) = \vartheta(U, G').
\]
In particular this implies that by embedding \( \mathbb{Z}^d \) into \( \mathbb{Z}^k \) with \( k > d \) these values do not change.

**Proof.** If \( G' \) is a torsion group, then all these functionals have value 1. Assume this is not the case, and fix a \( g \in G' \) of infinite order.

Take \( A, B \subset G \). We are going to construct \( A', B' \subset G' \) such that
\[
|A' + B'| = |A + B|, \quad |A' + B' + U| = |A + B + U|,
\]
and the restrictions used to define $\alpha, \alpha', \alpha'', \beta, \beta''$ are preserved.

Let $H'$ be the subgroup of $H$ generated by the elements in the $H$-projection of $A \cup B$. Since $H$ is torsion-free, we have $H' \cong \mathbb{Z}^d$ for some $d$. Let $e_1, \ldots, e_d$ be a system of generators for $H'$. For fixed integers $m_1, \ldots, m_d$ (to be chosen later) define a homomorphism

$$\varphi : G' \times H' \to G'$$

by

$$\varphi(x, ye_1 + \ldots + yd e_d) = x + (m_1 y_1 + \ldots + m_d y_d) g.$$ 

Put $A' = \varphi(A), B' = \varphi(B)$. It is clear that for $m_1, \ldots, m_d$ large enough (and dependent on $A, B, U$), $\varphi$ is one-to-one on $A, B, A + B, A + B + U$ and the claim follows. \hfill \Box

5. Torsion

The presence of torsion is the source of difficulties. We conjecture it should not matter much.

**Conjecture 5.1.** Let $G$ be a group, $H$ its torsion subgroup, $G' = G/H$ the factor group, $\varphi : G \to G'$ the natural homomorphism, $U \subset G$, $U' = \varphi(U) \subset G'$ and let $\vartheta$ be any of the functionals $\alpha, \alpha', \alpha'', \beta, \beta'$. We have

$$\vartheta(U') = \vartheta(U).$$

**Remark 5.2.** The case of $\beta$ follows from Statement 5.3 below and supermultiplicativity (Theorem 7.4) as $\beta$ is always at least 1.

**Statement 5.3** (Projections and torsion). Let $G$ be a group, $H$ its torsion subgroup, $G' = G/H$ the factor group, $\varphi : G \to G'$ the natural homomorphism, $U \subset G$, $U' = \varphi(U) \subset G'$ and let $\vartheta$ be any of the functionals $\alpha, \alpha', \alpha'', \beta, \beta', \beta''$. We have

$$\vartheta(U') \geq \vartheta(U).$$

**Proof.** For concreteness, let us prove Statement 5.3 for the case of $\beta$, as for the other functionals the argument is similar.

For an arbitrary $\epsilon > 0$ there are $A', B' \subset G'$ such that

$$\frac{|A' + B' + U'|}{|A'|^{1/2}|B'|^{1/2}} \leq \beta(U') + \epsilon.$$ 

WLOG we may assume $H$ is of finite order. Take $A := \phi^{-1}(A')$ and $B := \phi^{-1}(B')$, so that $|A| = |H||A'|$ and $|B| = |H||B'|$. At the same time clearly

$$|A + B + U| \leq |A' + B' + U'||H|,$$

so

$$\beta(U) \leq \frac{|A + B + U|}{|A|^{1/2}|B|^{1/2}} \leq \beta(U') + \epsilon.$$ 

The claim follows as $\epsilon$ can be taken arbitrarily close to zero. \hfill \Box

**Statement 5.4** (The trivial lower bounds). Let $G$ be a group, $H$ its torsion subgroup, $U \subset G$. If $U$ is contained in a single coset of $H$, then

$$\alpha(U) = \alpha'(U) = \alpha''(U) = \beta(U) = \beta'(U) = \beta''(U) = 1,$$

otherwise

$$\beta(U) \geq 2, \ \alpha(U) \geq 3/2.$$
Proof. The statement is trivial when \( U \) is contained in a coset of \( H \).

Otherwise, we may assume WLOG that \( U \) contains the union of \( \{0\} \oplus U_0 \) and \( \{1\} \oplus U_1 \) with some \( U_0, U_1 \subset G/\mathbb{Z} \). We also write

\[
A = \bigcup_{i=1}^{N} a_i \oplus A_i
\]

and

\[
B = \bigcup_{j=1}^{M} b_j \oplus B_j
\]

with \( A_i, B_j \subset G/\mathbb{Z} \) and some \( N, M \), so that the integers \( \{a_i\} \) and \( \{b_j\} \) are monotone increasing. Then \(|A + B + U|\) contains the disjoint union of

\[
(a_1 + b_1) \oplus (A_1 + B_1 + U_0),
\]

\[
(a_1 + b_1 + 1) \oplus (A_1 + B_1 + U_1),
\]

\[
(a_N + b_1 + 1) \oplus (A_N + B_1 + U_1),
\]

\[
(a_N + b_2 + 1) \oplus (A_N + B_2 + U_1),
\]

\[
(a_N + b_M + 1) \oplus (A_N + B_M + U_1).
\]

Since in any group

\[
|A_i + B_j + U_k| \geq \max\{|A_i|, |B_j|\},
\]

we conclude that

\[
|A + B + U| \geq \sum_{i=1}^{N} |A_i| + \sum_{j=1}^{M} |B_j| = |A| + |B| \geq 2|A|^{1/2}|B|^{1/2}.
\]

In a similar way, for an arbitrary \( A \supset U \) holds

\[
|A + B| \geq |A| + |B| - \min\{|A_1|, |A_N|, |B_1|, |B_M|\} \geq \frac{3}{2}|A|^{1/2}|B|^{1/2},
\]

and hence \( \beta(U) \geq 2 \) and \( \alpha(U) \geq 3/2. \) \( \square \)

6. Projection and Compression

By projection we mean the application of any homomorphism. We think projections never increase the value of our \( \alpha \)'s and \( \beta \)'s.

Conjecture 6.1 (Projection conjecture). Let \( G \) be a group, \( H \) its subgroup, \( G' = G/H \) the factor group, \( \varphi : G \to G' \) the natural homomorphism, \( U \subset G, U' = \varphi(U) \subset G' \) and let \( \vartheta \) be any of the functionals \( \alpha, \alpha', \alpha'', \beta', \beta'' \). We have

\[
\vartheta(U') \leq \vartheta(U).
\]

Remark 6.2. For \( \beta_p \) the conjecture follows from Theorem 7.5 as \( \beta_p \geq 1 \) always.

Remark 6.3. Essentially this means the following. Given sets \( A, B \subset G \) (subject to certain conditions, depending on which of the functionals we consider) we need to find \( A', B' \subset G' \) such that

\[
\frac{|A' + B'|}{\sqrt{|A'||B'|}} \leq \frac{|A + B|}{\sqrt{|A||B|}}
\]

for the \( \alpha \)'s, or

\[
\frac{|A' + B' + U'|}{|A'|^{|1/p|} |B'|^{1-1/p}} \leq \frac{|A + B + U|}{|A|^{1/p} |B|^{1-1/p}}
\]
for the $\beta$’s. The natural approach of taking $A' = \varphi(A)$, $B' = \varphi(B)$ may not work even when $G = \mathbb{Z}^2$, $G' = \mathbb{Z}$.

We establish an important special case.

**Theorem 6.4** (Projection conjecture with no torsion). Let $G$ be a group, $H$ its subgroup, $G' = G/H$ the factor group, $\varphi : G \to G'$ the natural homomorphism, $U \subset G$, $U'' = \varphi(U) \subset G'$ and let $\vartheta$ be any of the functionals $\alpha, \alpha', \alpha'', \beta, \beta', \beta''$. If $H$ is torsion-free, then

$$\vartheta(U') \leq \vartheta(U).$$

**Definition 6.5.** Let $G$ be a group, $H$ its subgroup, $G' = G/H$ the factor group, $\varphi : G \to G'$ the natural homomorphism. The compression along $\varphi$ of finite subsets of $G$ into finite subsets of $G' \times \mathbb{Z}$ defined as follows. Let $A \subset G$ be a finite set. We put

$$C_\varphi(A) = \bigcup_{x \in \varphi(A)} \{x \times \{0, 1, \ldots, |A \cap \varphi^{-1}(x)| - 1\}\}.$$ 

That is, each part of $A$ in a coset of $H$ is replaced by an interval of the same size. If $G = \mathbb{Z}^d$ and $H = \mathbb{Z}^k$ with $k < d$, then we can naturally represent the compression in $\mathbb{Z}^d$, which is the classical usage of this term. In what follows we will write $\varphi_{\mathbb{A}}^{-1}(x)$ as an alias for $\varphi^{-1}(x) \cap A$. For a given set $A$ and $x \in G'$, such a set is called the fiber of $A$ above $x$. One can say that the compression operator “normalizes” each fiber of $A$ by replacing it with an initial segment in $\mathbb{Z}$.

Clearly $|C_\varphi(A)| = |A|$ always.

**Statement 6.6** (Compressions shrink sumsets). Let $G$ be a group, $H$ its subgroup, $G' = G/H$ the factor group, $\varphi : G \to G'$ the natural homomorphism, $A, B \subset G$. If $H$ is torsion-free, then

$$C_\varphi(A) + C_\varphi(B) \subset C_\varphi(A + B).$$

**Proof.** The claim is standard and can be adopted from e.g. [GG01].

Let $z \in \varphi(C_\varphi(A) + C_\varphi(B))$. There are $z_a \in \varphi(A)$ and $z_b \in \varphi(B)$ such that $z = z_a + z_b$. By the Cauchy-Davenport inequality and the definition of the compression,

$$|\varphi^{-1}_A(z_a)| + |\varphi^{-1}_B(z_b)| - 1 \leq |\varphi^{-1}_A(z_a) + \varphi^{-1}_B(z_b)| \leq |\varphi^{-1}_{\varphi(A + B)}(z)|,$$

and the claim follows. $\square$

**Theorem 6.7** (Compressions). Let $G$ be a group, $H$ its subgroup, $G' = G/H$ the factor group, $\varphi : G \to G'$ the natural homomorphism, $U \subset G$, and let $\vartheta$ be any of the functionals $\alpha, \alpha', \alpha'', \beta, \beta', \beta''$. If $H$ is torsion-free, then

$$\vartheta(C_\varphi(U)) \leq \vartheta(U).$$

**Proof.** Indeed, the previous statement implies that

$$\frac{|C_\varphi(A) + C_\varphi(B)|}{\sqrt{|C_\varphi(A)||C_\varphi(B)|}} \leq \frac{|A + B|}{\sqrt{|A||B|}},$$

and

$$\frac{|C_\varphi(A) + C_\varphi(B) + C_\varphi(U)|}{|C_\varphi(A)|^{1/p}|C_\varphi(B)|^{1-1/p}} \leq \frac{|A + B + U|}{|A|^{1/p}|B|^{1-1/p}}.$$ 

Also, the restrictions are preserved (if $A \supset U$, then $C_\varphi(A) \supset C_\varphi(U)$; if $|A| = |B|$, then $|C_\varphi(A)| = |C_\varphi(B)|$). $\square$
**Proof of Theorem 6.4.** We can naturally embed \( G' \) into \( G' \times \mathbb{Z} \) as \( G' \times \{0\} \). With this embedding we have \( U' \subseteq C_\varphi(U) \), hence

\[
\vartheta(U, G) \geq \vartheta(C_\varphi(U), G' \times \mathbb{Z}) \geq \vartheta(U', G' \times \mathbb{Z}) = \vartheta(U', G');
\]

in the last step we apply Statement 4.3. \( \square \)

### 7. Direct Product

The behaviour of our quantities under direct product and a somewhat more general operation (tensorization, see Theorem 7.5 below) is important for our applications.

**Conjecture 7.1** (Multiplicativity hypothesis). Let \( G = G_1 \times G_2 \), \( V_1 \subseteq G_1 \), \( V_2 \subseteq G_2 \), \( U = V_1 \times V_2 \), and let \( \vartheta \) be any of the functionals \( \alpha, \alpha', \alpha'', \beta, \beta', \beta'' \). We have

\[
\vartheta(U) = \vartheta(V_1) \vartheta(V_2).
\]

Submultiplicativity is easy.

**Statement 7.2** (Sub-multiplicativity). Let \( G = G_1 \times G_2 \), \( V_1 \subseteq G_1 \), \( V_2 \subseteq G_2 \), \( U = V_1 \times V_2 \), and let \( \vartheta \) be any of the functionals \( \alpha, \alpha', \alpha'', \beta, \beta', \beta'' \). We have

\[
\vartheta(U) \leq \vartheta(V_1) \vartheta(V_2).
\]

**Proof.** We show only for \( \vartheta = \alpha \), the rest being similar. Let \( A_1, B_1 \) be arbitrary sets containing \( V_1 \) and \( A_2, B_2 \) be arbitrary sets containing \( V_2 \). Then \( A_1 \times A_2 \) and \( B_1 \times B_2 \) contain \( V_1 \times V_2 \) and so

\[
\alpha(V_1 \times V_2) \leq \frac{|A_1 \times A_2 + B_1 \times B_2|}{(|A_1||B_1||A_2||B_2|)^{1/2}} = \frac{|A_1 + B_1||A_2 + B_2|}{(|A_1||B_1||A_2||B_2|)^{1/2}}.
\]

Thus

\[
\alpha(V_1 \times V_2) \leq \alpha(V_1)\alpha(V_2). \tag*{\square}
\]

The multiplicativity hypothesis, Conjecture 7.1 would have consequences for the comparison problems of Section 3.

**Statement 7.3.** Let \( U \) be a subset of a commutative group.

If Conjecture 7.1 holds for \( \alpha' \), then \( \alpha(U) = \alpha'(U) \leq \beta'(U) \).

If Conjecture 7.1 holds for \( \alpha'' \), then \( \alpha''(U) \leq \beta''(U) \).

If Conjecture 7.1 holds for \( \beta' \), then \( \beta(U) = \beta'(U) \).

**Proof.** The inequalities

\[
\alpha'(U) \leq \beta'(U), \quad \alpha''(U) \leq \beta''(U),
\]

follow from (3.1), that is

\[
\alpha'(U) \leq 4\beta'(U), \quad \alpha''(U) \leq 3\beta''(U),
\]

and Conjecture 7.1 with the tensor power trick. We prove only the first of the two inequalities, the second following similarly. Indeed for any \( n \geq 1 \), first using Conjecture 7.1 for \( \alpha' \) and then Statement 7.2 for \( \beta' \), we find

\[
\alpha'(U)^n = \alpha'(U^n) \leq 4\beta'(U^n) \leq 4\beta'(U)^n.
\]

Thus

\[
\alpha'(U) \leq 4^{1/n}\beta'(U),
\]
and the result follows from allowing \( n \to \infty \). We now show that Conjecture 7.1 implies
\[
\alpha(U) = \alpha'(U).
\]
By Statement 3.2, it is enough to show \( \alpha'(U) \leq \alpha(U) \). Let \( A \) and \( B \) be sets containing \( U \). Then \( A \times B \) and \( B \times A \) contain \( U \times U \) and are of the same size, so
\[
\alpha'(U^2) \leq \frac{|A \times B + B \times A|}{|A||B|} = \frac{|A + B|^2}{|A||B|}.
\]
The result then follows from Conjecture 7.1 for \( \alpha' \). The inequality \( \beta(U) = \beta'(U) \) is similar. \( \square \)

We are far from knowing the multiplicativity of \( \alpha \), as we cannot even compute \( \alpha(\{0,1\}^d) \). We do know multiplicativity of \( \beta \).

**Theorem 7.4 (Multiplicativity of \( \beta \)).** Let \( G = G_1 \times G_2, V_1 \subset G_1, V_2 \subset G_2, U = V_1 \times V_2 \). We have
\[
\beta_p(U) = \beta_p(V_1)\beta_p(V_2).
\]
This will follow from supermultiplicativity, which we shall establish in a more general setting.

**Theorem 7.5 (\( \beta \) along fibers).** Let \( G \) be a group, \( H \) its subgroup, \( G' = G/H \) the factor group, \( \varphi : G \to G' \) the natural homomorphism, \( U \subset G, V = \varphi(U) \). We have
\[
\beta_p(U) \geq \beta_p(V) \min_{x \in V} \beta_p(U \cap \varphi^{-1}(x)).
\]
If \( H \) is a direct factor, this can be reformulated as follows.

**Corollary 7.6.** Let \( G = G_1 \times G_2, V \subset G_1, \) and for each \( x \in V \) given a set \( W_x \subset G_2 \).

Put \( U = \bigcup_{x \in V} \{x\} \times W_x \).

We have
\[
\beta_p(U) \geq \beta_p(V) \min_{x \in V} \beta_p(W_x).
\]

Theorem 7.5 (and thus Theorem 7.4 and Corollary 7.6) will be proved in a yet more general form in Section 10. It turns out that a functional analog of \( \beta \) that we introduce shortly, provides greater flexibility for carrying out an induction argument.

**Part II: functions**

8. **Functional tripling**

We shall consider nonnegative-valued functions in the space \( \ell^1(G) \). A set \( A \) naturally corresponds to the function \( 1_A \).

**Definition 8.1.** The max-convolution of the functions \( f, g \) is
\[
(f \boxplus g)(x) = \max_t f(t)g(x - t).
\]
This generalizes the notion of sumset. For the indicator functions $1_A, 1_B$ of sets $A, B$ we have

$$1_A \bar{+} 1_B = 1_{A+B}.$$  

One can replace the notion of cardinality of a set with the $\ell^1$ norm of a function. However, we have a more robust notion.

**Definition 8.2.** The level sets of a function $f$ are the sets

$$F(t) = \{ x \in G : f(x) \geq t \}.$$  

The distribution function of $f$ is the function $F : \mathbb{R}^+ \rightarrow \mathbb{Z}$ given by

$$F(t) = |F(t)|.$$  

Note that this is different from the definition used in probability theory.

**Definition 8.3.** Let $f, g$ be functions with distribution functions $F, G$. If $F = G$, we call them identically distributed and write $f \sim g$.

**Definition 8.4.** The functional triplings of a function $f$ are the quantities

$$\gamma(f) = \inf_{g,h} \| f \bar{*} g \bar{*} h \|_1,$$

the unrestricted tripling;

$$\gamma_p(f) = \inf_{g,h} \| f \bar{*} g \bar{*} h \|_1 \| g \|_p \| h \|_q,$$

its asymmetric variant, where $1/p + 1/q = 1$;

$$\gamma'(f) = \inf_{g \sim h} \| f \bar{*} g \bar{*} h \|_1,$$

the isometric tripling;

$$\gamma''(f) = \inf_{g} \| f \bar{*} g \bar{*} g \|_1 \| g \|_2^2,$$

the isomeric tripling.

**Conjecture 8.5.**

$$\gamma = \gamma' = \gamma''.$$

Tripling of sets can be expressed via functional tripling.

**Theorem 8.6 (Function and Set analog of $\beta$ are the same).** Let $U$ be any finite set in a commutative group. We have

$$\beta_p(U) = \gamma_p(1_U), \ \beta'(U) = \gamma'(1_U), \ \beta'(U) = \gamma''(1_U).$$  

**Proof.** We prove only $\beta_p(U) = \gamma_p(1_U)$, as the other equalities follow similarly (in fact the definitions of $\gamma', \gamma''$ are designed just for this). We have

$$\frac{|A + B + U|}{|A|^p|B|^q} = \frac{\| 1_U \bar{*} 1_A \bar{*} 1_B \|_1}{\| 1_A \|_p \| 1_B \|_q},$$

and the inequality $\gamma_p(1_U) \leq \beta_p(U)$ follows from taking an infimum over $A$ and $B$.

To prove the reverse inequality, we need a lemma, which is a multiplicative analog of Prékopa-Leindler, Theorem 2.13.
Lemma 8.7 (Multiplicative Prékopa-Leindler). Let $F, G, H$ be measurable functions $\mathbb{R}_+ \rightarrow [0, 1]$ and $1 < p, q < \infty$ are Hölder conjugates, that is

$$\frac{1}{p} + \frac{1}{q} = 1.$$ 

Assume that for any $u, v \in \mathbb{R}_+$

$$H(uv) \geq F(u)G(v).$$

Then

$$\|H\|_1 \geq \left( \int_0^1 F^p(t^{1/p})dt \right)^{1/p} \left( \int_0^1 G^q(t^{1/q})dt \right)^{1/q}$$

Proof. Define

$$h(x) := H(e^{-x})e^{-x}$$

and further

$$f(x) := F^p(e^{-x/p})e^{-x}$$

(8.1)

$$g(x) := G^q(e^{-x/q})e^{-x}.\tag{8.2}$$

We then have that for any $x, y > 0$

$$h(x/p + y/q) \geq f^{1/p}(x)g^{1/q}(y),$$

so by the Prékopa-Leindler inequality, Theorem 2.13

$$\|h\|_1 \geq \|f\|_1^{1/p}\|g\|_1^{1/q}.$$ 

The claim follows after the change of variables $t = e^{-x}$. \qed

We want to prove that for any non-negative functions $g, h$

$$\|1_V \mathcal{F} g \mathcal{F} h\|_1 \geq \beta(V)\|g\|_p \|h\|_q.$$ 

After rescaling, we may assume $\max g = \max h = 1$. Let

$$S(t) := \{z : 1_V \mathcal{F} g \mathcal{F} h(z) \geq t\}.$$ 

Further define the distribution functions

$$G(t) := \{z : g(z) \geq t\}$$

and

$$H(t) := \{z : h(z) \geq t\}.$$ 

For any $u, v$ then have the inclusion

$$G(u) + H(v) + V \subset S(uv),$$

so

$$|S(uv)| \geq \beta_p(V)|G(u)|^{1/p}|H(v)|^{1/q}.$$ 

It follows from Lemma 8.7 that

$$\|1_V \mathcal{F} g \mathcal{F} h\|_1 \geq \beta_p(V) \left( \int_0^1 G(t^{1/p})dt \right)^{1/p} \left( \int_0^1 H(t^{1/q})dt \right)^{1/q}.$$ 

The result now follows from the layer-cake principle of the form

$$\int F(t^{1/p})dt = \int f(t)^p dt.$$ 

\qed
9. The independence problem

The independence problem arises as it did for sets.

For this section we change the notations to $\gamma(U, G)$ etc. to indicate the ambient group.

**Theorem 9.1** (Ambient group does not change $\gamma$). Let $G$ be a group, $G'$ its subgroup, $f \in \ell^1(G')$. We have

$$\gamma_p(f, G) = \gamma_p(f, G').$$

**Proof.** This follows from Theorem 8.6 and Theorem 1.2. \qed

**Conjecture 9.2** (Functional independence hypothesis). Let $G$ be a group, $G'$ its subgroup, $f \in \ell^1(G')$ and let $\vartheta$ be any of the functionals $\gamma', \gamma''$. We have

$$\vartheta(f, G) = \vartheta(f, G').$$

10. Direct product

**Theorem 10.1** (Multiplicativity). Let $G = G_1 \times G_2$, $f_1 \in \ell^1(G_1)$, $f_2 \in \ell^1(G_2)$, and define $f \in \ell^1(G)$ by $f(x, y) = f_1(x)f_2(y)$. We have

$$\gamma_p(f) = \gamma_p(f_1)\gamma_p(f_2),$$

$$\gamma'(f) \leq \gamma'(f_1)\gamma'(f_2),$$

$$\gamma''(f) \leq \gamma''(f_1)\gamma''(f_2).$$

**Proof.** The $\leq$ inequalities all follow from the fact that (with $g_i, h_i$ defined similarly to $f_i$)

$$f \triangleright g \triangleright h(x, y) \leq f_1 \triangleright g_1 \triangleright h_1(x)f_2 \triangleright g_2 \triangleright h_2(y)$$

for any $x \in G_1$ and $y \in G_2$.

The reverse inequality for $\gamma_p$ follows from a much more general Theorem 10.2 (and Theorem 10.3) towards which we immediately proceed. \qed

**Theorem 10.2** (Tensorization). Let $G$ be a group, $H$ a subgroup, $G' = G/H$ the factor group, $\varphi : G \rightarrow G'$ the natural homomorphism, $f \in \ell^1(G)$. Define $f_\varphi \in \ell^1(G')$ by

$$f_\varphi(x) := \gamma_p(f|_{\varphi^{-1}(x)}).$$

We have $\gamma_p(f) \geq \gamma_p(f_\varphi)$.

**Proof.** Let $g, h \in \ell(G)$ be non-negative. We have

$$||f \triangleright g \triangleright h||_1 = \sum_{x \in G} \max_{x_1 + x_2 + x_3 = z} f(x_1)g(x_2)h(x_3)$$

$$= \sum_{z_1 \in G'} \sum_{z \in z_1 + H} \max_{w_1 \in z_1, w_2 \in z_2, w_3 \in z_3} \max_{x_1 + x_2 + x_3 = z} f(x_1)g(x_2)h(x_3)$$

$$\geq \sum_{z_1 \in G'} \sum_{w_1, w_2, w_3 \in G'} \sum_{z \in z_1 + H} \max_{x_1 + x_2 + x_3 \in H} f(x_1)g(x_2)h(x_3)$$

(10.1)

Define the functions $g', h'$ on $G'$ as follows

$$g'(w_2) := ||g|_{\varphi^{-1}(w_2)}||_p, h'(w_3) := ||h|_{\varphi^{-1}(w_3)}||_q.$$
One can further estimate (10.1)
\[ \geq \sum_{z_1 \in G} \max_{w_1, w_2, w_3 \in G} f_{\varphi}(w_1)g'(w_2)h'(w_3) \]
\[ \geq \gamma_p(f_\varphi)||g'||_p||h'||_q \]
The last inequality follows from the observation that
\[ ||g'||_p = ||g||_p, \quad ||h'||_q = ||h||_q. \]

We can specialize Theorem 10.2 to cartesian products.

**Theorem 10.3.** Let \( G = G_1 \times G_2 \), \( f \) a function on \( G \). For \( x \in G_1 \), define \( f_x(y) = f(x, y) \), functions on \( G_2 \). Let \( g(x) = \gamma(f_x) \), a function on \( G_1 \). We have \( \gamma_p(f) \geq \gamma_p(g) \).

**Proof.** We let \( \varphi : G_1 \times G_2 \to G_1 \) by projection. Then
\[ f_{\varphi}(x) = \gamma(f_x), \]
and so the result follows from Theorem 10.2. \( \square \)

We are now ready to prove Theorem 7.5

**Theorem 7.5.** Let \( U \) be as in the statement and \( f = 1_U = : U \). Then, by Theorem 8.6 for \( x \in V \)
\[ f_{\varphi}(x) := \gamma_p(f|_{\varphi^{-1}(x)}) = \beta_p(U \cap \varphi^{-1}(x)). \]
In particular, we have the point-wise bound
\[ f_{\varphi}(x) \geq 1_V(x) \min_{t \in V} \beta_p(U \cap \varphi^{-1}(t)), \]
so again by Theorem 8.6 and linearity
\[ \gamma_p(f_{\varphi}) \geq \beta_p(V) \min_{t \in V} \beta_p(U \cap \varphi^{-1}(t)). \]
The result now follows from Theorem 10.2 as
\[ \beta_p(U) = \gamma_p(f) \geq \gamma_p(f_{\varphi}) \geq \beta_p(V) \min_{x \in V} \beta_p(U \cap \varphi^{-1}(x)). \]
\( \square \)

11. Functional tripling for functions supported on quasicubes

The goal of this section is to prove Theorem 2.7. The basic strategy is to use tensorization to reduce to a two-point inequality. We let \( U \) be a \( d \) dimensional quasi-cube, defined in Definition 2.5. Thus \( U \) is \( d \) dimensional as thus we may assume
\[ U \subset H' \times \mathbb{Z}^d, \]
where \( H' \) is a torsion subgroup. We first show we may assume \( H' = \{0\} \). Let \( \pi \) be the projection to \( \mathbb{Z}^d \). Then by induction, it follows that \( |\pi(U)| = |U| \). Thus for \( V \subset U \), to prove Theorem 2.7
\[ \beta(\pi(V)) \geq |V|. \]
By Theorem 4.2, we may assume
\[ V \subset U \subset \mathbb{Z}^d. \]
Central to our study will be the following.
Theorem 11.1 (γ for two-point functions). For 0 ≤ δ ≤ 1,
\[ f_\delta := 1_{\{0\}} + \delta 1_{\{1\}}. \]
Then
\[ \gamma(f_\delta) = \delta + 1, \]
and more generally,
\[ \gamma_p(f_\delta) \geq \frac{p^{1/p} q^{1/q}}{2} (1 + \delta). \]

We remark that the stronger
\[ \gamma_p(f_\delta) \geq (\delta^c + 1)^{1/c}, \quad 2^{1/c} = p^{1/p} q^{1/q}, \]
is probably true, though we do not require it (see this mathoverflow post [Sha19]). Such a result would be useful for quasi-cubes that are asymmetrical in size. We also remark that Prékopa [Pré71, Equation 2.4] proved Theorem 11.1 in the special case \( p = q = 2 \) and \( \delta = 1 \) and his proof extends to the \( \delta = 0 \) case.

We now present an important family of examples. First, they are a natural guess for minimizers of \( \gamma_p(f_\delta) \) and indeed show that Theorem 11.1 is best possible. Secondly, in the proof of Theorem 11.1 below, we show that to bound \( \gamma_p(f_\delta) \) from below it is enough to consider \( g \) and \( h \), from Definition 8.4, from the following.

Example 11.2. Fix 0 < δ < 1. Let \( g = (1, \delta, \ldots, \delta^r) \) and \( h = (1, \delta, \ldots, \delta^s) \). Then
\[ \|f_\delta \overline{g} \overline{h}\|_1 = \sum_{j=0}^{r+s+1} \delta^j = \frac{1 - \delta^{r+s+2}}{1 - \delta}, \]
while
\[ \|g\|_p^p = \frac{1 - \delta^{p(r+1)}}{1 - \delta^p}, \]
and
\[ \|h\|_q^q = \frac{1 - \delta^{q(s+1)}}{1 - \delta^q}. \]

Note that
\[ (11.1) \quad \frac{1 - \delta^{r+s+2}}{(1 - \delta^{p(r+1)})^{1/p}(1 - \delta^{q(s+1)})^{1/q}} \geq 1. \]
Indeed, this follows from the inequality
\[ (1 - xy) \geq (1 - x^p)^{1/p}(1 - y^q)^{1/q}, \quad 0 \leq x, y \leq 1, \]
which is an application of Hölder’s inequality applied to the vectors
\[ (x^n)_{n \in \mathbb{Z}_{\geq 0}}, \quad (y^n)_{n \in \mathbb{Z}_{\geq 0}}. \]
Thus (11.1) is minimized by allowing \( r, s \to \infty \) and so
\[ \frac{\|f_\delta \overline{g} \overline{h}\|_1}{\|g\|_p \|h\|_q} \geq \frac{(1 - \delta^p)^{1/p}(1 - \delta^q)^{1/q}}{1 - \delta}. \]
In the most important case, that is \( p = q = 2 \), we have
\[ \frac{\|f_\delta \overline{g} \overline{h}\|_1}{\|g\|_2 \|h\|_2} \geq 1 + \delta, \]
while the more general case is a bit harder.
Lemma 11.3. [Minimizer for $\gamma_p$] Let $0 < \delta < 1$ and $$g = h = (1, \delta, \delta^2, \ldots).$$ Then we have $$\frac{\|f \star g \star h\|_1}{\|g\|_p \cdot \|h\|_q} \geq \frac{p^{1/p} q^{1/q}}{2} (1 + \delta).$$

Proof. Similar to the $p = q = 2$ case above it suffices to show that $$\frac{(1 - \delta^p)^{1/p} (1 - \delta^q)^{1/q}}{1 - \delta} \geq \frac{p^{1/p} q^{1/q}}{2} (1 + \delta)$$ or $$\frac{(1 - \delta^p)^{1/p} (1 - \delta^q)^{1/q}}{1 - \delta} \geq \frac{p^{1/p} q^{1/q}}{2} (1 - \delta^q).$$ This follows upon applying Hölder’s inequality:

$$\int_{\delta}^{1} s^2 \frac{ds}{s} \leq \left( \int_{\delta}^{1} s^p \frac{ds}{s} \right)^{1/p} \left( \int_{\delta}^{1} s^q \frac{ds}{s} \right)^{1/q}. $$

\[ \square \]

Proof of Theorem 2.7 and Theorem 2.11. We first show how Theorem 11.1 implies Theorem 2.7. Thus we assume $p = q = 2$. By the discussion at the beginning of the current section we may assume that $V \subset \mathbb{Z}^d$. By Theorem 4.2 we can further assume that in fact $V \subset \mathbb{Q}^d$. Since $\beta$ is invariant under bijective linear transformations of $\mathbb{Q}^d$, after a suitable translation and choosing a basis $\{e_i\}$ for the ambient group $\mathbb{Q}^d$ (now viewed as a linear space) one can WLOG write

$$V = 0 \oplus V_0 \cup e_1 \oplus V_1,$$

where $V_0$ and $V_1$ are $d - 1$ dimensional quasi-cubes.

Now, we again use the independence of the ambient group (Theorem 4.2) to reduce the ambient group to the one generated by $V$, so that now $V \subset G := \mathbb{Z}e_1 \times \mathbb{Z}^{d-1}$.

Let $A, B \subset \mathbb{Z}^d$ and write

$$A = \bigcup_i i e_1 \oplus A_i, \quad B = \bigcup_j j e_1 \oplus B_j.$$ 

We claim that $\gamma(1_V) = |V|$ and in particular

$$(11.2) \quad |A + B + V| \geq ||f \star g \star h||_1,$$

where $$f = |V_0| 1_0 + |V_1| 1_1, \quad g(i) = |A_i|^{1/2}, \quad h(j) = |B_j|^{1/2}.$$ 

We induct on the dimension on $V$. The base case follows directly from Theorem 11.1 and linearity of $\gamma$.

We let $\pi_1$ be projection onto the first coordinate and

$$X_k = \pi_1^{-1}(k) \cap (A + B + V).$$
Then, \(X_k\) contains all the fiber sumsets as long as the first coordinate equals \(k\), so
\[
|X_k| = \max \{ \max_{i+j=k} |A_i + B_j + V_0|, \max_{i+j=k-1} |A_i + B_j + V_1| \} \\
\geq \max \{ \max_{i+j=k} \beta(V_0)|A_i|^{1/2}B_j|^{1/2}, \max_{i+j=k-1} \beta(V_1)|A_i|^{1/2}B_j|^{1/2} \} \\
= \max \{ \max_{i+j=k} \gamma(1_{V_i})|A_i|^{1/2}B_j|^{1/2}, \max_{i+j=k-1} \gamma(1_{V_1})|A_i|^{1/2}B_j|^{1/2} \} \\
= \max \{ \max_{i+j=k} |V_0||A_i|^{1/2}B_j|^{1/2}, \max_{i+j=k-1} |V_1||A_i|^{1/2}B_j|^{1/2} \} \\
= f \overline{f} g \overline{f} h(k).
\]

Summing over \(k\) gives (11.2). By Theorem 11.1 we have
\[
|A + B + V| \geq \|f \overline{f} g \overline{f} h\|_1 \geq (|V_1| + |V_2|)\|f\|_2\|g\|_2 = |V| |A|^{1/2} |B|^{1/2},
\]
which implies Theorem 2.7.

We now handle the case of general \(p\). Everything proceeds the same as in the \(p = 2\) case, except the induction claim is
\[
\gamma_p(1_V) \geq \frac{|V|^d|p|d!}{2^d}.
\]

Theorem 2.11 now follows from Theorem 8.6.

We now proceed to the proof of Theorem 11.1. We first need the following lemma.

**Lemma 11.4 (γ and permutations).** Let \(f, g, h : \mathbb{Z} \to \mathbb{R}\) be non-negative functions with finite support. Let \(\sigma, \tau, \rho\) be permutations of the support of \(f, g, h\), respectively. Set
\[
f_\sigma(x) := f \circ \sigma(x),
\]
and similarly for \(g\) and \(h\). Then
\[
\|f_\sigma \overline{f} g_\tau \overline{f} h_\rho\|_1,
\]
is minimized for a choice of permutations that makes each function non-increasing.

**Proof.** We may suppose, after translation, that the smallest element of the support is zero for all three functions. Put \(F := f \overline{f} g \overline{f} h\) and let \(\sigma, \tau, \rho\) be some permutations such that \(f_\sigma, g_\tau, h_\rho\) are non-increasing. Note that \(G := f_\sigma \overline{f} g_\tau \overline{f} h_\rho\) is then also non-increasing. Let \(s\) be a sufficiently large number and order the sequence \(F(0), \ldots, F(s)\) (which will end with zeroes) via
\[
(11.3) \quad F_0 \geq \cdots \geq F_s.
\]
We claim that for \(0 \leq v \leq s\)
\[
f_\sigma \overline{f} g_\tau \overline{f} h_\rho(v) = G(v) \leq F_v,
\]
and the result follows from this claim. Let \(m, n, r\) be such that \(m + n + r = v\) and
\[
f_\sigma(m)g_\tau(n)h_\rho(r) = G(v).
\]
It follows by the choice of $\sigma, \tau, \rho$, that for any $i \leq m$, $j \leq n$, $k \leq r$

$$G(v) = f(\sigma(i))g(\tau(j))h(\rho(k)) \leq F(\sigma(i) + \tau(j) + \rho(k))$$

It follows that for any

$$t \in \{\sigma(0), \ldots, \sigma(m)\} + \{\tau(0), \ldots, \tau(n)\} + \{\rho(0), \ldots, \rho(r)\}$$

holds

$$G(v) \leq F(t).$$

But the sumset on the RHS of (11.4) is of size at least $m + n + r + 1$, by the Cauchy-Davenport inequality. Thus, there are at least $v + 1$ values in the sequence (11.3) that are no less than $G(v)$, and hence

$$G(v) \leq F_v.$$ 

\[\square\]

**Proof of Theorem 11.1.** We aim to show that for non-negative valued $g$ and $h$ in $\ell_1(\mathbb{Z})$

$$\|f_{\delta} \overline{g} \overline{h}\|_1 \geq c_{\delta} = \frac{(1 - \delta^p)^{1/p}(1 - \delta^q)^{1/q}}{1 - \delta},$$

We remind the reader that $c_{\delta}$ is the infimum of (11.5) over all $g, h$ of the form

$$g = (1, \delta, \ldots, \delta^r), \quad h = (1, \delta, \ldots, \delta^s),$$

as shown in Example 11.2.

We suppose there is a $g, h \in \ell_1(\mathbb{Z})$ such that (11.5) is smaller than $c_{\delta}$. By continuity, we may suppose both $g$ and $h$ have finite support. By Lemma 11.4, we may permute $g, h$ so they are both non-increasing. After translation of the supports, we suppose

$$g = (g_0, \ldots, g_r), \quad h = (h_0, \ldots, h_s).$$

We further assume that $r + s$ is minimally chosen. Thus

$$\|f_{\delta} \overline{u} \overline{v}\|_1 \geq c_{\delta},$$

for any $u$ and $v$ satisfying

$$|\text{supp}(u)| + |\text{supp}(v)| < r + s + 2.$$

By compactness, there exists $g, h$ which minimize (11.5) subject to $\text{supp}(g) \subseteq \{0, \ldots, r\}$, $\text{supp}(h) \subseteq \{0, \ldots, s\}$, and

$$\|g\|_p = 1, \quad \|h\|_q = 1.$$

Because the value of (11.5) doesn’t change by multiplying $g$ and $h$ by constant, this is also a minimum over all $g$ and $h$ where $\text{supp}(g) \subseteq \{0, \ldots, r\}$ and $\text{supp}(h) \subseteq \{0, \ldots, s\}$

Set

$$g(x) = f_{\delta} \overline{g} \overline{h}(x).$$

Let

$$Q_1 \subset \{0, \ldots, r\}, \quad Q_2 \subset \{0, \ldots, s\}.$$
We let $R(Q_1)$ be the set of all indices $n \in \{0, \ldots, r + s + 1\}$ such that if

$$p_n = f_i g_j h_k, \quad (i + j + k = n),$$

then $j \in Q_1$, and similarly for $Q_2$. We now analyze what happens when we replace $g$ with $g_i$ which we get by multiplying all $g(i)$ by $(1 - t)$ where $i \in Q_1$. $(t$ is a small enough positive real number.)

In $f_\delta g \overline{g} h$, the values corresponding to $R(Q_1)$ will be multiplied by $(1 - t)$, the other values will be the same as in $f_\delta g \overline{g} h$.

$$r(t) := \frac{||f_\delta g \overline{g} h||_1}{||g||_p ||h||_q}.$$ 

$r'(0)$ is the right-hand derivative of $r(t)$ at 0. By minimality, $r'(0) \geq 0$.

The right-hand derivative of $||f \overline{g} g \overline{h}||_1$ at 0 is

$$-\sum_{y \in R(Q_1)} p(y)$$

and the right-hand derivative of $||g||_p$ is

$$-\frac{1}{p} \frac{1}{||g||_p^{p+1}} p(1 - t)^{p-1} (-1) \sum_{x \in Q_1} g(x)^p$$

which is equal to

$$\sum_{x \in Q_1} g(x)^p$$

at 0.

So

$$0 \leq r'(0) = \frac{||p||_1}{||g||_p^{p+1} ||h||_q} - \sum_{y \in R(Q_1)} p(y)$$

By symmetry we get a similar inequality for any $Q_2 \subset \{0, \ldots, s\}$, so by reframing the inequalities

$$(11.8) \quad ||p||_1^{1/p} \geq \frac{||g||_p \left( \sum_{y \in R(Q_1)} p(y) \right)^{1/p}}{\left( \sum_{x \in Q_1} g(x)^p \right)^{1/p}}, \quad ||p||_1^{1/q} \geq \frac{||h||_q \left( \sum_{y \in R(Q_2)} p(y) \right)^{1/q}}{\left( \sum_{x \in Q_2} h(x)^p \right)^{1/p}}$$

We now define new functions,

$$a(i) = \delta^{-i} g(i), \quad b(j) = \delta^{-j} h(j).$$

We set

$$Q_1 = \{ i : a(i) = \max a \}, \quad Q_2 = \{ j : b(j) = \max b \}.$$ 

and set

$$u(i) = g(i) 1_{Q_1}(i), \quad v(j) = h(j) 1_{Q_2}(j).$$

$$R(Q_1) \supseteq \text{supp}(f_\delta g \overline{u} \overline{v}), \quad R(Q_2) \supseteq \text{supp}(f_\delta g \overline{u} \overline{v})$$

So $\sum_{y \in R(Q)} p(y) \geq ||f_\delta g \overline{u} \overline{v}||_1$ is true for both $Q_1$ and $Q_2$.

Combining it with (11.8), we get
\begin{align*}
(11.9) \quad \|p\|_1^{1/p} & \geq \frac{\|g\|_p \| f_\delta \ast (u \ast v)\|_1^{1/p}}{\|u\|_p}, \quad \|p\|_1^{1/q} \geq \frac{\|h\|_q \| f_\delta \ast (u \ast v)\|_1^{1/q}}{\|v\|_q} \\
\text{Multiplying the two inequalities in (11.9), we get} & \\
\frac{\|f_\delta \ast g \ast h\|}{\|g\|_p \|h\|_q} & \geq \frac{\|f_\delta \ast u \ast v\|}{\|u\|_p \|v\|_q} \\
\text{If either } a \text{ or } b \text{ is not constant, then } u \text{ or } v \text{ has a value of 0 at some point. Then by Lemma 11.4 we can rearrange it to a non-increasing order, with making} & \\
\frac{\|f_\delta \ast u \ast v\|}{\|u\|_p \|v\|_q} \text{ smaller or equal after the rearrangement.} \\
\text{Now } |\text{supp}(u)| + |\text{supp}(v)| < |\text{supp}(g)| + |\text{supp}(h)|, \text{ so because we started with a counterexample with minimal supports,} & \\
\frac{\|f_\delta \ast u \ast v\|}{\|u\|_p \|v\|_q} & \geq c_\delta \\
\text{This is a contradiction, because we assumed that} & \\
\frac{\|f_\delta \ast g \ast h\|}{\|g\|_p \|h\|_q} & < c_\delta \\
\text{So } a \text{ and } b \text{ must both be constant, but then (11.5) can’t be smaller than } c_\delta, \text{ as proved in Example 11.2. Thus the ratio in (11.5) is at least } c_\delta. \text{ By Lemma 11.3} & \\
\frac{c_\delta}{2} & \geq p^{1/p} q^{1/q} \frac{(1 + \delta)}{2}. \\
\end{align*}
