Abstract

We extend chiral perturbation theory to include linear dependence on the lattice spacing $a$ for the Wilson action. The perturbation theory is written as a double expansion in the small quark mass $m_q$ and lattice spacing $a$. We present formulae for the mass and decay constant of a flavor-non-singlet meson in this scheme to order $a$ and $m_q^2$. The extension to the partially quenched theory is also described.

I. INTRODUCTION

Chiral perturbation theory (χPT) is an important tool for extracting quantitative information from lattice simulations of QCD. The reason for this is that it is impractical to have dynamical quarks in simulations that are as light as the up and down quarks, and χPT is needed for a controlled, systematic extrapolation in the quark masses. Since χPT describes continuum QCD at low-energies, its application in numerical simulations is possible only after extrapolating lattice data to the continuum limit where the lattice spacing, a, vanishes.

In this paper, we study the behavior of the Wilson lattice action close to the continuum by incorporating $O(a)$ effects in a reformulation of χPT. A similar approach was first taken in Ref. [1] to investigate the phase diagram for Wilson fermions in two-flavor QCD.

The quark mass matrix (considering only the 2 or 3 lightest quarks) has a special role in QCD — it parameterizes the explicit breaking of the axial symmetries. As a result, the light quark masses appear explicitly in the low-energy effective theory. In this paper, we exploit the fact that for the Wilson lattice action there is another independent symmetry breaking parameter, linear in $a$ [1, 2]. To $O(a)$ this is the only discretization effect, and thus a generalization of the chiral Lagrangian can be written which includes all terms linear in $a$.

II. EFFECTIVE LAGRANGIAN

The Wilson action for fermions is given by

$$S_F^{(W)} = \sum_x \left[ \bar{\psi}(x) \gamma_\mu \Delta_\mu(x) \psi(x) + \bar{\psi}(x)m_q \psi(x) + ar \bar{\psi}(x) \Delta^2 \psi(x) \right],$$

(1)

where

$$\Delta_\mu \psi(x) = \frac{1}{2a} \left[ U_\mu(x) \psi(x + a\hat{\mu}) - U_\mu^\dagger(x - a\hat{\mu}) \psi(x - a\hat{\mu}) \right].$$

(2)

$U_\mu(x)$ is the gauge group valued field defined on the links of the lattice. In typical lattice simulations, $r = 1$ but we will keep it more general for now. Since we are interested in a perturbative study of discretization effects, we follow [3] and consider an effective action in the continuum which describes the same physics as the discrete lattice action (including the gauge action), well below the cutoff $1/a$. The effective action is expanded in powers of $a$:

$$S_{\text{eff}} = S_0 + aS_1 + a^2S_2 + \cdots.$$  

(3)

By construction, $S_0$ is the QCD action. Symmetry considerations restrict the number of mass-dimension 5 operators that appear in $S_1$. The equations of motion can be used to further reduce the list of operators. One then identifies the operators that already appear in $S_0$, which give rise to the renormalization of the quark masses and the coupling constant. Finally, one is left with a single new term at $O(a)$, the Pauli term [2]:

$$aS_1 = ac_{SW} \bar{\psi} \sigma_\mu \psi F_\mu \psi.$$  

(4)

$c_{SW}$ is a constant of $O(1)$ which is a complicated function of the gauge coupling and $r$.

Considering $S_0 + aS_1$ as an underlying theory, it has an $SU(N_f)_L \times SU(N_f)_R$ flavor symmetry which is broken down to the vector part by the mass and Pauli terms with
coefficients $m_q$ and $a_{SW}$ respectively. $\bar{\psi}\psi$ and $\bar{\psi}\sigma_{\mu\nu}F^{\mu\nu}\psi$ break the axial symmetry in the same way and therefore, from a spurion analysis point of view, $m_q$ and $a_{SW}$ are on equal footing, as noted in Ref. [1]. In particular, $a_{SW}$ is treated as a non-trivial matrix in flavor space, just like $m_q$. It is possible to give $a_{SW}$ a flavor structure in simulations by promoting the constant $r$ to a matrix. This can supply extra “knobs” which can aid the continuum extrapolations. The squares of the Goldstone boson (GB) masses are linear in the symmetry breaking matrices of parameters $[1]$, conveniently written as:

$$\chi \equiv 2B_0m_q \ , \quad \rho \equiv 2W_0a_{SW} .$$

$B_0$ and $W_0$ are unknown dimensionful parameters that appear in the effective Lagrangian at leading order (LO) which is defined below.

$\chi$PT for the Wilson action (which will be denoted by $W_{\chi}$PT) is an expansion in the squares of the small momenta $p$ and the small pseudo Goldstone boson masses. We formally consider the expansion to be in two independent small parameters:

$$\epsilon \sim \frac{p^2}{\Lambda^2} \sim \frac{\chi}{\Lambda^2} \quad \text{and} \quad \delta \sim \frac{\rho}{\Lambda^2} .$$

$\Lambda_{\chi}$ is the scale where new high-energy physics enters and the effective field theory (EFT) no longer describes the correct physics. This happens around the mass of the rho meson, or roughly $\Lambda_{\chi} \sim 1\text{GeV}$. From dimensional analysis, and the fact that $B_0$ and $W_0$ depend only on the high-energy details, one can check that the expansion is in fact in $m_q/\Lambda_{\chi}$ and in $a\Lambda_{\chi}$.

Since Eq. (3) is truncated at $O(a)$ it makes no sense to go beyond $O(\delta)$ in $W_{\chi}$PT (we remark on $O(a^2)$ corrections in the next section). For convenience, we choose to collect terms in the LO and next-to-leading order (NLO) Lagrangians as follows:

$$\begin{align*}
\text{LO} : \quad & L_2 \sim O(\epsilon, \delta) , \\
\text{NLO} : \quad & L_4 \sim O(\epsilon^2, \epsilon \delta) .
\end{align*}$$

The underlying hierarchy consistent with this choice is $\{\epsilon, \delta\} \gg \{\epsilon^2, \epsilon \delta\} \gg \delta^2$, and the last inequality also implies $\epsilon \gg \delta$. In practice, the perturbative expansion should be organized according to the actual sizes of the expansion parameters, which are determined by the quark masses in the simulation and the size of the lattice spacing. For example, if the simulations are done so close to the continuum that $\delta$ is very small, it might make more sense to have the LO Lagrangian be $O(\epsilon)$, and at NLO $O(\epsilon^2, \epsilon \delta)$. With our convention,

$$L_2 = \frac{f^2}{4} \text{tr}(\partial \Sigma \partial \Sigma^\dagger) - \frac{f^2}{4} \text{tr}((\chi + \rho)\Sigma^\dagger + \Sigma(\chi^\dagger + \rho^\dagger)) ,$$

is the LO Lagrangian, where $\Sigma = \exp(2i\Pi/f)$ contains the matrix of meson fields, $\Pi$. It is useful to note that Eq. (4) can be “produced” from the LO Lagrangian of ordinary $\chi$PT by the substitution $\chi \to \chi + \rho$.

The NLO Lagrangian is:

$$L_4 = L_1 \langle \partial \Sigma \partial \Sigma^\dagger \rangle^2 + L_2 \langle \partial_{\mu} \Sigma \partial_{\nu} \Sigma^\dagger \rangle \langle \partial_{\mu} \Sigma \partial_{\nu} \Sigma^\dagger \rangle + L_3 \langle (\partial \Sigma \partial \Sigma^\dagger)^2 \rangle + L_4 \langle \partial \Sigma \partial \Sigma^\dagger \rangle \langle \chi^\dagger \Sigma + \Sigma^\dagger \chi \rangle + L_5 \langle \partial \Sigma \partial \Sigma^\dagger \rangle \langle \rho^\dagger \Sigma + \Sigma^\dagger \rho \rangle + L_6 \langle \partial \Sigma \partial \Sigma^\dagger \rangle \langle \chi^\dagger \Sigma + \Sigma^\dagger \chi \rangle + L_7 \langle \partial \Sigma \partial \Sigma^\dagger \rangle \langle \rho^\dagger \Sigma + \Sigma^\dagger \rho \rangle + L_8 \langle \chi^\dagger \Sigma + \Sigma^\dagger \chi \rangle^2 + W_6 \langle \chi^\dagger \Sigma + \Sigma^\dagger \chi \rangle \langle \rho^\dagger \Sigma + \Sigma^\dagger \rho \rangle + L_9 \langle \chi^\dagger \Sigma - \Sigma^\dagger \chi \rangle^2 + W_7 \langle \chi^\dagger \Sigma - \Sigma^\dagger \chi \rangle \langle \rho^\dagger \Sigma - \Sigma^\dagger \rho \rangle + L_{10} \langle \chi^\dagger \Sigma + \Sigma^\dagger \chi \rangle \langle \rho^\dagger \Sigma + \Sigma^\dagger \rho \rangle .$$
The angled brackets stand for traces over the flavor indices. In the limit \( a \to 0 \), the \( L_i \)'s above are the usual Gasser-Leutwyler (GL) coefficients of \( \chiPT \).

A word about certain \( \log(a\Lambda) \) corrections is appropriate here. In the EFT formulation, the Lagrangian is written in terms of the most general set of operators constructed out of the relevant degrees of freedom that respect the symmetries of the theory. The high-energy physics that was integrated out enters through the unknown couplings that multiply these operators. Thus the low-energy constants or couplings are entirely determined by the high-energy scales. In \( \chiPT \), the operators contain only the light meson and photon fields, and the low-energy constants \( B_0, f, L_i \), etc., are functions of the QCD scale \( \Lambda_{QCD} \). In particular, the \( L_i \)'s are independent of the pion masses \( m_\pi \sim \sqrt{m_q} \) which are associated with the long-distance physics. All the \( m_q \) dependence of \( \chiPT \) is explicitly written in the operators. This still holds for the \( m_q \) dependence of the \( W_\chiPT \) Lagrangian written above, but the same cannot be said about the lattice spacing \( a \). It is true that an \( \mathcal{O}(a) \) term breaks the chiral symmetry in the same way as \( m_q \), and \( a\Lambda^2 \) is a soft scale associated with the pseudo GB mass, but \( 1/a \) is not a soft scale — it acts as the ultra-violet cutoff for the discrete lattice. Thus, while the low-energy constants of \( W_\chiPT \) are expected to be independent of \( m_q \) and \( ac_{SW} \), they could in principal have a complicated dependence on the gauge coupling \( g \) (in \( S_0 \)), which itself depends on \( a \). However, the running of the coupling constant is determined in simulations by requiring that as one approaches the continuum, some chosen physical quantity remains fixed. Effectively, this means that the coupling \( g \) and the cutoff \( 1/a \) combine to give the only real scale in the theory \( -\Lambda_{QCD} \) — and the continuum limit is approached smoothly. We therefore expect the \( L_i \)'s and \( W_i \)'s to depend on \( \Lambda_{QCD} \), and only weakly on \( a \), the latter dependence coming from higher orders in perturbation theory, or involving higher powers of \( a \) which can always be expanded. \(^1\)

The parameter \( c_{SW} \) in the action \( S_1 \) will still depend on \( \log(a\Lambda_{QCD}) \), and it might be possible to calculate these dependences explicitly in perturbation close to the continuum \(^4\) \[\bar{m}_q = m_q - m_q^c(a), \tag{11}\]

and it is \( \bar{m}_q \) that should be used in Eqs. (9), (10). \( \bar{m}_q \) compensates for the large \( \mathcal{O}(1/a) \) shift in the quark masses, but it also contains positive powers of \( a \). This is not a problem — redefinitions of the mass parameter of this sort only lead to changes in the \( W_i \)'s. The GL coefficients are not affected because the operators with which they are associated do not contain \( a \). The re-shuffling of the \( W_i \)'s does mean, however, that their actual numerical values depend on the prescription that is used to determine \( m_q^c(a) \) and to define \( \bar{m}_q \).

Note that the chiral limit cannot be taken by simply setting \( \bar{m}_q \to 0 \). While \( m_q^c \) satisfies \( M^2_\pi(m_q^c(a), a) = 0 \), there is no reason that other quantities will attain their chiral limit for this value of \( m_q \). This is a reflection of the fact that there really are 2 different operators that break the symmetry.

\(^1\) We thank Paulo Bedaque and Andrew Cohen for helping us understand this issue.
III. APPLICATIONS

In the following two subsections we calculate the expressions for the mass and decay constant of a flavor-charged meson with the flavor indices $AB$ ($A \neq B$) having the same quantum numbers as $\bar{\psi}_B \gamma_5 \psi_A$. In the calculations that follow we take $\chi$ to be a diagonal matrix with entries $(\chi)_{ii} = \chi_i$, and use the notation $\chi_{AB} = (\chi_A + \chi_B)/2$. Note that this notation coincides with the standard way of denoting matrix elements only for the diagonal entries. The same convention is used for $\rho$. It is convenient to define another matrix, $\mu = \chi + \rho$, which is the combination that appears in $L_2$. The subscript notation for $\mu$ follows that of $\chi$ and $\rho$, except for the quantities $\mu_\pi$ and $\mu_\eta$ which are defined below.

A. Masses

The mass of a flavor-charged meson in $W_\chi$PT with three quark flavors is given through NLO by

$$M_{AB}^2 = (M_{AB}^2)_{LO} + (M_{AB}^2)_{NLO,\,\text{loop}} + (M_{AB}^2)_{NLO,\,\text{tree}}, \tag{12}$$

with

$$(M_{AB}^2)_{LO} = \mu_{AB}, \tag{13}$$

$$(M_{AB}^2)_{NLO,\,\text{loop}} = \frac{1}{48 f^2 \pi^2} \mu_{AB} \sum_{x=\pi,\eta} R_{x}^{AB} \mu_x \log \mu_x, \tag{14}$$

$$(M_{AB}^2)_{NLO,\,\text{tree}} = -\frac{24}{f^2} L_4 (\chi_{AB} + \rho_{AB}) \bar{\chi} - \frac{24}{f^2} W_4 \chi_{AB} \bar{\rho} - \frac{8}{f^2} L_5 (\chi_{AB} + \rho_{AB}) \chi_{AB} - \frac{8}{f^2} W_5 \chi_{AB} \rho_{AB} + \frac{24}{f^2} 2 L_6 \chi_{AB} \bar{\chi} + \frac{24}{f^2} W_6 (\chi_{AB} \bar{\rho} + \rho_{AB} \bar{\chi}) + \frac{24}{f^2} 2 L_8 \chi_{AB}^2 + \frac{8}{f^2} 2 W_8 \chi_{AB} \rho_{AB}, \tag{15}$$

where $\mu_\pi$ and $\mu_\eta$ are the squares of the LO masses of the two light flavor-neutral mesons, given implicitly by

$$\mu_\pi + \mu_\eta = 2 \bar{\mu}, \tag{16}$$

$$\mu_\pi \mu_\eta = \mu_1 \mu_2 + \mu_1 \mu_3 + \mu_2 \mu_3. \tag{17}$$

Here $\bar{\chi} = tr(\chi)/3$ and similarly for $\rho$ and $\mu$. Also, if we denote by $C$ the flavor that is different from both $A$ and $B$, we have

$$R_{\pi}^{AB} = \frac{\mu_C - \mu_\pi}{\mu_\eta - \mu_\pi}, \quad R_{\eta}^{AB} = \frac{\mu_C - \mu_\eta}{\mu_\pi - \mu_\eta}. \tag{18}$$

In deriving the expressions for the mass in $W_\chi$PT one could use a very convenient “trick” relating these expressions to the corresponding expressions in ordinary $\chi$PT. As mentioned earlier, the LO Wilson chiral Lagrangian $L_2$, Eq. [3], can be obtained from $\chi$PT LO Lagrangian by the simple substitution $\chi \to \chi + \rho$ (or $\chi \to \mu$). Thus any quantity $h(\chi)$ in $\chi$PT that depends only on the LO Lagrangian can be trivially reproduced in $W_\chi$PT according to $h(\chi) \to h(\chi + \rho)$. This is true for the LO and NLO loop diagrams that contribute to the mass. Similar results also hold for the decay constant. We provide the expressions for the mass in ordinary $\chi$PT in Appendix [4] for comparison.
B. Decay constants

The decay constant is given through NLO by:

\[ f_{AB} = (f_{AB})_{\text{LO}} + (f_{AB})_{\text{NLO, loop}} + (f_{AB})_{\text{NLO, tree}}, \]

with

\[ (f_{AB})_{\text{LO}} = f, \]

\[ (f_{AB})_{\text{NLO, loop}} = -\frac{1}{64\pi^2 f} \sum_{i=1,2,3} \mu_{ij} \log \mu_{ij} + \frac{1}{192\pi^2 f} (\mu_A - \mu_B) \left\{ \log \left( \frac{\mu_A}{\mu_B} \right) + \right. \]

\[ \left. + \sum_{x=\pi,\eta} R^{AB}_x \mu_x \left[ \log \left( \frac{\mu_A/\mu_x}{\mu_A - \mu_x} \right) - \log \left( \frac{\mu_B/\mu_x}{\mu_B - \mu_x} \right) \right] \right\}, \]

\[ (f_{AB})_{\text{NLO, tree}} = \frac{12}{f} (L_4 \bar{\chi} + W_4 \bar{\rho}) + \frac{4}{f} (L_5 \chi_{AB} + W_5 \rho_{AB}). \]

C. W\chi PT, O(a^2), and improvement

In the simplest sense, the expressions for the mass and decay constant in W\chi PT can be used to aid in taking the continuum limit. These forms provide all the linear \( a \) dependence, as well as non-trivial logarithms that involve \( a \) and \( m_q \). A test of these formulae would be to check whether they describe the \( a \) dependence better than naive extrapolations. Perhaps a more useful way to think about it is that with these expressions one can determine the GL coefficients directly from lattice data at finite \( a \).

What about higher orders in \( a \)? At order \( a^2 \) the picture changes qualitatively. There are operators in \( S_2 \), such as \( \bar{\psi}D\mu D\mu \psi \), that do not break the chiral symmetry. This means that \( a \) can no longer be associated only with symmetry breaking effects, and spurion analysis cannot be used to constrain the \( a^2 \) operators. Nevertheless, we might still expand in \( \epsilon \) and \( \delta \) simultaneously. The LO, \( O(\epsilon, \delta) \) Lagrangian, and consequently the LO mass and decay constant are unchanged. At NLO, \( O(\epsilon^2, \epsilon\delta, \delta^2) \), there are several \( O(a^2) \) operators that are added to the Lagrangian, but they are all independent of the quark masses and do not contain derivatives. Consequently, the only correction to the meson masses at this order is an additional term of the form \( \omega a^2 \), where \( \omega \) is an unknown constant of mass-dimension 4. The expression for the decay constant does not receive any corrections at this order. This is because tree level contributions to the decay constant can only come from operators that contain derivatives.

Improvement schemes (first suggested by Symanzik in Ref. [3]) — using an improved action and improved operators — are another important tool for studying and reducing discretization effects. Using improved action involves adding a discretized version of the Pauli term in Eq. (4) to the Wilson action in Eq. (1) which exactly cancels the \( S_1 \) term in the continuum action, Eq. (3). This means that up to \( O(a^2) \) the lattice theory is just QCD, and at low-energies we expect \( \chi PT \) to be a good description. From the perspective of W\chi PT this is equivalent to saying that using an improved action sets all \( W_i = 0 \). This is of course not surprising; the use of improved action is meant to eliminate all \( O(a) \) dependence from observables, and the \( W_i \) coefficients parameterize exactly this dependence. One should
not conclude from this that improving the action is enough for complete $\mathcal{O}(a)$ improvement. As mentioned above, some dimension-5 operators that are allowed by the symmetries, and can therefore appear in $S_1$, are implicitly absorbed in $S_0$ by replacing the bare parameters of $S_0$ with renormalized ones. This is a necessary step, and it is compatible with the fact that in improvement schemes, in addition to using an improved action, one must use improved operators.

IV. PARTIALLY QUENCHED THEORIES

$W\chi PT$ is appropriate for the type of lattice simulations which are called “unquenched”. These are simulations in which there are 2 or 3 dynamical fermions (also called “sea quarks”), and expectation values are calculated of operators which are constructed from a different type of fermions (“valence quarks”) which have the same masses as the sea quarks. In most lattice simulations, however, the masses of the valence quarks are not taken to be the same as those of the sea quarks. Simulations that are done this way are called partially quenched (PQ). Theoretically this can be described by a QCD-like construction which includes ghosts [6, 7]. The low-energy behavior of these theories is described by PQ $\chi PT$ [7], which has the same unknown low-energy constants as $\chi PT$ for ordinary QCD [8]. Thus, PQ simulations provide additional mass parameters that can be used to probe the theory in a larger parameter space, and gain better statistics in determining the GL coefficients [9, 10]. It is of clear practical value to consider the generalization of $W\chi PT$ to the PQ case.

PQ QCD contains three different types of spin-half particles — valence quarks, sea quarks, and ghosts which obey Bose-Einstein statistics. There is a single ghost flavor for every valence quark, and they both have the same mass. The quark mass matrix for a theory with 2 valence quarks, 3 sea quarks, and 2 ghosts is

$$m_q = \text{diag}(m_A, m_B, m_1, m_2, m_3; m_A, m_B).$$

(23)

$\chi PT$ for PQ QCD is constructed in terms of this matrix, or in terms of $\chi$ which is still defined through Eq. (1), and the result is a Lagrangian identical to the one for ordinary $\chi PT$, but with an extended flavor structure and with super-traces replacing the traces. Because of the great formal similarity between QCD and PQ QCD, the extension of PQ $\chi PT$ to PQ $W\chi PT$ is a simple generalization of the discussion in the previous section. In particular, the LO and NLO Lagrangians for PQ $W\chi PT$ have forms just like in Eqs. (9), (10), with traces replaced by super-traces. Further, as in the continuum PQ $\chi PT$, the low-energy constants $L_i$’s and $W_i$’s are exactly the same in the unquenched and PQ $W\chi PT$. It follows that one can use the Wilson chiral expressions for PQ theories to extract the GL coefficients.

For completeness, we provide the expressions for the mass and decay constant for PQ $W\chi PT$ in Appendix B. Again, as in unquenched theories, the LO and NLO loop results in PQ $W\chi PT$ are trivially related to the corresponding results in PQ $\chi PT$ which have been calculated in [8].

V. SUMMARY

We constructed a low-energy EFT, $W\chi PT$, of the Wilson lattice action close to the continuum. The theory extends $\chi PT$, and the perturbative framework is described in terms of
two small parameters — the quark mass $m_q$ and the lattice spacing $a$. The Gasser-Leutwyler chiral Lagrangian (through $\mathcal{O}(p^4)$ in $\chi$PT) was modified to incorporate all linear dependence on $a$. We applied this theory to calculate light meson masses and decay constants. The resulting expressions capture all the linear dependence on $a$ as well as non-trivial logarithms that entangle $a$ and $m_q$. A useful application of this theory is the determination of the Gasser-Leutwyler coefficients of ordinary $\chi$PT from lattice simulations at small but finite $a$.

APPENDIX A: $\chi$PT RESULTS

We present the expressions for the mass of a flavor-charged light meson in $\chi$PT for comparison with $W_{\chi}$PT results. As explained in the text, one can see that the LO and NLO loop expressions in $W_{\chi}$PT can be obtained from the corresponding $\chi$PT results with the substitution $\chi \rightarrow \chi + \rho$ ($\chi \rightarrow \mu$). Using the same notation as in Eqs. (13)-(18), the masses through NLO with three quark flavors are [9]:

$$M_{AB}^2 = (M_{AB}^2)_{\text{LO}} + (M_{AB}^2)_{\text{NLO, loop}} + (M_{AB}^2)_{\text{NLO, tree}},$$ (A1)

with

$$(M_{AB}^2)_{\text{LO}} = \chi_{AB},$$ (A2)

$$(M_{AB}^2)_{\text{NLO, loop}} = \frac{1}{48f^2 \pi^2} \chi_{AB} \sum_{x=\pi,\eta} R_{x}^{AB} \chi_x \log \chi_x, $$ (A3)

$$(M_{AB}^2)_{\text{NLO, tree}} = \frac{24}{f^2} (2L_6 - L_4) \chi_{AB} \bar{\chi} + \frac{8}{f^2} (2L_8 - L_5) \chi_{AB}^2,$$ (A4)

where

$$\chi_{\pi} + \chi_{\eta} = 2 \bar{\chi},$$ (A5)

$$\chi_{\pi} \chi_{\eta} = \chi_1 \chi_2 + \chi_1 \chi_3 + \chi_2 \chi_3,$$ (A6)

$$R_{x}^{AB} = \frac{\chi_C - \chi_{x}}{\chi_{x} - \chi_{\pi}}, \quad R_{\eta}^{AB} = \frac{\chi_C - \chi_{\eta}}{\chi_{\pi} - \chi_{\eta}}.$$ (A7)

(Here, again, $C$ is the flavor that is different from both $A$ and $B$.)

APPENDIX B: PQ $W_{\chi}$PT RESULTS

The forms of the Lagrangians in unquenched and PQ theory are the same, with an implicit difference in the structure of the matrices in flavor space and the replacement of traces with super-traces. Thus all tree contributions in both theories have the same dependence on $\chi$.
and $\rho$. In particular, the LO and NLO tree results are still given by Eqs. (13), (15) and Eqs. (20), (22) for the mass and the decay constant respectively, with appropriate $\chi$ and $\rho$ matrices for PQ simulations (the structure of $\rho$ in PQ $\chi$PT is determined by $r$ in the PQ version of the Wilson action. The latter must have a structure similar to $m_q$, eq. (23), that is needed to guarantee the exact cancellation between valence and ghost loops.). We give here only the NLO loop results, which are different from the unquenched expressions.

\[
(M_{AB}^2)_{\text{NLO, loop}} = \frac{1}{16 f^2 \pi^2 N} \mu_{AB} \sum_{x=A,B,\pi,\eta} R_x \mu_x \log(\mu_x), \tag{B1}
\]

\[
(f_{AB})_{\text{NLO, loop}} = -\frac{1}{64 \pi^2 f} \sum_{i=1,2,3} \mu_{ij} \log(\mu_{ij}) + \frac{1}{192 \pi^2 f} \left\{-D_A - D_B \right.
\]
\[+ \frac{\log(\mu_A/\mu_B)}{\mu_A - \mu_B} \left[ \mu_A D_A + \mu_B D_B + (\mu_A - \mu_B)^2 \right]
\]
\[+ \sum_{x=\pi, \eta} R_x \mu_x (\mu_A - \mu_B) \left[ \frac{\log(\mu_A/\mu_x)}{\mu_A - \mu_x} - \frac{\log(\mu_B/\mu_x)}{\mu_B - \mu_x} \right] \} , \tag{B2}
\]

where

\[
R_x = \frac{\prod_{i=1,2,3} (\mu_i - \mu_x)}{\prod_{y=A,B,\pi,\eta} y \neq x (\mu_y - \mu_x)}, \quad D_x = \frac{\prod_{i=1,2,3} (\mu_i - \mu_x)}{(\mu_\pi - \mu_x)(\mu_\eta - \mu_x)}. \tag{B3}
