Covariant Constitutive Relations and Relativistic Inhomogeneous Plasmas

J Gratus\textsuperscript{1} and R W Tucker\textsuperscript{1}

\textit{Physics Department Lancaster University and the Cockcroft Institute}

The notion of a two-point susceptibility kernel used to describe linear electromagnetic responses of dispersive continuous media in non-relativistic phenomena is generalized to accommodate the constraints required of a causal formulation in spacetimes with background gravitational fields. In particular the concepts of spatial material inhomogeneity and temporal non-stationarity are formulated within a fully covariant spacetime framework. This framework is illustrated by re-casting the Maxwell-Vlasov equations for a collisionless plasma in a form that exposes a 2-point electromagnetic susceptibility kernel in spacetime. This permits the establishment of a perturbative scheme for non-stationary inhomogeneous plasma configurations. Explicit formulae for the perturbed kernel are derived in both the presence and absence of gravitation using the general solution to the relativistic equations of motion of the plasma constituents. In the absence of gravitation this permits an analysis of collisionless damping in terms of a system of integral equations that reduce to standard Landau damping of Langmuir modes when the perturbation refers to a homogeneous stationary plasma configuration. It is concluded that constitutive modelling in terms of a 2-point susceptibility kernel in a covariant spacetime framework offers a natural extension of standard non-relativistic descriptions of simple media and that its use for describing linear responses of more general dispersive media has wide applicability in relativistic plasma modelling.

I. INTRODUCTION

The behaviour of a material medium in response to electromagnetic and gravitational fields encompasses a vast range of classical and quantum physics. For media composed of a large collection of molecular or ionized structures recourse to a statistical description is required and this often leads to a coarser description in terms of a few thermodynamic variables and their correlations. Such a description relies on the efficacy of particular constitutive models or phenomenological constitutive data that serve to circumscribe its domain of applicability.

For phenomena where the relative motions of the constituents approach the speed of light in vacuo or the material experiences bulk accelerations or gravitational interactions such constitutive descriptions must be formulated within a relativistic framework. However even within a spacetime covariant formulation there remains great freedom in how to accommodate electromagnetic responses that depend on material dispersion induced by spatial correlations or temporal delays of electromagnetic interactions. The incorporation of such effects in a theoretical description often relies on a detailed structural model of the medium particularly if it is inhomogeneous or external gravitational gradients are relevant. Notwithstanding these complexities simple constitutive models have proved of considerable value for homogeneous polarizable media that exhibit temporal dispersion in a laboratory frame where gravity plays no essential role. Indeed the notion of permittivity and permeability tensors is often adequate to parametrize a large range of experimental linear responses of simple polarizable media to external static and dynamic electromagnetic fields. More generally, for non-dispersive media these tensors can be subsumed into a susceptibility kernel that readily accommodates special relativistic effects on the bulk motion of media.

In this article the degree to which the notion of a susceptibility kernel can be generalized to describe linear electromagnetic responses of dispersive continuous media is explored. In particular the effects of spatial material inhomogeneity and non-stationarity will be formulated within a fully covariant spacetime framework. In this manner the formulation can accommodate arbitrary gravitational and electromagnetic interactions. The framework will be illustrated by re-casting the Maxwell-Vlasov equations for a collisionless plasma in a form that exposes a 2-point electromagnetic susceptibility kernel in an arbitrary external gravitational field. This permits the establishment of a perturbative scheme for non-stationary
inhomogeneous plasma configurations in terms of such a kernel. Explicit formulae for the perturbed kernel are derived in both the presence and absence of gravitation in terms of the general solution to the equations of motion of the plasma constituents. In the absence of gravitation this permits an analysis of collisionless damping in terms of a system of integral equations that reduce to standard Landau damping of Langmuir modes when the perturbation refers to a homogeneous stationary plasma configuration.

It is concluded that constitutive modelling in terms of a 2-point susceptibility kernel in a covariant spacetime framework offers a natural extension of standard non-relativistic descriptions of simple media and that its use for describing linear responses of more general dispersive media has wide applicability in relativistic plasma modelling.

II. CONSTITUTIVE RELATIONS

In the following spacetime $M$ is considered a globally hyperbolic, topologically trivial four dimensional manifold endowed with a metric tensor $g$ with signature $(-1, +1, +1, +1)$ describing gravitation. A closed 2-form $F$ describes the electromagnetic field. The bundle of exterior $p-$forms over $M$ is denoted $\Lambda^p M$ and its sections $\Gamma \Lambda^p M$ are $p-$forms on $M$. The bundle of all forms is $\Lambda M = \bigcup_{p=0}^{4} \Lambda^p M$. Associated with $g$ is the Hodge map $\ast$. Thus for $\alpha \in \Gamma \Lambda^p M$ its corresponding Hodge dual is denoted $\ast \alpha \in \Gamma ^{4-p} \Lambda M$. The tangent bundle over $M$ is denoted $TM$ and its sections $\Gamma TM$ are vector fields on $M$. We call the 1-form $\tilde{J} = g(J, -) \in \Gamma \Lambda^1 M$ the metric dual of the vector field $J \in \Gamma TM$. Maxwell’s equations for the electromagnetic field $F \in \Gamma \Lambda^2 M$ in a polarizable medium containing an electric current $J \in \Gamma TM$, satisfying the continuity (or current conservation) equation $d \ast \tilde{J} = 0$, are written

$$dF = 0 \quad \text{and} \quad d \ast G = - \ast \tilde{J}$$

(1)

The excitation 2-form $G \in \Gamma \Lambda^2 M$ can always be expressed

$$G = \epsilon_0 F + \Pi$$

(2)

in terms of the permittivity $\epsilon_0$ of free space. The polarization 2-form $\Pi \in \Gamma \Lambda^2 M$ results from all electromagnetic field sources not made explicit in $J$.

In general $\Pi$ and $J$ are non-linear functionals of $F$ and other fields such as matter and initial data on any initial spacelike hypersurface $\Sigma_M \subset M$. Such functionals are the constitutive relations describing $G$ and $J$ in terms of $F$ and these other fields.
It is convenient to introduce integration on a fibred manifold \( \mathcal{N} \) of dimension \( n + r \) with projection \( \pi_{\mathcal{N}} : \mathcal{N} \to N \) over a manifold \( N \) of dimension \( n \). Thus at each point \( \sigma \in N \) one has the fibre \( \mathcal{N}_\sigma = \pi_{\mathcal{N}}^{-1}\{\sigma\} = \{ (\sigma', \varsigma) \in \mathcal{N} \mid \pi_{\mathcal{N}}(\sigma', \varsigma) = \sigma \} \) so \( \text{dim}(\mathcal{N}_\sigma) = r \) is the fibre dimension. For \( \alpha \in \Gamma_{\Lambda^{p+r}}\mathcal{N} \) we define the form \( \triangle \int_{\pi_{\mathcal{N}}} \alpha \in \Gamma_{\Lambda^p}N \) by

\[
\int_{\mathcal{N}} \beta \wedge \triangle \int_{\pi_{\mathcal{N}}} \alpha = \int_{\mathcal{N}} \pi_{\mathcal{N}}^* (\beta) \wedge \alpha
\]

for all \( \beta \in \Gamma_{\Lambda^{n-p}}N \).

In terms of local coordinates \((\sigma^1, \ldots, \sigma^n)\) and \((\sigma^1, \ldots, \sigma^n, \varsigma^1 \ldots \varsigma^r)\) for patches on \( N \) and \( \mathcal{N} \) respectively, one may write the fibre integral

\[
\left( \frac{\int_{\pi_{\mathcal{N}}} \alpha}{|\sigma|} \right) = \sum_{1 \leq I_1 < \ldots < I_p \leq n} d\sigma^i_1 \wedge \ldots \wedge d\sigma^i_p \int_{\mathcal{N}_\sigma} i_{\partial/\partial \sigma^{I_1}} \ldots i_{\partial/\partial \sigma^{I_p}} \alpha|_{(\sigma, \varsigma)}
\]

(4)

where \( \mathcal{N}_\sigma = \pi_{\mathcal{N}}^{-1}\{\sigma\} \) is the fibre over the point \( \sigma \in N \) and \( i_{\partial/\partial \sigma^{I_1}} \) is the contraction on forms. Observe that if \( \alpha \) does not contain the factor \( d\varsigma^1 \wedge \ldots \wedge d\varsigma^r \) then \( \int_{\pi_{\mathcal{N}}} \alpha = 0 \). The proof of this is given in appendix lemma 2.

A key result of fibre integration, used to establish the current continuity equation, is that it commutes with the exterior derivative:

\[
\left( d \int_{\pi_{\mathcal{N}}} \alpha \right)_{|\sigma} = \left( \int_{\pi_{\mathcal{N}}} d\alpha \right)_{|\sigma}
\]

(5)

for \( \sigma \) not on the boundary of \( N \) provided the support of \( \alpha \) does not intersect the boundary of \( \mathcal{N} \). The proof is given in appendix lemma 3.

In general models for \( \Pi \) demand a knowledge of the dynamics of sources responsible for polarization as well as any permanent polarization that may exist in the medium. A full dynamical description depends on a specification of appropriate initial value data \( \zeta \) on \( \Sigma_M \).

The exact structure of \( \zeta \) depends on the sources of the polarization. For the plasma model described in section II the initial data corresponds to the velocity profile for each particle species at each point on \( \Sigma_M \) in the plasma.

In this article \( \Pi \) is considered to be an affine functional of \( F \) of the form

\[
\Pi[F, \zeta] = \int_{p_x} \chi \wedge p_x^*(F) + Z[\zeta]
\]

(6)

for some functional \( Z \) of \( \zeta \). The first term on the right is expressed in terms of the fibre integral of a two-point susceptibility kernel \( \chi \in \Gamma_{\Lambda^4}(M_X \times M_Y) \) expressible locally as

\[
\chi = \frac{1}{4} \chi_{abcd}(x, y) dx^a \wedge dx^b \wedge dy^c \wedge dy^d
\]

(7)
Here $M_X$ and $M_Y$ are two copies of $M$, locally coordinated by $(x^0, \ldots, x^3)$ and $(y^0, \ldots, y^3)$ respectively, with projections $p_X : M_X \times M_Y \to M_X$, $p_Y : M_X \times M_Y \to M_Y$, $p_X(x, y) = x$, $p_Y(x, y) = y$ and initial hypersurfaces $\Sigma_{M_X} \subset M_X$ and $\Sigma_{M_Y} \subset M_Y$. Throughout, summation is over Roman indices $a, b, c = 0, 1, 2, 3$ and Greek indices $\mu, \nu, \sigma = 1, 2, 3$.

To consistently remove any reference to $M$ (without a subscript) let $F \in \Gamma^{\Lambda^2 M_Y}$, $\epsilon_0 F \in \Gamma^{\Lambda^2 M_X}$, $G \in \Gamma^T M_X$ and $\Pi[F, \zeta] \in \Gamma^{\Lambda^2 M_X}$. Thus $\epsilon_0$ can be regarded as a map $\epsilon_0 : \Gamma^{\Lambda^2 M_Y} \to \Gamma^{\Lambda^2 M_X}$ which is the pullback of the natural isomorphism $M_X \to M_Y$, together with a scaling to accommodate the choice of electromagnetic units.

In terms of local coordinate bases on $M_X$ and $M_Y$ the components of (6) are

$$\Pi[F, \zeta]_{ab}(x) = \int_{y \in M} \frac{1}{4} \chi_{abcd}(x, y) F_{ef}(y) dy^{cdef} + Z[\zeta]_{ab} \tag{8}$$

in a multi-index notation with

$$dx^{a_1 \cdots a_p} \equiv dx^{a_1} \wedge \cdots \wedge dx^{a_p}$$

and

$$i_{(x)}^{(a_1 \cdots a_p)} \equiv i \frac{\partial}{\partial x^{a_p}} \cdots i \frac{\partial}{\partial x^{a_1}}$$

(Note the reverse order for internal contraction.) Summations over multi-indices $I \subset \{1, \ldots, n\}$ considered as an ordered $p$-list $I_1 < I_2 < \ldots < I_p$ of length $|I| = p$ will also be employed. Thus

$$dx^I \equiv dx^{I_1 \cdots I_p} = dx^{I_1} \wedge \cdots \wedge dx^{I_p}$$

and

$$i_I^{(x)} \equiv i_{I_1}^{(x)} \cdots i_{I_p}^{(x)} = i \frac{\partial}{\partial x^{I_p}} \cdots i \frac{\partial}{\partial x^{I_1}}$$

so that, via summation, if $\alpha \in \Gamma^{\Lambda^p M}$ then $dx^I \wedge i_I^{(x)} \alpha = \alpha$ where $|I| = p$.

In this notation the product manifold $M_X \times M_Y$ inherits the following maps that will be
employed below:

\begin{align*}
  d_X : \Lambda^p(M_X \times M_Y) &\rightarrow \Lambda^{p+1}(M_X \times M_Y), \\
  d_X(\alpha) &= \frac{\partial \alpha_{IJ}}{\partial x^a} dx^a \wedge dx^I \wedge dy^J \\
  d_Y : \Lambda^p(M_X \times M_Y) &\rightarrow \Lambda^{p+1}(M_X \times M_Y), \\
  d_Y(\alpha) &= \frac{\partial \alpha_{IJ}}{\partial y^a} dy^a \wedge dx^I \wedge dy^J \\
  \star_X : \Lambda(M_X \times M_Y) &\rightarrow \Lambda(M_X \times M_Y), \\
  \star_X(\alpha) &= \alpha_{IJ} \star dx^I \wedge dy^J
\end{align*}

where \( \alpha = \alpha_{IJ} dx^I \wedge dy^J \).

Since \( F = dA \) and for \( A \) with compact support away from any boundary of \( M_Y \) it follows from (6) that

\[
\Pi[F, \zeta] = -\int_{p_X} (d_Y \chi) \wedge p_Y^\ast(A) + Z[\zeta]
\]

Hence \( \Pi[F, \zeta] \) remains invariant under the gauge transformation

\[
\chi \longrightarrow \chi + d_Y \tilde{\zeta}
\]

for any \( \tilde{\zeta} = \tilde{\zeta}_{abc} dx^{ab} \wedge dy^c \in \Lambda^3(M_X \times M_Y) \). Since the support of \( A \) can be made arbitrarily small \( d_Y \chi \) is uniquely specified by \( \Pi[F, \zeta] \). Furthermore

\[
d \star \Pi[F, \zeta] = -\int_{p_X} (d_X \star_X d_Y \chi) \wedge p_Y^\ast(A) + d \star Z[\zeta]
\]

hence \( d \star \Pi[F, \zeta] \) is invariant under the gauge transformation

\[
\chi \longrightarrow \chi + d_Y \tilde{\zeta} + \star_X d_X \tilde{\xi}
\]

for any \( \zeta = \zeta_{abc} dx^{ab} \wedge dy^c \) and \( \tilde{\zeta} = \tilde{\xi}_{abc} dx^a \wedge dy^{bc} \). Similarly \( d_X \star_X d_Y \chi \) is uniquely determined by \( d \star \Pi[F, \zeta] \).

In general, the permittivity functional \( \Pi \) is a non-local functional in spacetime given by the integral (8). If \( \chi \) is smooth, and not identically zero, then \( \Pi \) is always non-local. However for distributional susceptibility kernels it is possible for \( \Pi \) to remain local. In this category one has the local, linear Minkowski constitutive relations

\[
\Pi[F] = \epsilon_0 (\epsilon_r - 1) i_v F \wedge \bar{v} + \epsilon_0 (\mu_r^{-1} - 1) \ast ((i_v \ast F) \wedge F)
\]
where \( v \in \Gamma T M_Y \) is a vector field representing the bulk 4-velocity of the medium and 
\( \varepsilon_r, \mu_r \in \Gamma A^0 M_Y \) are the relative permittivity and permeability scalars of the medium. These
relations can be represented by a distributional susceptibility kernel with support on the 
diagonal set \( \{ (x, y) \in M_X \times M_Y | x = y \} \).

In general \( \Pi \) is said to be causal on all of \( M \) if \( \Pi|_x \) only depends of the values of \( F \) which lie on or within the past light-cone \( J^-(x) \subset M_Y \) of \( x \). If \( \Pi \) depends on \( \zeta \) it may
be causal on \( M^+_X \) if \( \Pi[F, \zeta]|_x \) only depends on the values of \( F \) and \( \zeta \) which lie on or within its
past light-cone \( J^-(x) \cap M^+_X \) of \( x \) and \( x \in M^+_X \). The data functional \( Z \) is casual on \( M^+_X \) if \( Z[\zeta]|_x \) depends only on \( \zeta \in \Sigma_{M_Y} \cap J^-(x) \) for all \( x \in M^+_X \). For \( \Pi \) to be causal on \( M^+_X \) it is
necessary and sufficient (lemma 5 in the appendix) that the following be satisfied:

- \( Z \) is causal on \( M^+_X \),
- \( (d_Y \chi)|_{(x,y)} = 0 \) for all \( (x, y) \in M^+_X \times M^+_Y \) such that \( y \notin J^-(x) \) and
- \( \iota_{\Sigma_{M_Y}}(\chi)|_{(x,y)} = 0 \) for all \( (x, y) \in M^+_X \times \Sigma_{M_Y} \) such that \( y \notin J^-(x) \), where \( \iota_{\Sigma_{M_Y}} : M^+_X \times \Sigma_{M_Y} \hookrightarrow M^+_X \times M^+_Y \) is the natural embedding.

A. Spacetime homogeneous constitutive relations for media in Minkowski spacetime

Minkowski spacetime has properties that underpin the notions of material spatial homogeneity and stationary processes. Being isomorphic to a real 4-dimensional vector space it can be given an affine structure in addition to its light-cone structure. Physically this implies that no particular point in a spacetime without gravitation has a distinguished status and the concepts of material and field energy, momentum and angular momentum can be defined in terms of the Killing symmetries of the spacetime metric. Since all points of the spacetime are equivalent relative to this affine structure it is sufficient to denote \( M_X \) and \( M_Y \) by \( M \) and, relative to any point chosen as origin, a point with coordinates \( x \) can be identified with a vector denoted by \( x \in \mathbb{R}^4 \). It is then convenient to introduce the Minkowski translation map \( A_z : M \to M, A_z(x) = x + z \) that maps points \( x \) to \( x + z \) on \( M \).

If the electromagnetic properties of an unbounded medium are independent of location in spacetime they will be called \textit{spacetime homogeneous}. Such electromagnetic constitutive
properties imply that variations in $F$ at event $y \in M$ produce an induced variation in a functional $\Pi_H[F]$ at event $x \in M$, via a kernel $\chi_{abcd}(x, y)$ that depends on the 4-vector $x - y$. If the constitutive relation is causal then there is no induced variation if $x \notin J^+(y)$. Furthermore in a spacetime homogeneous medium $Z[\zeta] = Z_H$ where $Z_H \in \Gamma\Lambda^2 M$ is independent of $\zeta$.

In terms of $A_z$ an electromagnetic constitutive functional $\Pi_H$ is given by

$$\Pi_H[F] = \int_{p_x}^{} \chi \land p_y(F) + Z_H$$

(11)

The functional $\Pi_H$ is said to be spacetime homogeneous if

$$\Pi_H[A_z F] = A_z \Pi_H[F]$$

(12)

This follows if the susceptibility kernel $\chi$ satisfies

$$\chi|_{(x+z, y+z)} = \chi|_{(x, y)}$$

(13)

and $A_z Z_H = Z_H$. The contribution $Z_H$ may model the presence of an externally prescribed stationary uniform permanent magnetic or electric polarization. Equation (13) implies the components of $\chi$ in (7) can be written

$$\chi_{abcd}(x, y) = X_{abcd}(x - y)$$

(14)

where

$$X_{abcd}(x) = \chi_{abcd}(x, 0)$$

(15)

Thus, in a Minkowski spacetime for materials with electromagnetic spacetime homogeneous properties, (8) can be written in terms of a convolution integral:

$$\Pi_H[F]_{ab}(x) = \frac{1}{4} \int_{y \in M} X_{abcd}(x - y) F_{ef}(y) d y^{cdef} + (Z_H)_{ab}$$

$$\equiv \frac{1}{4} \epsilon^{cdef} (X_{abcd} * F_{ef})(x) + (Z_H)_{ab}$$

(16)

where $\epsilon^{cdef} = \pm 1, 0$ denotes the Levi-Civita alternating symbol in coordinates in which the metric tensor takes the form $g = \eta_{ab} dx^a \otimes dx^b$ where $\eta_{ab} = \text{diag}(-1, +1, +1, +1)$. In these coordinates the $(Z_H)_{ab}$ are all constants.
Let \( \hat{F}_{ef}(k) \) and \( \hat{\Pi}_H[F]_{ab}(k) \) denote the Fourier transforms of \( F_{ef}(x) \) and \( \Pi_H[F]_{ab}(x) \) respectively, i.e.

\[
\hat{F}_{ef}(k) = \int_{x \in \mathbb{R}^4} F_{ef}(x) e^{ik \cdot x} dx_{0123}
\]

and

\[
\hat{\Pi}_H[F]_{ab}(k) = \int_{x \in \mathbb{R}^4} \Pi_H[F]_{ab}(x) e^{ik \cdot x} dx_{0123}
\]

where \( k = k_a dx^a \), \( k \cdot x = k_a x^a \). Similarly let \( \hat{X}_{a}^{ef}(k) \) be the Fourier transformation of \( \frac{1}{2} \epsilon^{cdef} X_{abcd}(x) \), i.e.

\[
\hat{X}_{abc}^{ef}(k) = \frac{1}{2} \epsilon^{cdef} \int_{x \in \mathbb{R}^4} X_{abcd}(x) e^{ik \cdot x} dx_{0123}
\]

If \( Z_H = 0 \) then it follows from (16) that:

\[
\hat{\Pi}_H[F]_{ab}(k) = \frac{1}{2} \hat{X}_{abc}^{cd}(k) \hat{F}_{cd}(k)
\]

Since \( \chi_{abcd} \) is a real function on \( M \) its Fourier transform satisfies

\[
\hat{X}_{abc}^{cd}(k)^* = \hat{X}_{abc}^{cd}(-k)
\]

The 36 components of \( \hat{X}_{abc}^{cd}(k) \) subject to this symmetry can be expressed in terms of permittivity, permeability and magneto-electric tensors relative to any observer frame. A specification of these components together with relations that determine the electric current \( J \) serve as an electromagnetic model for a spacetime homogeneous medium in Minkowski spacetime. If the medium lacks this electromagnetic homogeneity recourse to the Fourier transform (16) is not possible and the constitutive properties must be given in terms of a 2-point kernel and (8).

III. CONSTITUTIVE MODELS FOR A COLLISIONLESS IONIZED PLASMA

As noted in the introduction the computation of the susceptibility for homogeneous stationary dispersive media owes much to phenomenological models and input from experiment. For certain conductors, semi-conductors, insulators and low-dimensional structures much can also be learnt from the application of quantum theory. For inhomogeneous and anisotropic
media subject to non-stationary electromagnetic fields linear responses are often the subject of a perturbation approach. This is particularly so in the case of ionized gases.

As an application of the above formalism the classical linear response of a fully ionized inhomogeneous non-stationary collisionless plasma to a perturbation is considered in the presence of an arbitrary background gravitational field. The perturbed constitutive tensor will be calculated in terms of solutions to the classical Maxwell-Vlasov equations for the system. This system is described in terms of the electromagnetic 2-form $F \in \Gamma \Lambda^2 M^+$ over a gravitational spacetime $M^+$, lying in the future of an initial hypersurface $\Sigma_M$, and a collection of one-particle “distribution” forms (of degree 6), $\theta^{[\alpha]} \in \Gamma \Lambda^6 \mathcal{E}^+$ (one for each charged species of particle $[\alpha]$ with mass $m^{[\alpha]}$ and charge $q^{[\alpha]}$) on the upper unit hyperboloid bundle $\pi : \mathcal{E}^+ \to M^+$ over $M^+$. The 7-dimensional manifold $\mathcal{E}^+$ is a sub-bundle of the 8-dimensional tangent bundle $TM^+$ over $M^+$ whose sections are all future pointing time-like unit vector fields on $M^+$. Thus generic elements of $\mathcal{E}^+$ can be written $(z, w)$ with $z \in M^+$, $\pi(z, w) = z$ and $g(w, w) = -1$. The initial values of the one-particle forms are given on the hypersurface $\Sigma_\mathcal{E}$ where $\Sigma_\mathcal{E} = \pi^{-1}\{\Sigma_M\} \subset E^+$.

The Maxwell-Vlasov system is usually written in terms of the Maxwell system in vacuo and all sources are contained in the total current $J \in \Gamma TM^+$. This in turn is given by the sum over each species current

$$J = \sum_{[\alpha]} J^{[\alpha]}$$

(19)

where $J^{[\alpha]} \in \Gamma TM^+$. Thus in terms of $F$ and $J$ the Maxwell subsystem is

$$dF = 0 \quad \text{and} \quad \epsilon_0 d \star F = - \star \tilde{J}$$

(20)

The dynamic equations for each $\theta^{[\alpha]}$ can be written succinctly in terms of forms on $\mathcal{E}^+$ and a collection of Liouville vector fields $W^{[\alpha]} \in \Gamma T \mathcal{E}^+$ describing the flow of the charged particles associated with each species $[\alpha]$:

$$W^{[\alpha]}|_{(z, w)} = \mathcal{H}_{(z, w)}(z, w) + \frac{q^{[\alpha]}}{m^{[\alpha]}} \mathcal{V}_{(z, w)}(\bar{i}_{(z, w)} F)$$

(21)

in terms of certain horizontal and vertical lifts. With these vector fields the distribution forms $\theta^{[\alpha]}$ are defined to satisfy the collisionless conditions:

$$d\theta^{[\alpha]} = 0$$

(22)
and
\[ i_{W^{[\alpha]}} \theta^{[\alpha]} = 0 \]  
(23)

To close this system one requires:
\[ \star \tilde{J}^{[\alpha]} = q^{[\alpha]} \int \theta^{[\alpha]} \]
(24)

The closure of \( \theta^{[\alpha]} \) leads, from (25), to the continuity equation for each species current:
\[ d \star \tilde{J}^{[\alpha]} = d \left( \int \theta^{[\alpha]} \right) = \int d \theta^{[\alpha]} = 0 \]
(25)

so the total current 3-form \( \star \tilde{J} \) is closed away from the boundary \( \Sigma_M \).

A local coordinate system \((z_0, \ldots, z_3)\) for a region containing \( z \) on \( M^+ \) induces a local coordinate system \((z_0, \ldots, z_3, w^1, w^2, w^3)\) on \( \mathcal{E}^+ \). Since \( \mathcal{E}^+ \subset TM^+ \) the tangent vector for a generic element \((z, w) \in \mathcal{E}^+ \) may be written
\[ (z, w) = w^a \frac{\partial}{\partial z^a} \bigg|_{z} \in \mathcal{E}^+ \subset T_z M^+ \]
where \( \mathcal{E}^+_z = \pi^{-1}(\{z\}) \) is the 3-dimensional fibre of \( \mathcal{E}^+ \) over \( z \) coordinated by \((w^1, w^2, w^3)\) and \( w^0(z, w) \) is the solution to \( g_{ab} w^a w^b = -1 \) with \( w^0 > 0 \). All indices in the range 0, 1, 2, 3 are raised and lowered using \( g^{ab} \) and \( g_{ab} \) so that \( w_0 = w^a g_{a0} \). Given a pair of vectors \((z, w), (z, v) \in \mathcal{E}^+_z \subset T_z M^+ \) the horizontal lift of the vector \((z, v)\) to the point \((z, w) \in \mathcal{E}^+ \) will be denoted \( H_{(z, w)}(z, v) \in T_{(z, w)} \mathcal{E}^+ \) and is given by
\[ H_{(z, w)}(z, v) = \left( v^a \frac{\partial}{\partial z^a} + \Gamma^r_{ef}(z) w^e v^f \frac{\partial}{\partial w^r} \right) \bigg|_{(z, w)} \]
(26)
where \( \Gamma^r_{ef} \) are the Christoffel symbols determined by the metric components \( g^{ab} \). Furthermore if \( g(v, w) = 0 \) then the vertical lift of the vector \((z, v)\) to the point \((z, w) \in \mathcal{E}^+ \) is given by
\[ V_{(z, w)}(z, v) = \left( v^\mu \frac{\partial}{\partial w^\mu} \right) \bigg|_{(z, w)} \in T_{(z, w)} \mathcal{E}^+ \]
(27)

Thus from (21), each Liouville vector field in these coordinates can be expressed as
\[ W^{[\alpha]}|_{(z, w)} = w^a \frac{\partial}{\partial z^a} + \left( - \Gamma^w_{ef}(z) w^e w^f + \frac{q^{[\alpha]}}{m^{[\alpha]}} F_{ef}(z) g^{we} w^f \right) \frac{\partial}{\partial w^w} \]
(28)

Denote by \( \Omega \in \Gamma \Lambda^7 \mathcal{E}^+ \) the natural 7-form measure on \( \mathcal{E}^+ \) given in these coordinates by
\[ \Omega = \frac{|\det g|}{w_0} dz^{0123} \wedge dw^{123} \]
(29)
In ref. [11] eqn. (94) it is shown that for all species $[\alpha]$

$$dW_{[\alpha]}(\Omega) = 0 \quad (30)$$

The distribution function $f^{[\alpha]} \in \Gamma\Lambda^0\mathcal{E}^+$ relative to $\Omega$ for the species $[\alpha]$ is defined implicitly via

$$\theta^{[\alpha]} = i_{W^{[\alpha]}}(f^{[\alpha]}\Omega) \quad (31)$$

From (30, 31) it follows that (23) is equivalent to

$$W^{[\alpha]}(f^{[\alpha]}) = 0, \quad (32)$$

and from (24) the components of the species current $[\alpha]$ are given in terms of $f^{[\alpha]}(z, w)$ by

$$J^{[\alpha]b}(z) = q^{[\alpha]} \int \frac{w^b|\det(g)(z)|^{1/2}}{w_0(z, w)} f^{[\alpha]}(z, w) dw \quad (33)$$

A. Perturbation analysis

Let $\theta_1^{[\alpha]} \in \Gamma\Lambda^6\mathcal{E}^+$ and $F_1 \in \Gamma\Lambda^2\mathcal{M}^+$ be perturbations of $\theta_0^{[\alpha]}$ and $F_0$, i.e.

$$\theta^{[\alpha]} = \theta_0^{[\alpha]} + \theta_1^{[\alpha]} + \ldots \quad \text{and} \quad F = F_0 + F_1 + \ldots \quad (34)$$

where

$$d\theta_0^{[\alpha]} = 0, \quad i_{W_0^{[\alpha]}}\theta_0^{[\alpha]} = 0, \quad dF_0 = 0, \quad \epsilon_0 d \star F_0 = - \sum_{[\alpha]} q^{[\alpha]} \int \theta_0^{[\alpha]} \quad (35)$$

and

$$W_0^{[\alpha]}|_{(z,w)} = \mathcal{H}_{(z,w)}(z, w) + \frac{q^{[\alpha]}}{m^{[\alpha]}} \mathcal{V}_{(z,w)}(i_{(z,w)} F_0) \quad (36)$$

i.e. given by substituting $F = F_0$ into (28). Substituting $F$ into (21) yields $W^{[\alpha]} = W_0^{[\alpha]} + W_1^{[\alpha]} + \ldots$ where $W_1^{[\alpha]} = W_1^{[\alpha]}(F_1)$ and the map $\hat{W}_1 : \Gamma\Lambda^2\mathcal{M}^+ \to \Gamma\mathcal{T}\mathcal{E}^+$ is given by

$$\hat{W}_1^{[\alpha]}(F_1)|_{(z,w)} = \frac{q^{[\alpha]}}{m^{[\alpha]}} \mathcal{V}_{(z,w)}(i_{(z,w)} F_1) \quad (37)$$

The first order linear system for the perturbation $(\theta_1, F_1)$ is then

$$d\theta_1^{[\alpha]} = 0, \quad (38)$$

$$i_{W_0^{[\alpha]}}\theta_1^{[\alpha]} = -i_{W_1^{[\alpha]}(F_1)}\theta_0^{[\alpha]}, \quad (39)$$

$$dF_1 = 0, \quad (40)$$

$$\epsilon_0 d \star F_1 = - \sum_{[\alpha]} q^{[\alpha]} \int \theta_1^{[\alpha]} \quad (41)$$
FIG. 1. A segment of the solution curve \( C(x,v) \) to the unperturbed Lorentz force equation (46) with final position \( x \), final velocity \( (x,v) \), initial position \( y = C(x,v)(\tau) \) and initial velocity \( (y,u) = \dot{C}(x,v)(\tau) \).

Using (5) and (38) it follows that each species current in the sum on the right hand side of (41) is closed away from the initial hypersurface \( \Sigma_M \). In terms of the excitation field \( G_1 \in \Gamma \Lambda^2 M^+ \) equation (41) will be written

\[
d * G_1 = 0 \tag{42}
\]

where

\[
G_1 = \epsilon_0 F_1 + \Pi_1[F_1, \zeta_1] \tag{43}
\]

for some linear functional \( \Pi_1 \) of \( F_1 \) and \( \zeta \) such that

\[
d * \Pi_1[F_1, \zeta_1] = -\sum_{[a]} \int_{\pi} \theta^{[a]}_1 \tag{44}
\]

and \( \zeta_1 = \{\zeta_1^{[a]}, \zeta_1^{[a]}, \ldots\} \) where \( \zeta_1^{[a]} = \zeta_1^{[a]}|_{\Sigma} \zeta_1 \) for some \( \xi_1^{[a]} \in \Gamma \Lambda^5 \Sigma^+ \) which solves \( \theta_1^{[a]} = d\xi_1^{[a]} \).

Thus \( \xi_1^{[a]} \) is related to the initial velocity profile of the species \( [a] \).

In the next section III B the general susceptibility kernel \( \chi \in \Gamma \Lambda^0 (M_X^+ \times M_Y^+) \) and linear functional \( Z_1 \), determined by \( \theta_0^{[a]} \) and \( F_0 \), are found such that

\[
\Pi_1[F_1, \zeta_1]|_x = \int_{p_X} \chi \wedge p_Y(F_1) + Z_1[\zeta_1] \tag{45}
\]

satisfies (44).

B. A general formula for the functional \( \Pi_1 \) in an unbounded plasma

In this section a general expression for a susceptibility kernel will be constructed in terms of the integral curves of the vector field \( W_0^{[a]} \in \Gamma T \Sigma^+ \). Such curves describe segments of
particle world lines under the influence of the Lorentz force due to the external electromagnetic field $F_0$. Although, for a general $F_0$, it is not possible to derive an analytic form for such integral curves, special cases are amenable to an analytic analysis.

It proves convenient to let the final and initial states of each species of particle reside in fibres over $M^+_X$ and $M^+_Y$ respectively, bounded by the equivalent hypersurfaces $\Sigma_{M_X} \subset M^+_X$ and $\Sigma_{M_Y} \subset M^+_Y$. Thus the corresponding upper unit hyperboloid bundles $\pi_X : \mathcal{E}_X^+ \to M^+_X$ and $\pi_Y : \mathcal{E}_Y^+ \to M^+_Y$ with boundary hypersurfaces $\Sigma_{\mathcal{E}_X} \subset \mathcal{E}_X^+$ and $\Sigma_{\mathcal{E}_Y} \subset \mathcal{E}_Y^+$ are used to accommodate the final and initial 4-velocities of the particles. The generic elements of these bundles are written $(x, v) \in \mathcal{E}_X^+$ and $(y, u) \in \mathcal{E}_Y^+$ where $x \in M^+_X$, $y \in M^+_Y$ and $g(v, v) = g(u, u) = -1$. The induced coordinate systems for $\mathcal{E}_X^+$ and $\mathcal{E}_Y^+$ are $(x^0, \ldots, x^3, v^1, v^2, v^3)$ and $(y^0, \ldots, y^3, u^1, u^2, u^3)$. Let $v^0(x, v), v_0(x, v), u^0(y, u)$ and $u_0(y, u)$ be defined in the same way as $w^0(z, w)$ and $w_0(z, w)$.

The contribution to the tensor $\Pi_1[F_1, \zeta_1]$ due to all dynamic sources, arises from all particle histories in the past light cone of $x \in M^+_X$. The history of the species particle $[\alpha]$ which passes through event $x$ with 4-velocity $(x, v) \in \mathcal{E}_X^+$ will therefore be parametrized by negative proper time $\tau$: $C_{(x, v)}^{[\alpha]} : [\tau^0_0(x, v), 0] \to M^+$, $\tau \mapsto C_{(x, v)}^{[\alpha]}(\tau)$. Such a history is the unique solution to the Lorentz force equation

$$\nabla C_{(x, v)}^{[\alpha]} \dot{C}_{(x, v)}^{[\alpha]} = \frac{q^{[\alpha]}}{m^{[\alpha]}} (i \phi_{(x, v)}^{[\alpha]} F_0)$$

(46)

with

$$g(\dot{C}_{(x, v)}^{[\alpha]}, \dot{C}_{(x, v)}^{[\alpha]}) = -1$$

(47)

and final condition

$$C_{(x, v)}^{[\alpha]}(0) = x, \quad \dot{C}_{(x, v)}^{[\alpha]}(0) = (x, v)$$

(48)

where $\dot{C}_{(x, v)}^{[\alpha]}(\tau) = C_{(x, v)}^{[\alpha]}(\tau), (\partial_x)_{(x, v)} C_{(x, v)}^{[\alpha]}(\tau) = \dot{C}_{(x, v)}^{[\alpha]}(\tau) \frac{\partial}{\partial x}$ and the value $\tau^0_0(x, v) \leq 0$ solves

$$C_{(x, v)}^{[\alpha]}(\tau^0_0(x, v), v) \in \Sigma_{\mathcal{E}_Y}$$

(49)

This defines the prolongation of $C$, $\dot{C}_{(x, v)}^{[\alpha]} : [\tau^0_0(x, v), 0] \to \mathcal{E}_Y^+$. For each species $[\alpha], (x, v) \in \mathcal{E}_X^+$ and $\tau \in [\tau^0_0(x, v), 0]$ let $(y, u) \in \mathcal{E}_Y^+$ denote the initial state, i.e. $y = C_{(x, v)}^{[\alpha]}(\tau)$ and $(y, u) = \dot{C}_{(x, v)}^{[\alpha]}(\tau)$, see figure [1].

The family of all such histories is described in terms of the maps

$$\phi^{[\alpha]} : \mathcal{N}_{X}^+ \to \mathcal{E}_Y^+, \quad \phi^{[\alpha]}(\tau, x, v) = \dot{C}_{(x, v)}^{[\alpha]}(\tau)$$

(50)
where
\[ \mathcal{N}_X^{[\alpha]} = \{(\tau, x, v) \in \mathbb{R}^- \times E^+_X \mid \tau_0^{[\alpha]}(x, v) \leq \tau \leq 0\} \]

The manifold \( \mathcal{N}_X^{[\alpha]} \) with boundary is naturally a fibre bundle over \( E^+_X \) with projection \( \pi^{[\alpha]} : \mathcal{N}_X^{[\alpha]} \to E^+_X \), \((\tau, x, v) \mapsto \pi^{[\alpha]}(\tau, x, v) = (x, v)\) and for any form \( \alpha \in \Gamma^0 \mathcal{N}_X \) it follows from (4) that

\[
\int_{\pi^{[\alpha]}} \alpha = dx^I \wedge dy^I \int_0^0 \alpha^{(1)}(\tau, x, v) d\tau
\]

where \( \alpha = \alpha^{(1)}(\tau, x, v) dx^I \wedge dy^I \wedge d\tau + \alpha^{(2)}(\tau, x, v) dx^I \wedge d\tau \).

Let \( \Gamma \Lambda_5^5 E_Y^+ \) be the set of sections over \( \Sigma_{E_Y} \) with values in \( \Lambda^5 E_Y^+ \), i.e. if \( \alpha \in \Gamma \Lambda_5^5 E_Y^+ \) then for each \((y, u) \in \Sigma_{E_Y}, \alpha|_{(y, u)} \in \Lambda^5_{(y, u)} E_Y^+ \). Let the map \( \varphi^{[\alpha]} : \Gamma \Lambda_5^5 E_Y^+ \to \Gamma \Lambda^5 E_X^+ \) be given by

\[
\varphi^{[\alpha]}(\alpha)|_{(x, v)} = \phi^{[\alpha]}_{\pi^{[\alpha]}(x, v)}(\alpha|_{\pi^{[\alpha]}(x, v)}) \in \Lambda^5_{(x, v)} E_X^+ \quad (51)
\]

where \( \phi^{[\alpha]} : E_X^+ \to E^+ \), \( \phi^{[\alpha]}(x, v) = \phi(\tau, x, v) \). For each species \([\alpha]\) let the initial data be given by \( \zeta^{[\alpha]} \in \Gamma \Lambda_5^5 E_Y^+ \) with \( i_{W_{\alpha}} \zeta^{[\alpha]} = 0 \).

In terms of these maps, it will now be shown that the general polarization functional \( \Pi_1 \) on \( M_X^+ \) is given by

\[
\Pi_1[F_1, \zeta_1] = \sum_{[\alpha]} q^{[\alpha]} \int_{\pi_X} \int_{\pi_X^{[\alpha]}} \phi^{[\alpha]}(i_{\tilde{W}_{\alpha}}(F_1) \theta^{[\alpha]} + *d(\Xi_1(F_1)) + \sum_{[\alpha]} q^{[\alpha]} \int_{\pi_X} \varphi^{[\alpha]}(\zeta^{[\alpha]})) + *d(\tilde{Z}_1(\zeta_1)) \quad (52)
\]

where \( \Xi_1 \) and \( \tilde{Z}_1 \) are arbitrary linear functionals of \( F_1 \) and \( \zeta_1 \) respectively. The excitation \( \Pi_1[F_1, \zeta_1] \), in (52), is the general solution to (44) where the source \( \theta_1 \) satisfies (38, 39). The first two terms on the right hand side of (52) are linear functionals of \( F_1 \) whereas the last term is a linear functional of the initial data \( \zeta_1 \). Clearly \( *d(\Xi_1(F_1)) \) and \( *d(\tilde{Z}_1(\zeta_1)) \) are in the kernel of \( d* \), the homogeneous differential operator associated with (44).

The proof that (52) solves (44) requires the following lemma which is proved in the appendix.

**Lemma 1.** Let \( N \) be a manifold with a boundary \( \Sigma_N \subset N \) and let \( V \in \Gamma TN \) be a non-vanishing vector field on \( N \) such that every integral curve of \( V \) intersects \( \Sigma_N \) precisely once.
For each $\sigma \in N$ let the integral curve of $V$ terminating at $\sigma$ be given by $\gamma_\sigma : [\tau_0(\sigma), 0] \to N$ where $\gamma_0(0) = \sigma$ and $\gamma_0(\tau_0(\sigma)) \in \Sigma_N$. The set $\mathcal{N} = \{(\sigma, \tau) \subset \mathbb{R}^- \times N \mid \tau_{\min}(\sigma) \leq \tau \leq 0\}$ is a fibred manifold over $N$ with projection $\pi_N : \mathcal{N} \to N$, $(\tau, \sigma) \mapsto \pi_N(\tau, \sigma) = \sigma$. The family of integral curves of $V$ can be described by the map $\phi_N : \mathcal{N} \to N$, $\phi_N(\tau, \sigma) = \gamma_\sigma(\tau)$. 

Let $\zeta \in \Gamma \Lambda^p_{\Sigma_N} N$ such that $i_V \zeta = 0$, i.e. $\zeta$ is a $p$-form on $\Sigma_N$ with values in $\Lambda^p N$. Let $\varphi_N : \Gamma \Lambda^p_{\Sigma_N} N \to \Gamma \Lambda^p N$ be given by $\varphi_N(\zeta)|_\sigma = \phi^*_N(\tau_0(\sigma))(\zeta|_{\tau_0(\sigma)}) \in \Lambda^p_{\Sigma_N} N$.

If $\beta \in \Gamma \Lambda^p N$ is a $p$-form on $N$ with compact support such that $i_V \beta = 0$ and $\xi \in \Gamma \Lambda^p N$ has the form

$$\xi = \int_{\pi_N} \phi_N^*(\beta) \wedge d\tau + \varphi_N(\zeta)$$

then

$$i_V d\xi = \beta$$

and $\xi|_{\Sigma_N} = \zeta$.

This lemma is applied with $N = \mathcal{E}_X$, $\pi_N = \pi_X^{[\alpha]}$, $V = W_0^{[\alpha]}$, $\tau_0 = \tau_0^{[\alpha]}$, $\phi_N = \phi^{[\alpha]}$, $\varphi_N = \varphi^{[\alpha]}$, $\zeta = \zeta^{[\alpha]}$ and

$$\beta = -i_{\hat{W}_1^{[\alpha]}(F_1)} \theta_0^{[\alpha]}$$

Thus $\xi$ in (53) becomes the 5-form $\xi_1^{[\alpha]} \in \Gamma \Lambda^5 \mathcal{E}^{+}_X$,

$$\xi_1^{[\alpha]} = -\int_{\pi_X^{[\alpha]}} \phi^{[\alpha]}(i_{\hat{W}_1^{[\alpha]}(F_1)} \theta_0^{[\alpha]}) \wedge d\tau + \varphi^{[\alpha]}(\zeta_1^{[\alpha]}) = \int_{\pi_X^{[\alpha]}} d\tau \wedge \phi^{[\alpha]}(i_{\hat{W}_1^{[\alpha]}(F_1)} \theta_0^{[\alpha]}) + \varphi^{[\alpha]}(\zeta_1^{[\alpha]})$$

since $\deg (\phi^{[\alpha]}(i_{\hat{W}_1^{[\alpha]}(F_1)} \theta_0^{[\alpha]})) = 5$. In order to satisfy (38) let

$$\theta_1^{[\alpha]} = d\xi_1^{[\alpha]}$$

(57)

Furthermore from (54) and (55)

$$i_{\hat{W}_0^{[\alpha]}} \theta_1^{[\alpha]} = i_{\hat{W}_0^{[\alpha]}} d\xi_1^{[\alpha]} = -i_{\hat{W}_1^{[\alpha]}(F_1)} \theta_0^{[\alpha]}$$

so (39) is satisfied. In terms of $\xi_1^{[\alpha]}$ (52) can be written

$$\Pi_1[F_1, \xi_1]|_\sigma = \sum_{[\alpha]} q^{[\alpha]} \star \int_{\pi_X} \xi_1^{[\alpha]} + \star d(\Xi_1[F_1]|_\sigma) + \star d(\hat{Z}_1[\zeta_1])$$

16
Then from (5)

\[d \ast \Pi_1[F_1, \zeta_1] = d \ast \left(\sum_{[\alpha]} q^{[\alpha]} \int_{\pi_X} \zeta^{[\alpha]}_{1}\right)\]

\[= - \sum_{[\alpha]} q^{[\alpha]} d \int_{\pi_X} \zeta^{[\alpha]}_{1} = - \sum_{[\alpha]} q^{[\alpha]} d \int_{\pi_X} \theta^{[\alpha]}_{1}\]

Thus the Maxwell equation (44) is also satisfied. That (52) is the general solution to (44) follows from the fact that the difference between any two solutions of (44) satisfies the homogeneous differential equation associated with (44).

Thus we have succeeded in eliminating \(\theta^{[\alpha]}_{1}\) from the perturbation system (38-41), thereby reducing the system to \(dF_1 = 0\) and

\[\epsilon_0 d \ast F_1 + \frac{1}{2} \sum_{[\alpha]} q^{[\alpha]} d \int_{\pi_X} \int_{\pi^{[\alpha]}_X} d\tau \wedge \phi^{[\alpha]} (i \hat{W}^{[\alpha]}_1(F_1) \theta^{[\alpha]}_{0}) + \sum_{[\alpha]} q^{[\alpha]} d \int_{\pi_X} \phi^{[\alpha]} (\zeta^{[\alpha]}_{1}) = 0\]

(58)
in terms of \((\theta_0, F_0)\), for the perturbation \(F_1\). The perturbation \(\theta_1\) is then given by (57, 56).

C. The susceptibility kernel for an unbounded collisionless plasma

Equating (52) and (45) with the initial data

\[Z_1[\zeta_1] = \sum_{[\alpha]} q^{[\alpha]} \ast \int_{\pi_X} \phi^{[\alpha]} (\zeta^{[\alpha]}_{1}) + \ast d(\hat{Z}_1[\zeta_1])\]

(59)
yields

\[\int_{\pi_X} \chi \wedge p^*_Y(F_1) = \sum_{[\alpha]} q^{[\alpha]} \ast \int_{\pi_X} \int_{\pi^{[\alpha]}_X} d\tau \wedge \phi^{[\alpha]} (i \hat{W}^{[\alpha]}_1(F_1) \theta^{[\alpha]}_{0}) + \ast d(\hat{Z}_1[F_1])\]

(60)
Away from the initial hypersurface boundary \(\partial (M^+_X \times M^+_Y) = \Sigma M^+_X \times M^+_Y \cup M^+_X \times \Sigma M^+_Y\), using (5) and (A2) one has

\[\int_{\pi_X} \ast_X d_X \xi \wedge p^*_Y(F_1) = \int_{\pi_X} \ast_X d\xi \wedge p^*_Y(F_1) = \ast d \int_{\pi_X} \xi \wedge p^*_Y(F_1) = \ast d(\hat{\Xi}_1[F_1])\]

where \(\hat{\Xi}_1[F_1]\) is a linear functional of \(F_1\). The gauge freedom \(\chi \to \ast_X d_X \xi\) given in (10) is equivalent to the addition of the term \(\ast d(\hat{\Xi}_1[F_1])\) in (52).

If \(F_1\) is restricted to have support in a certain domain one may find \(\chi\) such that

\[\int_{\pi_X} \chi \wedge p^*_Y(F_1) = \sum_{[\alpha]} q^{[\alpha]} \ast \int_{\pi_X} \int_{\pi^{[\alpha]}_X} d\tau \wedge \phi^{[\alpha]} (i \hat{W}^{[\alpha]}_1(F_1) \theta^{[\alpha]}_{0})\]

(61)
To find such a susceptibility kernel requires the following maps.

For \((y, u) \in \mathcal{E}^+_Y\), let \(C_{(y,u)}^{[\alpha]} : \mathbb{R}^+ \to M^+\) and \(\dot{C}_{(y,u)}^{[\alpha]} : [0, \tau_{1}^{[\alpha]}(y, u)) \to \mathcal{E}^+\) be the unique solutions to the unperturbed Lorentz force equation (46,47) with initial conditions

\[
C_{(y,u)}^{[\alpha]}(0) = y \quad \text{and} \quad \dot{C}_{(y,u)}^{[\alpha]}(0) = (y, u)
\]

where \(\tau_{1}^{[\alpha]}(y, u) \in \mathbb{R}^+ \cup \{\infty\}\) is the supremum of the values of \(\tau\) such that \(C_{(y,u)}^{[\alpha]}(\tau) \in M\).

Let \(\Phi^{[\alpha]} : N_Y^{[\alpha]} \to M^+_X \times M^+_Y\),

\[
\Phi^{[\alpha]}(\tau, y, u) = \left( C_{(y,u)}^{[\alpha]}(\tau), y \right)
\]

where

\[
N_Y^{[\alpha]} = \left\{ (\tau, y, u) \in \mathbb{R}^+ \times \mathcal{E}^+_X \mid 0 \leq \tau < \tau_{1}^{[\alpha]}(y, u) \right\}
\]

This map gives the final and initial positions of a solution to the unperturbed Lorentz force equation in terms of the initial position, velocity and proper time parameter \(\tau \in [0, \tau_{1}^{[\alpha]}(y, u))\).

Observe that \(\Phi^{[\alpha]}\) is never surjective, since if \(\Phi^{[\alpha]}(\tau, y, u) = (x, y)\) then \(x \in J^+(y)\). Also \(\Phi^{[\alpha]}\) is never injective since \(\Phi^{[\alpha]}(0, y, u) = (y, y)\) for all \((y, u) \in \mathcal{E}^+_Y\). Thus \(\Phi^{[\alpha]}\) does not possess an inverse and one must work locally on \(M^+_X \times M^+_Y\) in order to establish the diffeomorphism \(\Psi^{[\alpha]} : \mathcal{D} \to \mathcal{D}'\),

\[
\Psi^{[\alpha]} = (\Phi^{[\alpha]}|_{\mathcal{D}'})^{-1}
\]

i.e.

\[
\Psi^{[\alpha]} \left( C_{(y,u)}^{[\alpha]}(\tau), y \right) = (\tau, y, u)
\]

with \(\mathcal{D} \subset M^+_X \times M^+_Y\) and \(\mathcal{D}' \subset N_Y^{[\alpha]}\) given by

\[
\mathcal{D} = \left\{ (x, y) \mid \text{There exists a unique } u \in \mathcal{E}_y \text{ and } \tau \in \mathbb{R}^+ \text{ such that } C_{(y,u)}^{[\alpha]}(\tau) = x \text{ for all } [\alpha] \right\}
\]

and

\[
\mathcal{D}' = \left\{ (\tau, y, u) \mid \Phi^{[\alpha]}(\tau, y, u) \in \mathcal{D} \text{ for all } [\alpha] \right\}
\]
This map $\Psi^{[\alpha]}$ encodes the solution to the two-point problem, namely given an initial event $y \in M_Y$ and final event $x \in M_X$ find the unique worldline to the unperturbed Lorentz force equation which passes through these two points. This worldline is specified by its initial velocity $(y, u) \in E^+_{\mathcal{X}}$ and its proper time $\tau$. The statement that $\Phi^{[\alpha]}$ does not have an inverse is equivalent to the statement that in general there may not be a unique solution to the two point problem on an arbitrary domain. The domain $\mathcal{D}$ is the set of all pairs $(x, y)$ such that there is a unique worldline.

Set

$$\chi = \sum_{[\alpha]} \chi^{[\alpha]}$$

where

$$\chi^{[\alpha]}|_{(x,y)} = \frac{1}{2} \frac{g^{[\alpha]}_{[\alpha]}}{m^{[\alpha]}} \star_X dy^{[\alpha]} \wedge i^{(y)}_{\alpha \beta \gamma \delta} \Psi^{[\alpha]} \left( d\tau \wedge \varpi^{[\alpha]} \left( g^\mu_{\nu\beta\gamma} u^\beta u_{\gamma} \theta^{[\alpha]}_{[\alpha]} \right) \right) |_{(x,y)}$$

for points $(x, y) \in \mathcal{D}$. In the appendix (lemma [6]) it is shown that given $x \in M^+_X$ [61] and $F_1$ with support in

$$\mathcal{D}_x = \mathcal{D} \cap p^{-1}_X \{ x \} = \{ y \in M_Y | (x, y) \in \mathcal{D} \}$$

then [61] holds at $x$. Furthermore although $(d_Y \chi)|_{(x,y)}$ is unique, $\chi$ has the gauge freedom given by [9].

One may write [67] implicitly as

$$\chi^{[\alpha]} \wedge p^+_Y \gamma = -q^{[\alpha]} \star_X S \Psi^{[\alpha]} \left( d\tau \wedge \varpi^{[\alpha]} \left( i^{(y)}_{\alpha \beta \gamma \delta} (i^{(y)}_{\alpha \beta \gamma \delta} \varpi^{[\alpha]} \theta^{[\alpha]}_{[\alpha]} ) \right) \right)$$

for all $\gamma \in \Gamma \Lambda^2 M^+_Y$ where $S: \Lambda^6_{(x,y)} (M^+_X \times M^+_Y) \to \Lambda^6_{(x,y)} (M^+_X \times M^+_Y)$,

$$S(\alpha) = i^{(y)}_{012345} \alpha \wedge dy^{012345}$$

The tensor projector $S$ has the simplest representation in the coordinate basis employed here since $i^a_{(y)} dy^b = \delta^b_a$.

From [64] for a chosen species $[\alpha]$ one must consider $\tau$ and $u$ to be functions of $(x, y)$ as well as the species label $[\alpha]$. Thus let $\Psi^{[\alpha]}$ be given by the functions $\tau = \tau(x, y)$ and $u^\mu = u^\mu(x, y)$, where we have dropped the species label, i.e. $\tau(x, y)$ and $u^\mu(x, y)$ solve the implicit equation

$$C^{[\alpha]}_{(y,u(x,y))} \left( \tau(x, y) \right) = x$$

19
where \( u^0(x,y) \) is the solution to \( u^a(x,y)u^b(x,y)g_{ab}(y) = -1 \) and \( u_0(x,y) = g_{a0}(y)u^a(x,y) \).

Let \( f_0^{[\alpha]} = f_0^{[\alpha]}(y,u) \) represent the unperturbed probability function on \( \mathcal{E}_Y^+ \). The contribution to the susceptibility kernel from species \([\alpha]\) is given in local coordinates by (lemma 7 in appendix.)

\[
\chi^{[\alpha]}|_{(x,y)} = -f_0^{[\alpha]} \frac{q^{[\alpha]}_0}{m^{[\alpha]}} |\det g|^{3/2} \frac{1}{4u_0} g^\mu_c u^b \epsilon^{dejk} \epsilon_{cbih} \epsilon_{\mu\nu\sigma} \times \\
\left( \frac{w^a}{2} \frac{\partial \tau}{\partial y^c} \frac{\partial u^\nu}{\partial x^d} \frac{\partial u^\sigma}{\partial x^e} - \frac{w^a}{2} \frac{\partial \tau}{\partial x^d} \frac{\partial u^\nu}{\partial y^c} \frac{\partial u^\sigma}{\partial x^e} + \frac{w^a}{2} \frac{\partial \tau}{\partial x^d} \frac{\partial u^\nu}{\partial x^e} \frac{\partial u^\sigma}{\partial y^c} \right) + \left( -\Gamma^\nu_{\mu} u^\mu u^f + \frac{q^{[\alpha]}_0}{m^{[\alpha]}} F_{0\mu} g^{\nu\rho} u^f \right) \frac{\partial \tau}{\partial x^d} \frac{\partial u^\rho}{\partial x^e} \right) dx_{jk} \wedge dy^{ih} \\
\] (72)

where \( g, F_0 \) and \( \Gamma^\nu_{\epsilon\mu} \) are all evaluated at \( y \in M^+_Y \) and each \( \tau \) and \( u \) belongs to the species \([\alpha]\). This is a key result of our article.

\[\text{D. A spacetime inhomogeneous microscopically neutral plasma.}\]

In a Vlasov model, a plasma or gas is deemed microscopically neutral if in its unperturbed state \( F_0 = 0 \). Let \( M \) be Minkowski spacetime with global Lorentzian coordinates so that \( \Gamma^\nu_{ab} = 0 \). Assume that \( f_0^{[\alpha]} \) solves the zeroth order Maxwell-Vlasov system (35) with \( \theta_0^{[\alpha]} = i W_0^{[\alpha]}(f_0^{[\alpha]}(X)) \) and \( F_0 = 0 \). In this scenario one can calculate \( \chi \) explicitly.

Since Minkowski spacetime is flat and \( F_0 = 0 \) the integral curves \( C_{(x,v)} \) in global Lorentzian coordinates are the straight lines:

\[
\tau = \sqrt{-g(x - y, x - y)} \quad \text{and} \quad u = \frac{(x - y)}{\tau} \\
\] (73)

Differentiating with respect to \( x^a \) and \( y^a \) gives.

\[
\frac{\partial \tau}{\partial x^a} = -u_a, \quad \frac{\partial \tau}{\partial y^a} = u_a, \quad \frac{\partial u^a}{\partial x^b} = \frac{(\delta^a_b + u_a u_b)}{\tau} \\
\text{and} \quad \frac{\partial u^a}{\partial y^b} = -\frac{(\delta^a_b + u_a u_b)}{\tau} \\
\] (74)

If follows from (72) that

\[
\chi^{[\alpha]}|_{(x,y)} = \frac{q^{[\alpha]}_0 f_0^{[\alpha]}(y,u)}{4u_0 \tau^2} g^{\mu_c u^b} \epsilon_{cbih} \left( 2dx_{0\mu} + \epsilon^{dejk} \epsilon_{\mu\nu\sigma} u^\nu u_d dx_{jk} \right) \wedge dy^{ih} \] (75)

where \( \tau(x,y) \) and \( u(x,y) \) are given by (73).
It is often useful to explore the response of an inhomogeneous plasma due to a monochromatic electromagnetic plane wave with constant amplitude $E$:

$$F_1 = Ee^{-i\omega x^0 + ikx^1} dx^{01}.$$  

(76)

Setting the initial hypersurface as $\Sigma_{\mathcal{E}_Y} = \{ y^0 = y_0^0 \}$, the general initial 5-form $\zeta_1^{[\nu]} \in \Gamma A_{\Sigma_{\mathcal{E}_Y}} \mathcal{E}_Y^+$ satisfying $i_{\mathcal{W}_0} \zeta_1^{[\nu]} = 0$ is given in terms of its components by

$$\zeta_1^{[\nu]}|_{(0,y^\mu,u^\nu)} = (u^0 dy^1 - u^1 dy^0) \wedge (\zeta_1^{[\nu]} dy^2 \wedge du^{123} + \zeta_1^{[\nu]} dy^3 \wedge du^{123}) + \zeta_1^{[\nu]} dy^{23} \wedge du^{123}$$

(77)

$$+ (u^0 dy^{123} - u^1 dy^{023})(\zeta_1^{[\nu]} du^{12} + \zeta_1^{[\nu]} du^{13} + \zeta_1^{[\nu]} du^{23})$$

where $\zeta_1^{[\nu]} = \zeta_1^{[\nu]}(y^\mu, u^\nu)$ for $A = 1, \ldots, 6$. For the integral curves $\zeta_1^{[\nu]}$ and the initial hypersurface $\Sigma_{\mathcal{E}_Y} = \{ y^0 = y_0^0 \}$ one has $\tau_0(x,v) = (y_0^0 - x^0)/v^0$ and the map $\varphi$ is given by $\phi^\tau(y^\mu) = x^\mu + \tau y^\mu$ and $\phi^\tau(u^\nu) = u^\nu$. From (45) with $\chi$ given by (75) and $Z_1[\zeta_1]$ given by (59) one has:

$$\Pi_1[F_1, \zeta_1] =$$

$$- \sum_{\nu} \frac{q^{[\nu]}}{m^{[\nu]}} E e^{-i\omega x^0 + ikx^1} \left\{ dx^{01} \int dv^{123} T^{[\nu]} \left( \frac{(v^0)^2}{v^0} - \left( \frac{v^1}{v^0} \right)^2 \right) + dx^{12} \int dv^{123} T^{[\nu]} v^2 \right. $$

$$- dx^{02} \int dv^{123} T^{[\nu]} \frac{v^2 v^1}{v^0} + dx^{13} \int dv^{123} T^{[\nu]} v^3 + dx^{03} \int dv^{123} T^{[\nu]} \frac{v^3 v^1}{v^0} \right\}$$

$$+ \sum_{\nu} \frac{q^{[\nu]}}{m^{[\nu]}} \left\{ dx^{02} \int dv^{123} \left( \zeta_1^{[\nu]} \frac{v^1(x^0 - y_0^0)}{v^0} - \zeta_1^{[\nu]} v^1 \right) + dx^{13} \int dv^{123} \left( \zeta_1^{[\nu]} v^1(x^0 - y_0^0) \right) \right.$$

$$+ dx^{23} \int dv^{123} \left( \zeta_1^{[\nu]} \frac{v^1 v^3(x^0 - y_0^0)}{(v^0)^2} - \zeta_1^{[\nu]} v^1 v^2 \frac{(x^0 - y_0^0)}{(v^0)^2} + \zeta_1^{[\nu]} \frac{(x^0 - y_0^0)}{v^0} \right) \right\} + *d(\Xi_1[F_1]) + *d(\tilde{Z}_1[\zeta_1])$$

(78)

where $\int dv^{123}$ denotes the triple integral operator $\int_0^\infty \int_0^\infty \int_0^\infty dv^{123}$, $v^0 = \sqrt{1 + v^\mu v^\mu}$,

$$T^{[\nu]} = T^{[\nu]}(x,v) = \int_{(y_0^0 - x^0)/v^0}^0 e^{i\tau(-\omega x^0 + kv^1)} f_0^{[\nu]}(x + \tau v, v) \tau d\tau$$

(79)

and $\zeta_1^{[\nu]} = \zeta_1^{[\nu]}(x^\mu, u^\nu) = \zeta_1^{[\nu]}(x^\mu - x_0^\mu/v^0, u^\nu)$ in (78). This response is not in general plane fronted.

For the particular case of a plane fronted plasma distribution:

$$f_0^{[\nu]}(x,v) = h_0^{[\nu]}(x^0, x^1, v^1) \delta(v^2) \delta(v^3)$$

(80)
with initial data:

\[ \zeta_1^{[\alpha]} = 0 \]  

(78) becomes the plane fronted 2-form

\[
\Pi_1[F_1, \zeta]_x = -dx^{01} \sum_{[\alpha]} \frac{g^{[\alpha]}}{m^{[\alpha]}} e^{-i\omega_0 x^0 + ik x^1} \int_{-\infty}^\infty \int_{0^0 - x^0}^0 d\tau e^{i\tau (-\omega_0 x_0 + k v^0)} h_0^{[\alpha]}(x^0 + \tau v^0, x^1 + \tau v^1, v^1) \frac{\tau}{v^0} + *d(\Xi_1[F_1])
\]

(81)

describing the response of a spacetime inhomogeneous unbounded plasma to (76).

E. Spacetime homogeneous unbounded plasmas

The previous discussion simplifies considerably if the unperturbed plasma is homogeneous in space and time. In Minkowski spacetime \( M \), an unbounded unperturbed plasma is deemed spacetime homogeneous if \( A_z F_0 = F_0 \) and \( \dot{A}_z \theta_0^{[\alpha]} = \theta_0^{[\alpha]} \) for all \( z \in M \) where the translation map \( A_z : M \to M, A_z(x) = x + z \) induces the map \( \dot{A}_z : \mathcal{E} \to \mathcal{E}, \dot{A}_z = A_z^* \).

Such spacetime homogeneity implies that in all inertial frames the medium is stationary and spatially homogeneous in all directions. Such a spacetime homogeneous plasma will give rise to a spacetime homogeneous electromagnetic constitutive relation. In addition to the components \((F_0)^{ab}\) with respect to an inertial frame being constant, the functions \(f^{[\alpha]}(x,v)\) are independent of event position \(x\) and can therefore be written \(f^{[\alpha]}(v)\).

In this scenario the Fourier transform (17) of the susceptibility kernel (18) for each species, is then given by

\[
\hat{\chi}^{[\alpha]}_{ab} e^{f(k)dx^{ab}} = \frac{1}{2} q^{[\alpha]} d\tau \int_{-\infty}^{0} d\tau \int dv^{123} f^{[\alpha]}_0(v) e^{-i k \cdot L^{[\alpha]} v} \frac{g^{\nu\rho} u^\rho - g^{\nu\rho} u^\rho}{v^\nu} \left( L^{[\alpha]} \beta(\tau) - \frac{\eta^{[\alpha]}}{u_0} L^{[\alpha]} 0 \beta(\tau) \right)
\]

(82)

where \( F_0 \) is the \( 4 \times 4 \) real matrix with components \((F_0)^{a}_{b} = \eta^{ac}(F_0)_{cb} \) generating the matrices

\[
D^{[\alpha]}_{ab} (\tau) = \exp \left( \tau \frac{q^{[\alpha]}}{m^{[\alpha]}} F_0 \right)^{a}_{b}, \quad D^{[\alpha]}_{ba} (\tau) = g_{bc} D^{[\alpha]}_{ca} (\tau) g^{da},
\]

\[
L^{[\alpha]}_{ab} (\tau) = \int_{0}^{\tau} D^{[\alpha]}_{ba}(\tau') d\tau', \quad L^{[\alpha]}_{ba} (\tau) = g_{bc} L^{[\alpha]}_{ca} (\tau) g^{da},
\]

(83)
\[ k \cdot \mathbf{L}^{[\alpha]} v = k_a \mathbf{L}^{[\alpha]} b(\tau) v^b \] and
\[ u^a(\tau, v^1, v^2, v^3) = D^{[\alpha]} a(\tau) v^b \] (84)

The susceptibility kernel (82) can be shown to agree with the results of O’Sullivan and Derfler12.

Furthermore for a microscopically neutral spacetime homogeneous plasma with \( F_0 = 0, G_1 = 0 \) and \( f_{\alpha 0}^0(v) = h_{\alpha 0}^0(v^1)\delta(v^2)\delta(v^3) \) it follows from (81) and (43) that for \( \text{Im}(\omega) > 0 \)
\[ 1 = \sum_{[\alpha]} \frac{q_{[\alpha]}^2}{m_{[\alpha]}^2} \int_{-\infty}^{\infty} \frac{h_{\alpha 0}^0(v^1) dv^1}{v^0(\omega v^0 + k v^1)^2} \] (85)
The relativistic Landau damped dispersion relation for plane fronted Langmuir modes in an unperturbed spacetime homogeneous plasma arises by analytic continuation of the integral (85) to the lower-half complex \( \omega \) plane.

F. Langmuir modes for an inhomogeneous unbounded plasma in Minkowski spacetime

If the plasma is microscopically neutral but spacetime inhomogeneous in its unperturbed state the Landau dispersion relation corresponding to (85) becomes more involved. We define the generalized Langmuir sector to contain perturbations described by (81) but with the external polarization specified by \( \Xi_1[F_1] \) set to zero. Since \( \zeta_{[\alpha]} = 0, \Pi_1[F_1, 0] \) will be denoted \( \Pi_1[F_1] \). Thus (43) with \( G_1 = 0 \) becomes
\[ \epsilon_0 F_1 = -\Pi_1[F_1] \] (86)

Consider the case where planar inhomogeneities in a plasma composed of electrons and ions arise from the unperturbed spacetime inhomogeneous solution to the Maxwell-Vlasov system: (35-36) with \( F_0 = 0 \) and
\[ f_{0}^{[\text{el}]}(x^0, x^1, x^2, x^3, v^1, v^2, v^3) = f_{0}^{[\text{ion}]}(x^0, x^1, x^2, x^3, v^1, v^2, v^3) \]
\[ = h\left(x^1 - \frac{v^1 x^0}{v^0}, v^1\right)\delta(v^2)\delta(v^3) \] (87)
where \( q^{[\text{el}]} = -q^{[\text{ion}]} \).

For example one might consider
\[ h(x^1, v^1) = n^{[\text{ion}]}(x^1) A^{[\text{ion}]}(x^1) \exp\left(-\frac{m^{[\text{ion}]} v^0}{k_B T^{[\text{ion}]}(x^1)}\right) \]
where $A^{\text{ion}}(x^1)$ normalizes (87). Then $f^{\text{ion}}$ initially at $x^0 = 0$ represents a distribution of ions where, at each spatial point $x^1$, the velocities belong to the 1-dimensional Maxwell-Jüttner distribution. In such a distribution the temperature $T^{\text{ion}}(x^1)$ and the number density of ions $n^{\text{ion}}(x^1)$ depend on position. It follows from (87) that $f^{\text{ion}}$ also initially represents a position dependent Maxwell-Jüttner distribution where $n^{\text{ion}}(x^1) = n^{\text{ion}}(x^1)$ and $T^{\text{ion}}(x^1) = T^{\text{ion}}(x^1)m^{\text{ion}}/m^{\text{ion}}$. After the initial moment, the ions and electrons drift according to (87) and velocities do not remain in the Maxwell-Jüttner distributions. Alternatively (87) might describe a plasma composed of particles and anti-particles.

In the theory of a spacetime homogeneous plasma $\omega$ and $k$ satisfy the transcendental dispersion relation (85). This relation contains an integral that is potentially singular. The Landau prescription circumvents this singularity by complexifying $\omega$ and defining an analytic continuation for the integral in the complex $\omega$ plane.

Setting $h_0^{\text{ion}}(x^0, x^1, v^1) = h(x^1 - v^1x^0/v^0, v^1)$ in (80) yields (87) and (81) becomes

\[
\Pi_1[F_1]|_x = -dx^{01} q^{\text{ion}}^2 \left( \frac{1}{m^{\text{ion}}} + \frac{1}{m^{\text{ell}}} \right) E e^{-i\omega x^0 + ikx^1} \int_{-\infty}^{\infty} dv^1 h(x^1 - \frac{v^1x^0}{v^0}, v^1) \int_0^\infty d\tau e^{i\tau(-\omega v^0 + kv^1)^2} \frac{\tau}{v^0} \tag{88}
\]

To compare with the results (85) given for the homogeneous case, consider the limit $y^0_0 \to -\infty$ with $\text{Im}(\omega) > 0$. Furthermore for the non-evanescent modes considered here $\text{Im}(k) = 0$. Thus (88) becomes

\[
\Pi_1[F_1]|_x = -dx^{01} \epsilon_0 Q^2_0 E e^{-i\omega x^0 + ikx^1} \int_{-\infty}^{\infty} dv^1 h(x^1 - \frac{v^1x^0}{v^0}, v^1) \frac{v^0(-\omega v^0 + kv^1)^2}{v^0(\omega v^0 + kv^1)^2} \tag{89}
\]

where

\[
Q^2_0 = \frac{q^{\text{ion}}^2}{\epsilon_0 m^{\text{ion}}} + \frac{q^{\text{ell}}^2}{\epsilon_0 m^{\text{ell}}}
\]

In a spacetime inhomogeneous plasma there is no time-harmonic solution or associated transcendental dispersion relation between $\omega$ and $k$. We therefore propose solving (86) with a longitudinal field $F_1$ represented as the packet

\[
F_1(x^0, x^1) = dx^{01} \int_{-\infty}^{\infty} d\tilde{\omega} \int_{-\infty}^{\infty} d\tilde{k} \tilde{E}(\tilde{\omega}, \tilde{k}) e^{-i\tilde{\omega} x^0 + ikx^1} \tag{90}
\]

24
Substituting (89) and (90) into (86) yields

\[ \int_{-\infty}^{\infty} d\tilde{\omega} \int_{-\infty}^{\infty} d\tilde{k} \hspace{1pt} \hat{E} (\tilde{\omega}, \tilde{k}) e^{-i\tilde{\omega}x^0 + i\tilde{k}x^1} \]

\[ = \mathcal{Q}_0^2 \int_{-\infty}^{\infty} d\tilde{\omega} \int_{-\infty}^{\infty} d\tilde{k} \hspace{1pt} \hat{E} (\tilde{\omega}, \tilde{k}) e^{-i\tilde{\omega}x^0 + i\tilde{k}x^1} \int_{-\infty}^{\infty} dv^1 \frac{h(x^1 - v^1x^0/v^0, v^1)}{v^0(\hat{\omega}v^0 + k^1)^2} \]

Performing the inverse Fourier transform gives

\[ 4\pi^2 \hat{E}(\omega, k) \]

\[ = \mathcal{Q}_0^2 \int_{-\infty}^{\infty} dx^0 \int_{-\infty}^{\infty} dx^1 \int_{-\infty}^{\infty} d\tilde{\omega} \int_{-\infty}^{\infty} d\tilde{k} \hspace{1pt} \hat{E} (\tilde{\omega}, \tilde{k}) e^{i(\tilde{\omega} - \omega)x^0 + (\tilde{k} - k)x^1} \int_{-\infty}^{\infty} dv^1 \frac{h(x^1 - v^1x^0/v^0, v^1)}{v^0(\hat{\omega}v^0 + k^1)^2} \]

Since

\[ \int_{-\infty}^{\infty} dx^0 \int_{-\infty}^{\infty} dx^1 e^{i(\tilde{\omega} - \omega)x^0 + (\tilde{k} - k)x^1} h(x^1 - v^1x^0/v^0, v^1) = 2\pi \delta(k - \tilde{k}) \delta(\omega - \omega + v^1(k - \tilde{k})/v^0) \]

where

\[ \hat{h}(k, v^1) = \int_{-\infty}^{\infty} e^{-iks} h(s, v^1) ds \]

one has

\[ \hat{E}(\omega, k) = \frac{\mathcal{Q}_0^2}{2\pi} \int_{-\infty}^{\infty} d\tilde{\omega} \int_{-\infty}^{\infty} d\tilde{k} \int_{-\infty}^{\infty} dv^1 \frac{\hat{E}(\tilde{\omega}, \tilde{k})}{v^0(\hat{\omega}v^0 + k^1)^2} \delta(k - \tilde{k}) \delta(\omega - \omega + v^1(k - \tilde{k})/v^0) \]

(91)

Since we restrict to non-evanescent modes \( k \) and \( \tilde{k} \) are real. For \( \hat{E}(\omega, k) \) to be non-zero one requires the argument of the \( \delta \)-function to be zero. Since \( v^1 \) is real and therefore \( v^1(k - \tilde{k})/v^0 \) is real it follows that although \( \text{Im}(\omega) > 0 \) and \( \text{Im}(\tilde{\omega}) > 0 \) the difference \( \omega - \tilde{\omega} \) is real. Furthermore from \( \tilde{\omega} - \omega + v^1(k - \tilde{k})/v^0 = 0 \) it follows that \( |\tilde{\omega} - \omega| < |\tilde{k} - k| \). Thus (91) becomes

\[ \hat{E}(\omega, k) = \frac{\mathcal{Q}_0^2}{2\pi} \int_{-\infty}^{\infty} d\tilde{k} \hspace{1pt} I(\omega, k, \tilde{k}) \]

(92)

where

\[ I(\omega, k, \tilde{k}) = \int_{S(\omega, k, \tilde{k})} \hspace{1pt} d\tilde{\omega} \hspace{1pt} \hat{E}(\tilde{\omega}, \tilde{k}) \frac{(k - \tilde{k})}{(\tilde{\omega}k - k\omega)^2} \delta\left(k - \tilde{k}, \frac{k - \tilde{k}}{\sqrt{(k - \tilde{k})^2 - (\tilde{\omega} - \omega)^2}}\right) \]

(93)

and the contour of integration for \( \tilde{\omega} \) in (93) is the straight line \( S(\omega, k, \tilde{k}) \) where \( \text{Im}(\tilde{\omega}) = \text{Im}(\omega) > 0 \) and \(-|\tilde{k} - k| < \text{Re}(\tilde{\omega} - \omega) < |\tilde{k} - k| \). Since \((\tilde{\omega} - \omega)^2 < (k - \tilde{k})^2 \) the arguments of \( \hat{h} \) in (93) are always real and non-singular on \( S(\omega, k, \tilde{k}) \).
FIG. 2. The upper contour denotes $S(\omega, k, \hat{k})$ when $\text{Im}(\omega) > 0$ for real $k, \hat{k}$. The lower contour of integration is used when $\text{Im}(\omega) < 0$ for real $k, \hat{k}$.

FIG. 3. Branch cuts in $\omega$ for $I(\omega, k, \hat{k})$.

To accommodate the situation when $\hat{E}(\omega, k)$ describes damped electromagnetic waves one must continue to $\text{Im}(\omega) < 0$ for real $k$. However there is a double pole in the complex $\hat{\omega}$ plane at $\hat{\omega} = \hat{\omega}_0 = \hat{k}\omega/k$ that coincides with $S(\omega, k, \hat{k})$ when $\text{Im}(\omega) = 0$ and $|\omega| < |k|$. To define an analytic continuation of to $\text{Im}(\omega) < 0$ when $|\text{Re}(\omega)| < |k|$, we indent $S(\omega, k, \hat{k})$ to encircle the pole in the standard manner and write the contour integral in terms of a principle part and associated residue, see figure 2. Such a continuation scheme gives rise to branches in the $\omega$ plane for $I(\omega, k, \hat{k})$ as shown in figure 3.
This analytic continuation of (93) to \( \text{Im}(\omega) < 0 \) acquires the residue

\[
R(\omega, k, \hat{k}) = \frac{|k - \hat{k}|}{k |k|} \frac{\partial \hat{E}}{\partial \omega} \left( \frac{\omega \hat{k}}{k}, \hat{k} \right) \hat{h}\left( k - \hat{k}, \frac{s_k s_{k-k} \omega}{\sqrt{k^2 - \omega^2}} \right) - \frac{k}{(k^2 - \omega^2)^{3/2}} \hat{E}\left( \frac{\omega \hat{k}}{k}, k \right) \hat{h}_v\left( k - \hat{k}, \frac{s_k s_{k-k} \omega}{\sqrt{k^2 - \omega^2}} \right)
\]

where \( \hat{h}_v(k, v^1) = \frac{\partial \hat{h}}{\partial v^1}(k, v^1) \), \( s_k = k/|k| \) and \( s_{k-k} = (k - \hat{k})/|k - \hat{k}| \). In the case when \( \text{Im}(\omega) = 0 \), the principle value of (93) is taken together with residue \( \frac{1}{2} R(\omega, k, \hat{k}) \). Equation (92) then gives

\[
\hat{E}(\omega, k) = \frac{k}{2\pi} \int_{-\infty}^{\infty} I(\omega, k, \hat{k}) \, d\hat{k} \quad \text{if} \quad \text{Im}(\omega) > 0 \quad \text{or} \quad |\text{Re}(\omega)| > |k|
\]

\[
\hat{E}(\omega, k) = \frac{k}{2\pi} \int_{-\infty}^{\infty} I(\omega, k, \hat{k}) \, d\hat{k} - i k \int_{-\infty}^{\infty} R(\omega, k, \hat{k}) \, d\hat{k} \quad \text{if} \quad \text{Im}(\omega) < 0 \quad \text{and} \quad |\text{Re}(\omega)| \leq |k|
\]

\[
\hat{E}(\omega, k) = \frac{k}{2\pi} \int_{-\infty}^{\infty} \mathcal{P} I(\omega, k, \hat{k}) \, d\hat{k} - i k \int_{-\infty}^{\infty} R(\omega, k, \hat{k}) \, d\hat{k} \quad \text{if} \quad \text{Im}(\omega) = 0 \quad \text{and} \quad |\text{Re}(\omega)| < |k|
\]

where \( \mathcal{P} I(\omega, k, \hat{k}) \) in (94) refers to the principle part of (93) when \( \text{Im}(\omega) = 0 \) and \( |\text{Re}(\omega)| < |k| \) and hence the pole at \( \tilde{\omega}_0 \) lies on the contour \( S(\omega, k, \hat{k}) \). Thus in each domain above, the perturbation \( \hat{E}(\omega, k) \) must be determined by solving a non-standard integral equation.

\section*{IV. CONCLUSIONS}

In this article a classical covariant description of electromagnetic interactions in continuous matter in an arbitrary background gravitational field has been formulated in terms of a polarization 2-form that enters into the macroscopic Maxwell equations. Linear dispersive constitutive relations arise when this 2-form is expressed as an affine functional of the Maxwell 2-form with the aid of a 2-point susceptibility kernel. We have explored the constraints on this kernel imposed by causality requirements, spacetime Killing symmetries and local gauge freedoms. The formalism has been applied to an analysis of constitutive models for waves in collisionless plasmas. In particular a formula for the linear susceptibility of a fully ionized inhomogeneous unbounded non-stationary collisionless plasma to a perturbation in the presence of gravity has been given in terms of maps describing the dynamics.
of the plasma. This formula has been elucidated by reference to both homogeneous and
inhomogeneous perturbations in Minkowski spacetime. In the former case one recovers the
standard Landau dispersion relation when perturbing Langmuir modes. In the latter case
we have described a generalized damping mechanism for such modes that may arise when
the unperturbed state is both inhomogeneous and non-stationary. Such a mechanism arises
from the analytic continuation of an integral equation that replaces the Landau dispersion
relation.

It is concluded that the use of a covariant 2-point affine susceptibility kernel in describ-
ing the electromagnetic response of dispersive media offers a modelling tool that naturally
generalizes the use of permittivity and permeability tensors used to model electromagnetic
interactions in non-relativistic media. The formulation in terms of an arbitrary background
spacetime metric offers potential applications in a number of astrophysical contexts involving
electromagnetic fields in inhomogeneous or non-stationary plasmas

**Lemma 2.** *Local representation of $\int_{\Sigma^N} \alpha$ in (4) from the implicit definition in equation (3).*

**Proof.** On a fibred manifold $\mathcal{N}$ of dimension $n + r$ with projection $\pi_{\mathcal{N}} : \mathcal{N} \to N$ over a manifold $N$ of dimension $n$. Thus at each point $\sigma \in N$ one has the fibre $\mathcal{N}_\sigma = \pi_{\mathcal{N}}^{-1}\{\sigma\} = \{(\sigma', \varsigma) \in \mathcal{N} | \pi_{\mathcal{N}}(\sigma', \varsigma) = \sigma\}$ so dim($\mathcal{N}_\sigma$) = $r$ is the fibre dimension. Let $(\sigma^1, \ldots, \sigma^n)$ and $(\sigma^1, \ldots, \sigma^n, \varsigma^1 \ldots \varsigma^r)$ be local coordinates for patches on $N$ and $\mathcal{N}$ respectively.

Consider first the case when $\alpha \in \Gamma^{p+r}\mathcal{N}$ consists of a single component $\alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^{1 \ldots r}$ with no sum on $I$. Hence explicit summation will be used in this particular proof. Set $\hat{I} = \{1, \ldots, n\}\setminus I$ so that $d\sigma^{\hat{I}} \wedge d\sigma^I = \pm d\sigma^{1 \ldots n}$ and let $\beta = \sum_J \beta_J(\sigma)d\sigma^J$ then $\beta \wedge d\sigma^I =$
\[ \pm \beta_I \alpha_I d\sigma^{1-n} \text{ so that:} \]

\[
\sum_J \int_{(\sigma, \varsigma) \in N} \pi_N^*(\beta_J(\sigma)d\sigma^J) \wedge \alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^{1-r} \]

\[ = \sum_J \int_{(\sigma, \varsigma) \in N} \beta_J(\sigma)d\sigma^J \wedge \alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^{1-r} \]

\[ = \sum_J \int_{(\sigma, \varsigma) \in N} \beta_J(\sigma)d\sigma^J \wedge d\sigma^I \wedge \alpha_I(\sigma, \varsigma)d\varsigma^{1-r} \]

\[ = \int_{(\sigma, \varsigma) \in N} \beta_I(\sigma)d\sigma^I \wedge d\sigma^I \wedge \alpha_I(\sigma, \varsigma)d\varsigma^{1-r} \]

\[ = \int_{\sigma \in N} \beta_I(\sigma)d\sigma^I \wedge \alpha_I(\sigma, \varsigma)d\varsigma^{1-r} \]

Thus by linearity

\[ \int_N \pi_N^*(\beta) \wedge \alpha = \sum_I \int_{\sigma \in N} \beta \wedge d\sigma^I \int_{\varsigma \in N} \alpha_I(\sigma, \varsigma)d\varsigma^{1-r} \]  

(A1)

where \( \alpha = \sum_I \alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^{1-r} \). If (A1) holds then for \( \alpha = \sum_I \alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^{1-r} \),

\[ \int_N \beta \wedge \int_{\pi_N^*} \alpha = \sum_I \int_N \beta \wedge d\sigma^I \int_{\varsigma \in N} \iota_I^*(\sigma) \alpha|_{(\sigma, \varsigma)} = \sum_I \int_N \beta \wedge d\sigma^I \int_{\varsigma \in N} \alpha_Id\varsigma^{1-r} \]

\[ = \int_N \pi_N^*(\beta) \wedge \alpha \]

Hence (3). Conversely if (3) holds for \( \alpha = \sum_I \alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^{1-r} \) then from (A1)

\[ \int_N \beta \wedge \int_{\pi_N^*} \alpha = \int_N \pi_N^*(\beta) \wedge \alpha = \sum_I \int_N \beta \wedge d\sigma^I \int_{\varsigma \in N} \iota_I^*(\sigma) \alpha|_{(\sigma, \varsigma)} \]

Since this is true for all \( \beta \) then (A1) holds.

If \( \alpha \) does not contain the factor \( \varsigma^{1-r} \) i.e. \( \alpha = \alpha_I(\sigma, \varsigma)d\sigma^I \wedge d\varsigma^K \) where \( K \neq \{1, \ldots, r\} \)

then the right hand side of (3) becomes

\[ \int_N \pi_N^*(\beta) \wedge \alpha = \sum_J \int_N \beta_J \alpha_I(\sigma, \varsigma)d\sigma^J \wedge d\sigma^I \wedge d\varsigma^K = 0 \]

and the right hand side of (4) becomes

\[ \sum_I d\sigma^I \int_{\varsigma \in N} \alpha_{IK}(\sigma, \varsigma)d\varsigma^K = 0 \]

Thus by linearity (3) and (4) are equivalent for all \( \alpha \). \qed
Lemma 3. Verification of equation (5):

\[ \left( d\int_{\pi_N} \alpha \right)_{|\sigma} = \left( \int_{\pi_N} d\alpha \right)_{|\sigma} \]

Proof. Let \( \deg(\alpha) = p + r \), \( \deg(\beta) = n - p - 1 \) and \( \partial N \) and \( \partial N' \) be the boundaries of \( N \) and \( N' \). Since \( \sigma \notin \partial N \) one may choose \( \beta \) to have support away from \( \partial N \) thus

\[ \int_{\partial N} \beta \wedge \left( \int_{\pi_N} \alpha \right) = 0 \]

and since \( \alpha \) has support away from \( \partial N \) then

\[ \int_{\partial N} \pi_N^* \beta \wedge \alpha = 0 \]

It follows that

\[ \int_{N} \beta \wedge \left( \int_{\pi_N} d\alpha \right) = \int_{N} \pi_N^* (\beta) \wedge d\alpha \]

\[ = (-1)^{n-p-1} \int_{N} d(\pi_N^* (\beta) \wedge \alpha) + (-1)^{n-p} \int_{N} d\pi_N^* (\beta) \wedge \alpha \]

\[ = (-1)^{n-p-1} \int_{\partial N} \pi_N^* (\beta) \wedge d\alpha + (-1)^{n-p} \int_{N} \pi_N^* (d\beta) \wedge \alpha \]

\[ = (-1)^{n-p} \int_{N} d\beta \wedge \left( \int_{\pi_N} \alpha \right) \]

\[ = (-1)^{n-p} \int_{N} \beta \wedge d\left( \int_{\pi_N} \alpha \right) \]

\[ = (-1)^{n-p} \int_{\partial N} \beta \wedge \left( \int_{\pi_N} \alpha \right) + \int_{N} \beta \wedge d\left( \int_{\pi_N} \alpha \right) \]

\[ = (-1)^{n-p} \int_{N} \beta \wedge d\left( \int_{\pi_N} \alpha \right) \]

\[ = \int_{N} \beta \wedge d\left( \int_{\pi_N} \alpha \right) \]

Lemma 4. Proof of

\[ \int_{px} \ast_x \alpha = \ast \int_{px} \alpha \] (A2)

Proof. The only non-trivial \( \alpha \in \Gamma \Lambda (M_X \times M_Y) \) in (A2) can be written \( \alpha = \alpha_1 dx^I \wedge dy^{0123} \). Then

\[ \int_{px} \ast_x (\alpha_1 dx^I \wedge dy^{0123}) = \int_{px} \alpha_1 (\ast dx^I) \wedge dy^{0123} = \ast dx^I \int_{M_X} \alpha_1 dy^{0123} = \ast \int_{px} \alpha_1 dx^I \wedge dy^{0123} \]

\[ \square \]
Lemma 5. \( \Pi \) is causal on \( M_X^\pm \) if and only if

- \( Z \) is causal on \( M_X^\pm \),
- \( (dY\chi)|_{(x,y)} = 0 \) for all \( (x,y) \in M_X^\pm \times M_Y^\pm \) such that \( y \notin J^-(x) \) and
- \( i_{\Sigma_M}^*(\chi)|_{(x,y)} = 0 \) for all \( (x,y) \in M_X^\pm \times \Sigma_M \) such that \( y \notin J^-(x) \), where\( i_{\Sigma_M} : M_X^\pm \times \Sigma_M \rightarrow M_X^\pm \times \Sigma_M \) is the natural embedding.

Proof. If \( i_{\Sigma_M} : \Sigma_M \rightarrow M_Y^\pm \) is the natural embedding then \( i_{ab}^* i_{\Sigma_M}^* \chi|_{(x,y)} = i_{\Sigma_M}^* i_{ab}^* \chi|_{(x,y)} \), and

\[
\int_{y \in M_Y^\pm} i_{ab}^* (\chi \wedge p_Y^*(dA)|_y) = \int_{y \in M_Y^\pm} i_{ab}^* (\chi \wedge dY(p_Y^*A)|_y) = \int_{y \in M_Y^\pm} i_{ab}^* (dY\chi \wedge p_Y^*A)|_y = \int_{y \in \Sigma_M} i_{ab}^* i_{\Sigma_M}^* (\chi \wedge p_Y^*A)|_y = \int_{y \in \Sigma_M \cap \Sigma_M \cap J^-} i_{ab}^* (dY\chi \wedge p_Y^*A)|_y = 0
\]

First one argues that (A3) implies that \( \Pi \) is causal on \( M_X^\pm \). Given \( x \in M_X^\pm \) and \( F_1, F_2 \in \Gamma \Lambda^2 M_Y^\pm \) such that \( F_1|_y = F_2|_y = 0 \) for \( y \in J^- \), set \( F = F_1 - F_2 \) so that \( F = 0 \) on \( J^- \). Since \( M_Y^\pm \) is topologically trivial \( F \) is exact, \( F = d\hat{A} \), and hence \( d\hat{A} = 0 \) on \( J^- \). Then since \( J^- \) is topologically trivial there exists \( f \in \Gamma \Lambda^0 M_Y^\pm \) such that \( \hat{A} = df \) on \( J^- \). Thus one can choose a gauge \( A = \hat{A} - df \) so that \( A = 0 \) on \( J^- \). Given \( \zeta \) such that \( \zeta|_y = 0 \) for \( y \in J^- \cap \Sigma_M \) then \( Z[\zeta]|_x = 0 \) since \( Z \) is causal. Thus from (A4)

\[
\Pi[F, \zeta]_{ab}(x) = \int_{y \in M_Y^\pm} i_{ab}^* (\chi \wedge p_Y^*(dA)|_y) = \int_{y \in \Sigma_M \cap \Sigma_M \cap J^-} i_{ab}^* i_{\Sigma_M}^* (\chi \wedge p_Y^*A)|_y = \int_{y \in \Sigma_M \cap \Sigma_M \cap J^-} i_{ab}^* (dY\chi \wedge p_Y^*A)|_y = 0
\]
Thus \( \tau \) and one may write \( (\cdot) \). Given \( \text{Proof of lemma 1.} \)

One can now prove \( \text{lemma 1} \) in section \( \text{III B} \).

\[ 0 = \Pi[F, \zeta]_{ab}(x) \]

\[ = \int_{y \in \Sigma_{M^r \setminus \delta J^-(x)}} i_{ab}^*(\chi(x,y) \wedge p_{Y}^* A|_y)|_{(x,y)} \]

\[ - \int_{y \in M^r \setminus \delta J^-(x)} i_{ab}^*(dy \chi(x,y) \wedge p_{Y}^* A|_y)|_{(x,y)} \]

\[ (A5) \]

The 4-dimensional domain \( M^r \setminus \delta J^-(x) \) denotes points outside the backward lightcone of \( x \), while the 3-dimensional domain \( \Sigma_{M^r \setminus \delta J^-(x)} \) denotes the points on \( \Sigma_{M^r} \) that are not causally connected to \( x \). Choosing such an \( A \) to have support about a small neighbourhood of \( y \in M^r \setminus \delta J^-(x) \setminus \Sigma_{M^r} \) results in the first term of \( (A5) \) being zero and thus \( (dy \chi)|_{(x,y)} = 0 \). Likewise setting \( A \) to have support about a small neighbourhood of \( y \in \Sigma_{M^r \setminus \delta J^-(x)} \) implies \( i_{ab}^*(\chi)|_{(x,y)} = 0 \).

One can now prove \( \text{lemma 1} \) in section \( \text{III B} \).

**Proof of lemma 1.** Given \( \sigma \in N \), with \( V \) non vanishing there exists a coordinate system \( (\sigma^1, \ldots, \sigma^n) \) on \( N \) adapted to \( V \) so that \( V = \frac{\partial}{\partial \sigma^I} \) and the image of the curve \( \gamma_\sigma : [\tau_0(\sigma), 0] \rightarrow N \) is contained in the coordinate patch. Write \( \beta = \beta_I d\sigma^I \) then since \( i_V \beta = 0 \) the sum is over \( I \in \{2, \ldots, n\} \). With \( \sigma^I \) distinguished write \( \beta_I(\sigma) = \beta_I(\sigma^1, \sigma^I) \) where \( \sigma = (\sigma^2, \ldots, \sigma^n) \). Also since \( i_V \beta = 0, \beta|_{(\sigma^1, \sigma^I)} = \beta_I(\sigma^1, \sigma^I) d\sigma^I \). Likewise since \( i_V \zeta = 0 \) one has \( \zeta|_{\sigma^0} = \zeta_I(\sigma_0) d\sigma^I \).

Solving for the integral curves of \( V \) gives \( \phi_N(\tau, \sigma^1, \sigma^I) = (\tau + \sigma^1, \sigma^I) \)

and one may write \( \tau_0(\sigma^1, \sigma) = \tau_0(\sigma) - \sigma^1, \) giving

\[ \varphi_N(\zeta)|_{(\sigma^1, \sigma)} = \phi_{N, \tau_0(\sigma^1, \sigma)}(\zeta|_{\tau_0(\sigma)}) = \zeta_I(\tau_0(\sigma), \sigma) d\sigma^I \]

Thus

\[ \xi|_{(\sigma^1, \sigma)} = \int_{\tau = \tau_0(\sigma) - \sigma^1} \phi_N^*(\beta) \wedge d\tau + \varphi_N(\zeta) \]

\[ = \left( \int_{\tau = \tau_0(\sigma) - \sigma^1} \beta_I(\sigma^1 + \tau, \sigma) d\tau + \zeta_I(\tau_0(\sigma), \sigma) \right) d\sigma^I \]
Hence \( i_N \xi = 0 \) and one may write \( \xi|_{(\sigma^1, \bar{\sigma})} = \xi_I(\sigma^1, \bar{\sigma}) d\sigma^I \). Now
\[
\xi_I(\sigma^1, \bar{\sigma}) = \int_{\tau = \tau_0(\bar{\sigma}) - \sigma^1}^{0} \beta_I(\sigma^1 + \tau, \bar{\sigma}) d\tau + \zeta_I(\tau_0(\bar{\sigma}), \bar{\sigma}) \\
= \int_{\tau = \tau_0(\bar{\sigma})}^{\sigma^1} \beta_I(\tau', \bar{\sigma}) d\tau' + \zeta_I(\tau_0(\bar{\sigma}), \bar{\sigma})
\]
where \( \tau' = \tau + \sigma^1 \) and
\[
i_N d\xi|_{(\sigma^1, \bar{\sigma})} = i_{\partial/\partial \sigma^1} d(\xi_I(\sigma^1, \bar{\sigma}) d\sigma^I) = i_{\partial/\partial \sigma^1} \left( d\xi_I(\sigma^1, \bar{\sigma}) \wedge d\sigma^I \right) = \frac{\partial \xi_I(\sigma^1, \bar{\sigma})}{\partial \sigma^1} d\sigma^I
\]
\[
= \frac{\partial}{\partial \sigma^1} \left( \int_{\tau = \tau_0(\bar{\sigma})}^{\sigma^1} \beta_I(\tau', \bar{\sigma}) d\tau' + \zeta_I(\tau_0(\bar{\sigma}), \bar{\sigma}) \right) d\sigma^I = \beta_I(\sigma^1, \bar{\sigma}) d\sigma^I = \beta|_{(\sigma^1, \bar{\sigma})}
\]
Since \( \sigma^1 = 0 \) on \( \Sigma_N \)
\[
\xi|_{(0, \bar{\sigma})} = \xi_I(\tau_0(0, \bar{\sigma}), \bar{\sigma}) d\sigma^I = \xi_I(\tau_0(\bar{\sigma}), \bar{\sigma}) d\sigma^I = \zeta_I(\tau_0(\bar{\sigma}), \bar{\sigma}) = \zeta|_{(0, \bar{\sigma})}
\]
i.e. \( \xi|_{\Sigma_N} = \zeta \).

Lemma 6. Proof that (66,67) implies (61) and that (66,69) implies (61).

**Proof.** First (67) is equivalent to (69) since given \( \gamma \in \Gamma \Lambda^2 M^+_Y \) one has \( \overline{i_{(y,u) \gamma}} = u^a \gamma_{ab} g^{bc} \frac{\partial}{\partial y^c} \) and hence \( \tilde{W}^{\gamma} = \frac{\partial}{\partial \sigma^1} \left( \int_{\tau = \tau_0(\bar{\sigma})}^{\sigma^1} \beta_I(\tau', \bar{\sigma}) d\tau' + \zeta_I(\tau_0(\bar{\sigma}), \bar{\sigma}) \right) d\sigma^I = \beta|_{(\sigma^1, \bar{\sigma})} \). From (67) it follows that
\[
\chi^{[\gamma]} \wedge p_Y^* \gamma = \frac{1}{q_{\gamma}} \frac{m_{[\gamma]}}{b_{[\gamma]}} \chi dy^{cd} \wedge \bar{i}_{abc} \psi^{[\gamma]}\left( d\tau \wedge \omega^{[\gamma]}(g_{\nu a} u_i^{b a}_{\nu}(\theta_{\gamma}^{[\gamma]})) \right) \wedge p_Y^* \gamma
\]
\[
= \frac{1}{q_{\gamma}} \frac{m_{[\gamma]}}{b_{[\gamma]}} \chi \psi^{[\gamma]} \left( d\tau \wedge \omega^{[\gamma]}(g_{\nu a} u_i^{b a}_{\nu}(\theta_{\gamma}^{[\gamma]})) \right) \wedge p_Y^* \gamma
\]
\[
= -\frac{1}{q_{\gamma}} \frac{m_{[\gamma]}}{b_{[\gamma]}} \chi \psi^{[\gamma]} \left( d\tau \wedge \omega^{[\gamma]}(g_{\nu a} u_i^{b a}_{\nu}(\theta_{\gamma}^{[\gamma]})) \right) \wedge p_Y^* \gamma
\]
\[
= -\frac{1}{q_{\gamma}} \frac{m_{[\gamma]}}{b_{[\gamma]}} \chi \psi^{[\gamma]} \left( d\tau \wedge \omega^{[\gamma]}(g_{\nu a} u_i^{b a}_{\nu}(\theta_{\gamma}^{[\gamma]})) \right) \wedge p_Y^* \gamma
\]
i.e. (69). That (69) implies (67) follows since the above argument is true for all \( \gamma \).

To prove (61) note that the domains \( \mathcal{N}_X^{[\gamma]} \) and \( \mathcal{N}_Y^{[\gamma]} \) are related via the diffeomorphism
\[
\mathbf{T}^{[\gamma]} : \mathcal{N}_X^{[\gamma]} \to \mathcal{N}_Y^{[\gamma]}, \quad \mathbf{T}^{[\gamma]}(\tau, y, u) = (- \tau, \dot{C}^{[\gamma]}(y,u)(\tau))
\]
\[\text{A6}\]
Thus \( \mathbf{T}^{[\gamma]}(d\tau) = -d\tau \) and setting \( (x, v) = \dot{C}^{[\gamma]}(y,u)(\tau) \) with \( \tau > 0 \) yields
\[
\phi^{[\gamma]}(\mathbf{T}^{[\gamma]}(\tau, y, u)) = \phi^{[\gamma]}(- \tau, \dot{C}^{[\gamma]}(y,u)(\tau)) = \phi^{[\gamma]}(- \tau, x, v) = (y, u) = \omega^{[\gamma]}(\tau, y, u)
\]
so that \( \varpi_Y^{[\alpha]} = \phi^{[\beta]} \circ \Upsilon^{[\alpha]} \) and thus \( \varpi_Y^{[\alpha]} = \Upsilon^{[\alpha]} \circ \phi^{[\beta]} \). Now

\[
\Upsilon^{[\alpha]} \left( d\tau \wedge \phi^{[\beta]} \left( i_{W^{[\alpha]}(F_1)} \theta_0^{[\alpha]} \right) \right) = \Upsilon^{[\alpha]} \left( d\tau \wedge \Upsilon^{[\beta]} \circ \phi^{[\beta]} \left( i_{W^{[\alpha]}(F_1)} \theta_0^{[\alpha]} \right) \right) = -d\tau \wedge \varpi_Y^{[\alpha]} \left( i_{W^{[\alpha]}(F_1)} \theta_0^{[\alpha]} \right)
\]

hence

\[
\chi^{[\alpha]} \wedge p_X^* F_1 = q^{[\alpha]} \ast_X S \Psi^{[\beta]} \circ \Upsilon^{[\alpha]} \left( d\tau \wedge \phi^{[\beta]} \left( i_{W^{[\alpha]}(F_1)} \theta_0^{[\alpha]} \right) \right) \]

From (63)

\[
p_X \left( \Phi^{[\beta]}(\tau, y, u) \right) = p_X \left( C^{[\beta]}(\tau, y, u) \right) = C^{[\alpha]}(\tau)
\]

and from (A6)

\[
\pi_X \left( \varpi_X^{[\alpha]} \left( \Upsilon^{[\alpha]}(\tau, y, u) \right) \right) = \pi_X \left( \varpi_X^{[\alpha]} \left( -\tau, C^{[\beta]}(\tau, y, u) \right) \right) = \pi_X \left( C^{[\beta]}(\tau, y, u) \right) = C^{[\alpha]}(\tau)
\]

Hence \( p_X \circ \Phi^{[\beta]} = \pi_X \circ \varpi_X^{[\alpha]} \circ \Upsilon^{[\alpha]} \) and so

\[
\Phi^{[\beta]} \circ p_X^* = \Upsilon^{[\alpha]} \circ \varpi_X^{[\alpha]} \circ \pi_X
\]

For convenience set \( \alpha^{[\beta]} = d\tau \wedge \phi^{[\beta]} \left( i_{W^{[\alpha]}(F_1)} \theta_0^{[\alpha]} \right) \in \Gamma^{\alpha} \mathcal{N}_X^{[\alpha]} \). For fixed \( x \) assume that \( F_1 \) has support in \( \mathcal{D}_x \). Then one can choose \( \beta \in \Gamma^{\alpha} \mathcal{M}_X \) so that \( p_X^* \beta \land p_X^* F_1 \) has support inside \( \mathcal{D} \). Thus from (A7)

\[
\text{supp} \left( p_X^* (\ast \beta) \land \Psi^{[\beta]} \circ \Upsilon^{[\alpha]} \circ \alpha^{[\beta]} \right) = \text{supp} \left( p_X^* \beta \land \chi^{[\alpha]} \wedge p_X^* F_1 \right) \subset \mathcal{D}
\]
Now

\[
\int_{M_X} \beta \wedge \int_{p_X} \chi^{[\alpha]} \wedge p_Y^* F_1 = \int_{M_X} \beta \wedge \int_{p_X} \chi^{[\alpha]} \wedge q^{[\alpha]} \ast_X S \Psi^{[\alpha]} \ast \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (A7)}
\]

\[
= q^{[\alpha]} \int_{M_X} \beta \wedge \int_{p_X} S \Psi^{[\alpha]} \ast \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (A2)}
\]

\[
= q^{[\alpha]} \int_{M_X} \beta \wedge \int_{p_X} \Psi^{[\alpha]} \ast \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (A9)}
\]

\[
= -q^{[\alpha]} \int_{M_X} (\ast \beta) \wedge \int_{p_X} \Psi^{[\alpha]} \ast \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (3)}
\]

\[
= -q^{[\alpha]} \int_{M_X \times M_Y} p_X^*(\ast \beta) \wedge \Psi^{[\alpha]} \ast \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (A12)}
\]

\[
= -q^{[\alpha]} \int_{D} \Psi^{[\alpha]} \left( \Phi^{[\alpha]} \ast p_X^*(\ast \beta) \wedge \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \right) \quad \text{from (64)}
\]

\[
= -q^{[\alpha]} \int_{D'} \Phi^{[\alpha]} \ast p_X^*(\ast \beta) \wedge \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (A10)}
\]

\[
= -q^{[\alpha]} \int_{\mathcal{N}^{[\alpha]}_Y} \Phi^{[\alpha]} \ast p_X^*(\ast \beta) \wedge \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{since } D' \subset \mathcal{N}^{[\alpha]}_Y
\]

\[
= -q^{[\alpha]} \int_{\mathcal{N}^{[\alpha]}_Y} \Gamma^{[\alpha]} \wedge \pi_X^*[\ast \chi^*[\ast \beta)] \wedge \Gamma^{[\alpha]} \wedge \alpha^{[\alpha]} \quad \text{from (A8)}
\]

\[
= -q^{[\alpha]} \int_{\mathcal{N}^{[\alpha]}_Y} \pi_X^*[\ast \chi^*[\ast \beta)] \wedge \alpha^{[\alpha]} \quad \text{from (A11)}
\]

\[
= -q^{[\alpha]} \int_{E_X} \pi_X^*[\ast \chi^*[\ast \beta)] \wedge \alpha^{[\alpha]} \quad \text{from (3)}
\]

\[
= -q^{[\alpha]} \int_{M_X} (\ast \beta) \wedge \int_{\pi_X} \int_{\pi_X^*[\ast \chi^*[\ast \alpha]} \alpha^{[\alpha]} \quad \text{from (3)}
\]

\[
= q^{[\alpha]} \int_{M_X} \beta \wedge \int_{p_X} \chi \wedge p_Y^* F_1 = \sum_{[\alpha]} q^{[\alpha]} \int_{M_X} \beta \wedge \int_{p_X} \chi \wedge p_Y^* F_1 \alpha^{[\alpha]}
\]

Summing over [\alpha] gives

\[
\int_{M_X} \beta \wedge \int_{p_X} \chi \wedge p_Y^* F_1 = \sum_{[\alpha]} q^{[\alpha]} \int_{M_X} \beta \wedge \int_{p_X} \chi \wedge p_Y^* F_1 \alpha^{[\alpha]}
\]

Since this is true for all \beta with support in a neighbourhood of x then (61) holds at x.

\[\square\]

**Lemma 7.** The derivation of (72) from (67).

**Proof.** The derivation of (72) from (67) follows by first writing the Liouville vector field (36) as

\[W_0^{[\alpha]} = u^a \frac{\partial}{\partial y^a} + H^{[\nu]} \frac{\partial}{\partial u^{[\nu]}} \quad \text{where} \quad H^{[\nu]} = -\Gamma^{[\nu]}_{\epsilon f} u^\epsilon u^f + \frac{q^{[\alpha]} m^{[\alpha]}}{F_{0[\epsilon f]} g^{[\nu]}} u^f\]

36
Then setting \( f^{(\alpha)}(y, u) = f_0^{(\alpha)}(y, u) + f_1^{(\alpha)}(y, u) \) it follows from (31) that

\[
\theta_0^{(\alpha)} = i_{W_0^{(\alpha)}}(f_0^{(\alpha)} \Omega) = f_0^{(\alpha)} i_{W_0^{(\alpha)}}\left( \frac{|\det g|}{u_0} g^{0123} \wedge du^{0123} \right) = f_0^{(\alpha)} \frac{|\det g|}{u_0} \left( u^c Y_c \wedge du^{0123} + \frac{1}{2} H^\mu \epsilon_{\mu\sigma\rho} Y \wedge du^{\sigma} \right)
\]

where \( Y_a = \frac{\partial}{\partial y^a} g^{0123} \) and \( Y = dy^{0123} \). Consequently

\[
g^{\mu a} u^{b i^a(\alpha)} \theta_0^{(\alpha)} = f_0^{(\alpha)} \frac{|\det g|}{u_0} g^{\mu a} u^{b} \left( -\frac{1}{2} u^c \epsilon_{\mu\sigma\rho} Y_c \wedge du^{\sigma} - H^\nu \epsilon_{\nu\sigma\rho} Y \wedge du^{\sigma} \right)
\]

and

\[
-d\tau \wedge g^{\mu a} u^{b i^a(\alpha)} \theta_0^{(\alpha)} = f_0^{(\alpha)} \frac{|\det g|}{u_0} g^{\mu a} u^{b} \epsilon_{\rho \sigma \nu} \left( \frac{u^c}{2} d\tau \wedge Y_c \wedge du^{\sigma} + H^\nu d\tau \wedge Y \wedge du^{\sigma} \right)
\]

Under the maps \( \varpi_Y^{(\alpha)} \) and \( \hat{\psi}^{(\alpha)} \) one has

\[
\varpi_Y^{(\alpha)}(dy^a) = dy^a, \quad \varpi_Y^{(\alpha)*}(du^\mu) = du^\mu
\]

and

\[
\hat{\psi}^{(\alpha)}(dy^a) = dy^a, \quad \hat{\psi}^{(\alpha)*}(du^\mu) = \frac{\partial u^\mu}{\partial x^a} dx^a + \frac{\partial u^\mu}{\partial y^a} dy^a, \quad \hat{\psi}^{(\alpha)}(d\tau) = \frac{\partial \tau}{\partial x^a} dx^a + \frac{\partial \tau}{\partial y^a} dy^a
\]

So using the projector \( S \) given in (70)

\[
-S \hat{\psi}^{(\alpha)}(d\tau \wedge g^{\mu a} u^{b i^a(\alpha)} \theta_0^{(\alpha)}) = f_0^{(\alpha)} \frac{|\det g|}{u_0} g^{\mu a} u^{b} \epsilon_{\rho \sigma \nu} \left( \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} + \frac{u^c}{2} \frac{\partial \tau}{\partial y^a} \frac{\partial u^\sigma}{\partial y^e} \right) + \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial y^e} + H^\nu \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} Y \wedge dx^{de}
\]

Hence from (67)

\[
\chi^{(\alpha)} = - \frac{q^{[\alpha]2}}{m^{[\alpha]}} \chi \left( \varpi_Y^{(\alpha)}(g^{\mu a} u^{b i^a(\alpha)} \theta_0^{(\alpha)}) \right) = \frac{q^{[\alpha]2}}{m^{[\alpha]}} \chi \left( \frac{|\det g|}{u_0} g^{\mu a} u^{b} \epsilon_{\rho \sigma \nu} \left( \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} + \frac{u^c}{2} \frac{\partial \tau}{\partial y^a} \frac{\partial u^\sigma}{\partial y^e} \right) + \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial y^e} + H^\nu \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} Y \wedge dx^{de} \right) = - \chi \left( f_0^{(\alpha)} \frac{|\det g|}{u_0} g^{\mu a} u^{b} \epsilon_{\rho \sigma \nu} \left( \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} + \frac{u^c}{2} \frac{\partial \tau}{\partial y^a} \frac{\partial u^\sigma}{\partial y^e} \right) + \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial y^e} + H^\nu \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} \right) dx^{de} \right) dx^f
\]

\[
= \frac{q^{[\alpha]2}}{m^{[\alpha]}} \left( \frac{f_0^{(\alpha)}}{2u_0} \right)^3 g^{\mu a} u^{b} \epsilon_{\rho \sigma \nu} \left( \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} + \frac{u^c}{2} \frac{\partial \tau}{\partial y^a} \frac{\partial u^\sigma}{\partial y^e} \right) dx^{de} \wedge dy^f
\]

\[
= \left( \frac{f_0^{(\alpha)}}{2u_0} \right)^3 g^{\mu a} u^{b} \epsilon_{\rho \sigma \nu} \left( \frac{u^c}{2} \frac{\partial \tau}{\partial x^a} \frac{\partial u^\sigma}{\partial x^e} + \frac{u^c}{2} \frac{\partial \tau}{\partial y^a} \frac{\partial u^\sigma}{\partial y^e} \right) dx^{de} \wedge dy^f
\]
