Abstract

In the present research work, the solid-liquid reaction was successfully carried out in the new synthesized multi-site phase-transfer catalyst, namely i.e., 1,3,5-tri-butyl-1,3,5-tri-methyl-1,3,5-triazinane-1,3,5-trium trichloride(MPTC), and sonication (40 kHz, 300 W) to produce the desired product namely 1-(4-nitrophenyl) pyrrole from pyrrole and 4-nitrochlorobenzene. The selectivity of N-arylation product was obtained under sonication and MPTC. The combination of ultrasound and MPTC resulted in better efficacy as compared to the individual operations. The apparent reaction rate is greatly enhanced and observed to obey the pseudo-first order kinetics. The k app value increases with increasing kinetic parameters that is the amount of [MPTC], [substrate], ultrasonication, stirring speed, temperature, etc.

Keywords: Sonochemistry; Pyrrole; Interfacial reaction; Kinetics; MPTC; 1-Chloro-4-Nitrobenzene

Introduction

As the chemical reactants reside in immiscible phases, phase-transfer catalysts have the ability to carry out the heterogeneous reactions by one of the reactants penetrating from its normal phase (generally aqueous phase) to the organic phase where the reaction takes place, which gives a high conversion and selectivity for the desired product under mild reaction conditions [1]. The quaternary onium salts as an effective catalysts for enhancing the two-phase reaction, this methodology occupies an unique niche in organic synthesis and it is a commercially matured discipline with over six hundred applications [2-7] covering a wide spectrum of industries such as pharmaceuticals, agrochemicals, dyes, perfumes, flavours, specialty polymers, pollution control, etc. As the application of phase-transfer catalysts (PTC) grow, much effort was placed on the development of phase - transfer catalysts with higher catalytic efficiency. To this end, researchers have developed "multi-site" phase-transfer catalysts (MPTC) for much higher activity with higher catalytic efficiency. To this end, researchers have developed “multi-site” phase-transfer catalysts (MPTC) for much higher activity than normal phase-transfer catalysts. Recently, the catalytic behaviour of multi-site phase-transfer catalysts have been attracted much attention, due to the fact that multiple molecules of the aqueous reactant can be carried into the organic phase once a reaction cycle, thus the catalytic efficiency is enhanced [8-12].

Currently, anew analytical and process experimental techniques which are environmental benign techniques viz., ultrasound and microwave irradiation have become immensely popular in promoting various organic reactions [13-17]. Ultrasound irradiation is a transmission of a sound wave through a medium and is regarded as a form of energy enhances the rate of the reaction due to mass transfer and effective mixing [18-20].

The effect of ultrasonic energies in organic syntheses (homogeneous and heterogeneous reactions) has been boosted in recent years [21-27]. Sonication of multiphase systems accelerates the reaction by ensuring a better contact between the different phases [28,29]. Further, ultrasound irradiations also increase the reaction rate and avoid the use of high reaction temperatures [30]. These days this environmental benign technology is combined with phase-transfer catalysts (PTC) with primary objective of optimizing reaction conditions [31-33].

Our interest was entered on first time evaluating the influence of ultrasound in association with multi-site phase-transfer catalyst (MPTC) on the synthesis of 1-(4-nitrophenyl) pyrrole from pyrrole with 1-chloro-4-nitrobenzene (CNB) under heterogeneous condition. Since, the kinetic study of nitroarylation of pyrrole using 1-chloro-4-nitrobenzene under controlled MPTC reaction conditions will be interesting and challenging, we followed the kinetic studying a newly synthesized multi-site phase-transfer catalyst (MPTC) viz., 1,3,5-tri-benzyl-1,3,5-triethyl-1,3,5-triazinane-1,3,5-trium trichloride, as a catalyst under ultrasonic condition (40 kHz; 300 W). Further,
to the best of our knowledge, there is no literature reports regarding nitroarylation of pyrrole under MPTC-ultrasonic irradiation condition.

**Experimental**

**Chemicals**

The reagents pyrrole, 1-chloro-4-nitrobenzene (CNB), sodium hydroxide, benzene, toluene, chlorobenzene, biphenyl and other reagents are synthesis guaranteed grade (GR) chemicals and were used without further treatments.

**Instrumentation**

FT-IR Spectra were recorded on a Brucker- Tensor 27 FT-IR spectrophotometer. ¹H NMR and ¹³C spectra were recorded on a Bruker 300 MHz and 75 MHz respective using TMS as an internal standard. Gas chromatography was carried out using a GC-Varian 3700 model Ultrasonic water bath, Equiron, Media Instrument Manufacturing Company, Chennai, India. The ultrasonic generator was a thermostatic bath equipped with dual frequencies (28/40 kHz) and electric power 300 W. Both ultrasounds separately produced through a flat transducer supported at the centre of the ultrasonic cleaning bath 2 cm above from the position of the transducer to get the maximum ultrasound energy.

**Ultrasonic process equipment**

Ultrasonic energy is transmitted to the process vessel through the liquid medium, usually water in the tank. For safety purpose, the sonochemical reactor consisted of two layers stainless steel body. The sonochemical reactor configuration used in the present work is basically an ultrasonic bath. The internal dimension of the ultrasonic cleaner tank is 48 cm × 28 cm × 20 cm with liquid holding capacity of 5 litres. Two types of frequencies of ultrasound were used in these experiments, which are 28 kHz and 40 kHz with each output as 300 W. Both ultrasound separately produces through a flat transducer mounted at the bottom of the sonicator. The reactor was a 250 mL three-necked Pyrex round-bottom flask. This reaction vessel was supported at the bottom of the sonicator. The reactor was a 250 mL three-necked Pyrex round-bottom flask. This reaction vessel was supported at the centre of the ultrasonic cleaning bath 2 cm above from the position of the transducer to get the maximum ultrasound energy. All the experimental parameters were done at 40 kHz with output power of 300 W.

**Synthesis of 1,3,5-triethyl-1,3,5-triazinane**

A mixture of 8.7 g of ethylamine, 40 g of Para paraldehyde and was placed in a 250 mL three-necked round bottomed Pyrex flask. The reaction was carried out at 30°C for 4 hours and was gently refluxed in the nitrogen atmosphere. The solvent was then completely removed under vacuum and we get, i.e., 1,3,5-triethyl-1,3,5-triazinane (Scheme 1). The white liquid was stored in a CaCl₂ desiccator. Yield: 92%; ¹H NMR (300 MHz, CDCl₃): δ 1.054-1.102 (t, 9H-CH₂), 2.449-2.522 (q, 6H-CH₂), 3.432 (s, 6H-CH₂). ¹³C NMR (75 MHz, CDCl₃): δ 12.62 (C₂H₂), 46.50 (C₂H₂), 73.72 (N=C=H). MS (EI, 70 Ev, %): m/z 171.17; Elemental analysis Calc.: C, 65.19%; H, 7.28%; N, 7.02%; Found, C, 65.39%; H, 7.68%; N, 7.62%.

**Synthesis of MPTC**

A mixture of 8.7 g (50.7 mmol) of 1,3,5-triethyl-1,3,5-triazine, 25 mL of benzyl chloride, and 75 mL of ethanol was placed in a 250 mL three-necked round bottomed Pyrex flask. The reaction was carried out at 40°C for 24 hours and was gently refluxed in the nitrogen atmosphere. The solvent was then completely removed under vacuum and onium salt, i.e., 1,3,5-tribenzyl-1,3,5-triethyl-1,3,5-triazinane-1,3,5-trium trichloride (MPTC, Scheme 2) was washed with n-hexane (3 × 20 mL). The white solid MPTC was stored in CaCl₂ desiccators.

**Synthesis of 1-(4-nitrophenyl) pyrrole under mechanical stirring**

To the mixture of NaOH (20 g) in water (15 mL) and the newly synthesized MPTC (0.3 g), pyrrole (1.0 g, 0.0152 mol) was added under overhead stirring to generate the pyrrole anion. Then 1-chloro-4-nitrobenzene (2.0 g, 0.0127 mol) in chlorobenzene (40 mL) was added slowly. The reaction mixture was heated at 60°C for 6 hours with vigorous stirring. The crude product was isolated by simple extraction with diethyl ether (3 × 25 mL). The organic layer was collected and the solvent was evaporated under reduced pressure. The crude product was chromatography (SiO₂) employing hexane: ethyl acetate (9:1) as an eluent to obtain a pure monodervative. The identity of the product was confirmed by ¹H NMR and ¹³C NMR spectra of the product. m.p. 182°C; Yield: 94%; ¹H NMR (300 MHz, CDCl₃): δ 1.403-1.451 (t, 9H-CH₂), 2.960-3.024 (q, 6H-CH₂), 4.140 (s, 6H-Ar-CH₃), 5.203 (s, 6H, Ar-CH₃), 7.345-7.666 (m, 15H, Ar-H); ¹³C NMR (75 MHz, CDCl₃): δ 50.40 (Ar-CH₃), 66.18 (N=C=H), 41.92 (CH₂-CH₃), 11.22 (CH₂-CH₃), 128.98, 129.41, 130.51, 131.36 (Ar-C). Elemental analysis Calc.: C, 65.19%; H, 7.28%; N, 7.02%; Found, C, 65.39%; H, 7.68%; N, 7.62%.

**Reaction mechanism and kinetic model**

For synthesizing 1-(4-nitrophenyl) pyrrole compound, the overall reaction of pyrrole and 1-chloro-4-nitrobenzene (CNB) was catalyzed by the newly prepared MPTC (Q‘Cl) in the aqueous alkaline (NaOH)
bi-phase medium and is represented in Scheme 2. The reaction is carried out under MPTC assisted ultrasonic irradiation condition (40 kHz, 300 W) under pseudo first-order condition. In the current investigation the kinetics was followed in the presence of an excess amount of pyrrole and by fixing 1-chloro-4-nitrobenzene as limiting agent. The main reason for investigating this reaction is, the effect of low frequency ultrasound irradiation (40 kHz, 300 W) along with agitation speed (300 rpm) to find out the effect of change of \( k_{app} \) value of this system.

**Definition**

The conversion (X) of 1-chloro-4-nitrobenzene (CNB) is defines as follows:

\[
X = 1 - \frac{[\text{CNB}]_0}{[\text{CNB}]} \quad (1)
\]

Where \([\text{CNB}]_0\) and \([\text{CNB}]\) represent the concentration of 1-chloro-4-nitrobenzene at time \((t)\). The apparent rate constant

\[
-k_{app} = -\frac{d[\text{CNB}]}{dt} = k_{app} [\text{CNB}]_0 \quad (2)
\]

on integrating the Eq. 3 yields:

\[
-\ln \left( \frac{[\text{CNB}]}{[\text{CNB}]} \right) = -\ln (1 - X) = k_{app} \cdot t \quad (3)
\]

Using Eq. (4), we can get the \( k_{app} \) value experimentally by plotting \(-\ln (1 - X)\) against time, \((t)\).

**Results and Discussion**

The reaction was conducted on a 250 mL three-necked Pyrex round-bottom flask which permits agitating the solution, inserting the water condenser to recover organic reactant and taking samples and feeding the reactants. This reaction vessel was supported at the centre of the sonicator. A known quantity of chlorobenzene (30 mL, solvent), sodium hydroxide (20 g w/w%), 0.2 g biphenyl IS,(internal standard) were introduced into the reactor. Then, 1.0 g of pyrrole (0.0152 mol) and 2.0 g of 1-chloro-4-nitrophenol (0.0172 mol), 0.3 g of the newly synthesized MPTC (with respect to 1-chloro-4-nitrophenol, limiting reagent) were introduced into the reactor to start the reaction. The reaction mixture was stirred at 300 rpm. The phase separation was almost immediate on ultrasound irradiation (40 kHz, 300 W). Apparent rate constants were evaluated from the plot of \(-\ln (1 - X)\) versus time. As shown in Figure 2, the rate of the reaction increased with increasing in the amount of MPTC along with ultrasound irradiation (40 kHz, 300 W). The \( k_{app} \) values are linearly dependent on the amount of multi-site phase-transfer catalyst. The increasing the \( k_{app} \) value (0 kHz, silent condition: \( k_{app} \approx 7.98 \times 10^{-4}\), min\(^{-1}\)) almost five fold lesser than in the presence of ultrasonication (40 kHz, 300 W: \( k_{app} \approx 27.92 \times 10^{-4}\), min\(^{-1}\)).

**Effect of the amount of newly prepared MPTC**

Experiments were conducted by varying the amount of the newly synthesized MPTC viz., 1,3,5-tribenzy1-1,3,5-triethyl-1,3,5-triazine-1,3,5-triium trichloridebey keeping other experimental parameters are kept constant. The influence of the amount of MPTC on the nitroarylation of pyrrole has been studied by varying amount of MPTC from 0.1 g to 0.5 g with respect to 1-chloro-4-nitrobenzene under ultrasound irradiation (40 kHz, 300 W). Apparent rate constants were evaluated from the plot of \(-\ln (1 - X)\) versus time. As shown in Figure 2, the rate of the reaction increased with increasing in the amount of MPTC along with ultrasound irradiation (40 kHz, 300 W). The \( k_{app} \) values are linearly dependent on the amount of multi-site phase-transfer catalyst. The increasing the \( k_{app} \) value is attributed to the synergetic effect of ultrasound might be enlarged [34,43].

**Effect of the concentration of 1-chloro-4-nitrobenzene**

To investigate the influence of 1-chloro-4-nitrobenzene (CNB) on the kinetics of synthesis of 1-(4-nitrophenyl) pyrrole under ultrasonic irradiation (40 kHz, 300 W) using 1,3,5-tribenzy1-1,3,5-triethyl-1,3,5-triazine-1,3,5-triium trichloridebey keeping other parameters are kept constant. The influence of the concentration of 1-chloro-4-nitrobenzene (CNB) on the speed of agitation was varied in the range of 50-500 rpm along with ultrasound irradiation (40 kHz, 300 W) using 1,3,5-tribenzy1-1,3,5-triethyl-1,3,5-triazine-1,3,5-triium trichloride (MPTC). The results indicate that the rate of the reaction increases linearly as the agitation speed increases from 50 to 300 rpm (Figure 1). However, on further increasing the agitation speed from 300 to 500 rpm, there is no significant improvement in the reaction rate constant. This is because the interfacial area per unit volume of dispersion increased linearly with increasing the stirring speed till 300 rpm is reached, where there is no significant increase in the interfacial area per unit volume of dispersion with the corresponding increase in the speed. Therefore, the agitation speed was set at 500 rpm for studying the reaction phenomena from which the resistance of mass transfer stays at a constant value [34-42]. The \( k_{app} \) values are evaluated from the linear plot of \(-\ln (1 - X)\) versus time. The results indicate that the mechanical effects brought up by the use of low frequency ultrasounds are responsible of the enhancement of the kinetics by harsh mixing, enhancement of mass transfer and so on further, when the same reaction was carried out in the absence of ultrasound, the observed \( k_{app} \) value (0 kHz, silent condition: \( k_{app} \approx 7.98 \times 10^{-4}\), min\(^{-1}\)) almost five fold lesser than in the presence of ultrasonication (40 kHz, 300 W: \( k_{app} \approx 27.92 \times 10^{-4}\), min\(^{-1}\)).

**Figure 1** Effect of stirring speed. Plot of the apparent rate constant versus various stirring speeds: 1 g of pyrrole 20 g of NaOH, 15 mL of H2O, 0.2 g of internal standard (biphenyl), 2.0 g of 1-chloro-4-nitrobenzene, 0.3 g of MPTC, 30 mL of chlorobenzene, 300 rpm, 60°C; ultrasound conditions (40 kHz, 300 W).
irradiation condition (40 kHz, 300 W), the amount of CNB was varied from 1.0 g to 3.0 g. In the presence and absence of ultrasound results are shown in Table 1. The data clearly indicates that the k_app value increases with increasing the amount of CNB. When the 1-chloro-4-nitrobenzene concentration increased, the probability of finding the substrate with active-site of the catalyst and ultrasound enhanced the nitrobenzene concentration increased, the probability of finding the reactants at higher temperature is also increased. Hence, the apparent rate constant is increased at higher temperature. Arrhenius plots were made in Figure 3 of –ln k_app against 1/T to get activation energy of 52.16 kJ.mol⁻¹.

From the literature survey, the dehydrobromination of (2-bromoethyl)benzene catalyzed by tetaoctylammonium bromide (TOAB), an extraction mechanism was proposed [45] due to lower E_a value (<43 kJ.mol⁻¹). In general, higher activation energy (more than 43 kJ.mol⁻¹) suggests an interfacial mechanism [44,46]. The activation energy for the heterogeneous ethylation of phenylactonitrile was reported to be 63.64 kJ.mol⁻¹ and for this an interfacial mechanism was proposed [47]. Further, in the N-alkylation of pyrroleidine-2-one, the Ea (51.35 kJ.mol⁻¹) was reported by Sassoń and Bilman [48], and for this reaction they proposed an interfacial mechanism. They concluded that the deprotonation of the substrate takes place at the interphase and consequently the organic anion is extracted and reacts in the bulk of the organic phase. The rate-determining step in the process is the anion exchange at the interphase. In our study, the observed E_value was 52.36 kJ.mol⁻¹. Hence, we proposed an interfacial mechanism for our present study [49-52].

**Influence of amount of water**

N-Nitroarylation of pyrrole with 1-chloro-4-nitrobenzene (as a limiting agent) under ultrasound condition (40 kHz, 300 W) was examined by varying the amount of water from 5 to 25 mL, under standard reaction conditions. Apparent rate constants were obtained from the plot of –ln(1-X) against time. Generally, the volume of water directly affects both the concentration of sodium hydroxide in the aqueous phase and also generation of anions. Therefore, the conversion (or the reaction rate) will be affected by the volume of water. Figure 4 shows the effect of water on the apparent rate constant. The amount of water was varied from 5 to 30 mL. The data clearly indicates that the k_app value is 52.36 kJ.mol⁻¹. Hence, we proposed an interfacial mechanism for our present study [49-52].
shows the effect of the amount of water on the rate of the reaction. On increasing the volume of water, the concentration of alkali compound in aqueous solution is decreases. This situation would dramatically reveal the hydration effect of the active catalyst \([N\ Q^+]\) (Scheme 3) as the volume of water changed from 30 to 50 mL. From the literature, the kinetic study of the phase-transfer catalyzed etherification of 4,4'-bis(chloromethyl)-1,1'-biphenyl with phenol in an alkaline solution of potassium hydroxide/organic solvent two-phase medium, similar decrease in rate of the reaction on corresponding increase in volume of water was reported [53].

**Effect of ultrasonic power**

Ultrasonic irradiation is defines as acoustic waves with frequencies in the 20 kHz -100 MHz range [24-30]. They create cavities generating locally high temperature and pressures [40-43] or strong electric fields [42-45]. Ultrasound is known to accelerate diverse types of organic reactions and it is established generous reactions, which are otherwise slow due to poor mass transfer are accelerated by sonication due to cavitation [41-45]. It has been reported that a combination of PTC and ultrasound is often better than either of the two techniques alone [43-47]. In such transfer of species across the interface and ultrasound merely facilitates this transfer, possibly by increasing the interfacial area across which this transfer occurs.

To ascertain the influence of various ultrasonic frequencies on the rate of nitroarylation of pyrrole with same output power of 300 W, the ultrasonic frequency was varied in the range of 28 and 40 kHz under otherwise similar conditions using MPTC as the catalyst. Also we followed the reaction under silent condition. The kinetic profile of the reaction is obtained by plotting \(-\ln(1-X)\) against time. In our experimental condition at 30 minutes, without ultrasonic irradiation (silent condition) the \(k_{app}\) values is \(7.98 \times 10^{-3}, \text{min}^{-1}\) but in the presence of ultrasonic condition the \(k_{app}\) values are \(13.46 \times 10^{-3}, \text{min}^{-1}\) and \(27.92 \times 10^{-3}, \text{min}^{-1}\) for 28 kHz (300 W) and 40 kHz.
Effect of organic solvents

In this work, the influence of various organic solvents on the rate of nitroarylation of pyrrole was followed under otherwise standard reaction conditions. Five organic solvents employed in this study are toluene, anisole, cyclohexane, chlorobenzene, and n-hexane. From the plot of $-\ln(1-X)$ against time, the $k_{\text{app}}$ values are shown in the Table 3. From the Table 3, chlorobenzene possesses a higher $k_{\text{app}}$ value among the five organic solvents, due to its higher dielectric constant. In another view the ultrasonic irradiation can enhance the rate in the presence of more polar solvents due to passing higher ultrasonic waves to the reactor and makes fruitful collision between the reactants, and hence we get higher $k_{\text{app}}$ value for chlorobenzene solvent of this system and also this statement is not always true [48,49].
Effect of varying sodium hydroxide concentrations

In the PTC/base catalyzed reactions, the reaction rate is known to be greatly affected by a concentration of the alkaline compound. The rate of nitroarylation of pyrrole strongly depends on the strength of the sodium hydroxide. Kinetic experiments were carried out, by employing 10 to 30 g of NaOH under similar reaction conditions. The Kinetic profile of the reaction is obtained by – ln (1-X) against time. The \( k_{app} \) values tremendously increased with increasing in basicity of OH ion (Table 4). It suggests that the hydroxide ions which are less solvated by water molecules and there by the \( k_{app} \) value increases [49-51].

Mechanism

The experimental result from the present kinetic study indicates that the dependencies of the kinetic data on the entire stirring speed, concentration of the catalyst, aqueous sodium hydroxide and temperature and higher E value are indicative of an interfacial mechanism [49-53]. Initially, the hydroxide anion deprotonates pyrrole at the interface, forming an ion-pair (N\( \text{Na}^- \)). Upon the addition of the catalyst, Q\( + \), ion exchange takes place at the interface (N\( Q^+ \)) and the new formed ion pair N\( Q^+ \) (Scheme 3) which is more organophilicity role of bis-quaternary ammonium salts as phase-transfer catalysts.
