Abstract. Claudins are a family of tight junction proteins, and serve important roles in epithelial barrier, selective ion transports and cancer metastasis. Although the exact role of claudin-7 in human lung cancer has not been completely elucidated, recent clinical studies have demonstrated that claudin-7 is associated with the survival of patients with lung cancer. Our previous studies have demonstrated that claudin-7 forms a protein complex with integrin β1 in human lung cancer cells. The knockdown (KD) of claudin-7 by short hairpin RNA (shRNA) reduced integrin β1 expression and increased the cell proliferative rate, whereas claudin-7 re-expression in the KD cells decreased the cell proliferation. It is unknown as to whether claudin-7 and integrin β1 regulate cell proliferation and invasion synergistically or independently. In the present study, it was observed that ectopic expression of integrin β1 in claudin-7 KD lung cancer cells did not reduce the cell proliferation. However, integrin β1-transfected cells migrated more effectively in wound healing and cell invasion assays and were more adhesive in a cell attachment assay when compared with those of claudin-7 KD cells. This indicates that claudin-7 controls cell proliferation, while cell attachment and motility were regulated partially through integrin β1. Additionally, claudin-7 overexpression in claudin-7 KD cells resulted in an improved ability to attach to the surface of cell culture plates and a higher expression of focal adhesion proteins when compared with claudin-7 non-KD control cells, which supports the role of claudin-7 in cell adhesion and motility. Taken together, these data suggest that claudin-7 regulates cell motility through integrin β1, providing additional insight into the roles of claudins in carcinogenesis and cancer cell metastasis.

Introduction

Human lung cancer is the second leading cause of mortality in the United States (1). The lung expresses various tight junction (TJ) proteins depending on their compartments, including claudin-1, -2, -3, -5, -7, -8, and -18. TJ proteins are one of the cellular junctional proteins located at the apical side of epithelial cells, and they regulate paracellular permeability between neighboring epithelial cells (3). One of the TJ proteins is the claudin family that consists of four transmembrane spanning proteins (3). Although the function of claudins as epithelial barriers for the maintenance of cell polarity and selective ion transport has been well established (4), their role in diseases, including cancer, is unclear. However, a possible link between TJs and metastasis has been recently demonstrated using human colon cancer cell lines in vitro (5,6). The varying levels of claudin expression may be correlated to cancer progression (7). Additionally, claudin-5 has been shown to form a protein complex with ROCK and N-WASP and promote actin cytoskeletal movement in breast cancer cells (8), suggesting that TJ proteins are crucial for cancer cell motility.

A recent clinical research study has shown that claudin-7 expression is associated with the survival of lung cancer patients after surgery (9), suggesting the role of claudin-7 in cancer progression. Results from our previous study demonstrated that claudin-7 knockdown (KD) in HCC827 human lung cancer cell lines increased cell proliferation and reduced integrin β1 expression and cell adhesion (10). Interestingly, claudin-7 was able to form a protein complex with integrin β1 and was partially co-localized at the basolateral membrane of HCC827 control cells (10). This suggests a possibility that claudin-7 and integrin β1 co-regulate cellular events, including cell proliferation and adhesion; however, this has not been fully explored. Several studies have shown the basal localization of claudin-7 in the epithelial cells of several organs, including mammary gland, kidney, and uterine, suggesting the roles of claudin-7 in cell-matrix adhesion (11-13) and vesicle trafficking (13). In this study, we investigated whether integrin β1 and claudin-7 independently or synergistically functioned on cell proliferation, adhesion, migration, invasion, and attachment. Our results demonstrate that ectopic expression of integrin β1 partially recovers the cell adhesion, migration, invasion and attachment, but not cell proliferation, of claudin-7 KD cells.
**Materials and methods**

**Antibodies.** Rabbit polyclonal anti-phospho-Y397-FAK, anti-FAK, anti-phospho-Y118-Paxillin, and anti-GAPDH were purchased from Cell Signaling Technology (Danvers, MA, USA). Anti-integrin β1 antibodies were obtained from BD Biosciences and Santa Cruz Biotechnology, Inc. (Dallas, TX, USA). Anti-Paxillin antibody was from BD Transduction Laboratories (San Jose, CA, USA). The secondary anti-mouse and anti-rabbit antibodies tagged with HRP were purchased from Promega (Madison, WI, USA). Rabbit polyclonal anti-claudin-7 antibody was obtained from Immuno-Biological Laboratories (Gunma, Japan), and mouse monoclonal anti-Myc antibody was obtained from Thermo Fisher Scientific, Inc. (Waltham, MA, USA).

**Cell lines and reagents.** The HCC827 human non-small cell lung cancer (NSCLC) cell line was obtained from American Type Culture Collection (ATCC) (Manassas, VA, USA) and cultured in RPMI-1640 medium (Thermo Fisher Scientific, Inc.) supplemented with heat-inactivated 10% fetal bovine serum (HyClone; GE Healthcare, Chicago, IL, USA), 1% 10,000 U/ml penicillin, and 10,000 µg/ml streptomycin in a 37°C, 5% CO₂ humidified incubator. HCC827 control or Claudin-7 KD cell lines were previously established (10).

**Transfection and establishment of stably transfected cell lines.** In order to establish the stable transfection of integrin β1 in HCC827 KD cells (KD+b1 cells), the integrin β1 cDNA vector (Transomics, Huntsville, AL, USA) was digested at EcoRI and NotI restriction enzyme sites. The size of integrin β1 cDNA insert was confirmed from DNA electrophoresis. The insert was gel-purified using a Gel Extraction kit (Qiagen, Inc., Valencia, CA, USA), and then sub-cloned to a pcDNA3.1 vector at EcoRI and NotI restriction sites. After the pcDNA3.1-integrin β1 cDNA vector was transfected to HCC827 KD cells using Amaxa Nucleofector™ Kit V reagent (Lonza, South Plainfield, NJ, USA) by electroporation, the stably transfected cells were selected at 600 µg/ml Geneticin (G418) for 4 weeks. The stable transfectants were maintained in the culture medium containing 300 µg/ml G418. For the transient transfection, pcDNA3.1-claudin-7-myc (mouse claudin-7 cDNA) vector was transfected to HCC827 KD cell lines and the transfectants were incubated and recovered overnight under an antibiotics-free medium. The transfectants were given fresh media the next day and used for the experiment within 72 h.

**SDS-PAGE and western blotting.** Whole cells were lysed in RIPA buffer (1% Triton-100, 0.5% deoxycholate, 0.2% sodium dodecyl sulfate, 150 mM sodium chloride, 2 mM ethylene diamine tetra-aceitic acid, 10 mM sodium pyrophosphate, 20 mM sodium fluoride) supplemented with a complete protease inhibitor cocktail tablet (Roche Diagnostics, Indianapolis, IN, USA). After cell debris from the protein lysate was removed by centrifugation at 4°C, protein concentration was measured using a Pierce™ BCA Protein Assay Kit (Thermo Fisher Scientific, Inc.). Proteins (20 µg per lane) were separated by SDS-PAGE gel, transferred to the nitrocellulose membrane (GE Healthcare) by electrophoresis, then blocked in 5% non-fat dried milk in PBS plus 0.1% Tween 20, and incubated with appropriate primary antibodies followed by peroxidase-conjugated secondary antibodies. Protein bands were visualized using ECL detection reagents (GE Healthcare) and photographed using an X-ray film developer.

**Cell proliferation and cell attachment assays.** A total of 2x10⁴ HCC827 control, claudin-7 KD, and KD+b1 cells were seeded in a 6-well plate and the total cell numbers were counted after 2, 4 and 6 days by Trypan Blue exclusion method using a Countess™ automated cell counter (Invitrogen; Thermo Fisher Scientific, Inc.).

For the cell attachment assay, 2x10³ HCC827 control, claudin-7 KD and KD+b1 cells were seeded in a 12-well plate. After 4 h incubation at 37°C in a 5% CO₂ humidified chamber, the culture medium was removed, and each well was washed briefly with PBS buffer to remove unattached cells. Then, the remaining attached cells were trypsinized and mixed with 6 µm AlignFlow Plus beads (Molecular Probes; Thermo Fisher Scientific, Inc.) at a concentration of 1x10⁵ beads/ml. Total cell numbers were calculated from the relative ratio of beads to cells using a FACScan flow cytometer.

**Wound healing assay.** The control, claudin-7 KD, and KD+b1 cells were plated in a 6-well plate until confluent. The cells were then cultured in the serum-free medium for 22 h. After creating a scratch, the serum-containing medium was given, and the gap distance was photographed using an inverted Zeiss light microscope (Carl Zeiss Inc., Thornwood, NY, USA) and analyzed by MetaMorph software (Molecular Devices, LLC, Sunnyvale, CA, USA) at time points of 0, 3, 6, 12 and 24 h. The closed gap distance per each time point was normalized to its respective initial gap distance at time point 0 per cell line.

**In vitro cell invasion assay.** A total of 2x10⁵ HCC827 control, KD, and KD+b1 cells were suspended and seeded in 500 µl of serum-free RPMI-1640 on the membrane of the inner chamber in a 6-well BD Matrigel plate. The outer chamber was also filled with the serum-free medium. After 24 h serum starvation, the serum-containing culture medium was added in the outer chamber. After 53 h incubation at 37°C in a 5% CO₂ humidified incubator, the membranes from the inner chamber were scrubbed using a medium-wetted cotton swab. Counter cell staining was performed using modified protocols from the Hema-3 Stain kit (Thermo Fisher Scientific, Inc.). In brief, the membranes were first fixed with fixative (Hema-3 Fixative) for 4 min, then stained in red color solution I (Hema-3 Solution I) for 10 min (cytosol staining), and then stained in blue color solution II (Hema-3 Solution II) for 10 min (nucleus staining). After two brief washes with de-ionized water, the membranes were quickly air-dried and mounted with glycerol on glass slides. Five areas per membrane sample were randomly selected under an inverted light microscope at 200 x magnification using a Zeiss Axiolab S100 microscope (Carl Zeiss Inc.) and photographed using Axiovision 4.6 imaging software (Carl Zeiss Inc.).

**Statistical analysis.** All experiments were performed at least three times and data were presented as means ± standard error of means. One- or two-way ANOVA followed by a post-hoc
Tukey test was performed in samples from three cell lines using IBM SPSS software (Version 23.0; IBM Corp., Armonk, NY, USA). P<0.05 was considered to indicate a statistically significant difference.

Results

Ectopic expression of integrin β1 did not alter the cell proliferative rate of claudin-7 KD cells. Our previous study showed that HCC827 claudin-7 KD lung cancer cells increased the cell proliferative rate, decreased the expression of a variety of ECM components (including collagen IV and cell adhesion proteins such as integrin β1), and displayed reduced cell adhesion compared to HCC827 cells with no claudin-7 KD (claudin-7 control cells) (10). Although the reduced cell adhesion and ECM components appeared to accelerate the proliferative rate of the KD cells, supplementing the KD cells with collagen IV improved cell attachment but did not change the cell hyper-proliferative phenotype (10). This suggests that cell adhesion proteins such as integrin β1 may be more important in regulating cell adhesion and migration. To investigate whether re-expression of integrin β1 could affect the cell proliferative rate of claudin-7 KD cells in a manner comparable to that of control cells, we transfected integrin β1 cDNA into the claudin-7 KD cells (KD+b1) as shown in Fig. 1A. The protein expression level of integrin β1 in all three cell lines were assayed by Western blotting and quantified by densitometry (Fig. 1A). Our results showed that the cell number of KD cells were substantially higher than that of the control cell on day 6 (P<0.01) (Fig. 1B), which is consistent with our previous report (10). However, the cell numbers of the KD and KD+b1 cells were not different on day 4 (8.1x10^4±1.7x10^3 vs. 7.4x10^4±1.0x10^4) or day 6 (1.5x10^5±1.2x10^4 vs. 1.5x10^5±1.8x10^4). This result showed that integrin β1 expression did not rescue the claudin-7 KD cell hyper-proliferative phenotype, suggesting that integrin β1 may not be directly involved in regulating the cell proliferation of claudin-7 KD cells.

Ectopic expression of integrin β1 partially recovered the cell adhesion of claudin-7 KD cells. Although claudin-7 KD cells increased the cell proliferative rate, they exhibited a reduction in cell adhesion and integrin β1 expression (10). In addition, integrin β1 and claudin-7 formed a protein complex, and they were co-localized at the basolateral membrane of HCC827 control cells (10). This suggests the possibility of claudin-7 regulation of cell adhesion through integrin β1. Therefore, we ectopically expressed integrin β1 in the claudin-7 KD cells to examine whether claudin-7 regulated-cell adhesion occurs through integrin β1. Similar to the control cells, KD+b1 cells also formed a monolayer on glass coverslips, though a spheroidal clump remained, indicating the incomplete cell

Figure 1. Exogenous integrin β1 expression did not reduce hyper-proliferation of claudin-7 KD cells. (A) A representative western blot result shows the integrin β1 expression level in control and claudin-7 KD cells (KD), as well as claudin-7 KD cells transfected with integrin β1 cDNA vector (KD+b1) (Left panel). GAPDH served as a loading control. The right panel shows the densitometry measurements for three independent experiments. There are no statistical significant differences among three groups. (B) A total of 2x10^4 control, KD and KD+b1 cells were seeded in 12-well plates and the cell numbers were counted for each sample 2, 4, and 6 days following the initial cell culture date. KD+b1 cells did not exhibit any significant changes in cell proliferation rate when compared with Claudin-7 KD cells during the entire cell growth period. The KD and KD+b1 cells exhibited significantly higher proliferating cell numbers when compared to the control cells on day 6 (*P<0.05; **P<0.01). At least three experiments were performed for statistical analysis. KD, knockdown. *P<0.05; **P<0.01.

Figure 2. Exogenous integrin β1 expression improved cell-matrix adhesion of claudin-7 KD cells. (A) Cells were cultured on glass coverslips. The control cells developed a complete monolayer while all claudin-7 KD cells showed spheroid colonies. KD+b1 cells formed a partial monolayer with a spheroid cell clump indicating incomplete cell spreading. The phase images were photographed at x100 magnification. (B) A scratch was created using a pipet tip on each confluent control, KD and KD+b1 cell monolayer. Compared to the control cells, the KD+b1 cells were attached to the plate fairly well, whereas the claudin-7 KD cells were stripped off along the scratch (shown as black arrows). (C) A higher magnification of KD and KD+b1 cells shown in B to enlarge the stripped off regions at the scratch site. Scale bar: 10 µm for A and B, 25 µm for C. KD, knockdown.
spreading, whereas claudin-7 KD cells displayed spheroidal colonies only, as previously reported (Fig. 2A) (10). Likewise, KD+b1 cell layers around the scratch site were less stripped off than the claudin-7 KD cell layers (Fig. 2B, arrows). Fig. 2C show more clearly the stripped off regions at the scratch site of claudin-7 KD and claudin-7 KD+b1 cells. These results demonstrate that ectopic expression of integrin β1 partially improved the reduced ability of cell attachment to the dish in the claudin-7 KD cells.

**Ectopic expression of integrin β1 enhanced cell migration and invasion ability of claudin-7 KD cells.** We showed that ectopic expression of integrin β1 partially recovered cell adhesion of claudin-7 KD cells, but the effects of claudin-7 via integrin β1 on cell motility have not been studied before. Thus, we next examined whether transfection of integrin β1 affected the cell migration and invasion of claudin-7 KD cells using wound healing and cell Matrigel invasion assays, respectively. Wound healing assay showed that KD+b1 cells migrated faster than claudin-7 KD cells (P<0.05), but slower than control cells at all-time points (Fig. 3A and B), indicating that integrin β1 increased the KD cell migration caused by claudin-7 knockdown. Additionally, KD+b1 cells invaded more efficiently than claudin-7 KD cells (P<0.01), but less efficiently than the control cells (P<0.05) (Fig. 4A and B), indicating that integrin β1 transfection also promoted the cell invasiveness of the KD cells.

**Ectopic expression of integrin β1 partially restored defective cell attachment of claudin-7 KD cells.** Integrin β1 transfection significantly improved the cell adhesion of claudin-7 KD cells, indicating that claudin-7 may result in an increase in cell-matrix attachment via integrin β1 at cell-matrix interactions. Thus, we first investigated whether transfection of integrin β1 sufficiently improved the cell-matrix attachment of claudin-7 KD cells comparable to the control cells. The number of KD+b1 cells that remained attached was significantly higher than that of claudin-7 KD cells (P<0.05), but significantly lower than that of control cells (P<0.01) in the cell attachment assay (Fig. 5A). This indicates that integrin β1 transfection partially restores the defect in the cell attachment of claudin-7 KD cell.

In order to fully restore the defective KD cell attachment, we transiently transfected claudin-7 cDNA containing Myc-tag into the KD cells to generate KD+cldn7 cells. The cell attachment results showed that the number of KD+cldn7 cells that remained attached was significantly higher than that of claudin-7 KD cells (P<0.01), indicating that overexpression of claudin-7 strengthened the cell-matrix attachment of the KD cells far better. Western blot analysis confirmed the ectopic expression of integrin β1 or claudin-7 in KD cells (Fig. 5C). Although integrin β1 expression moderately increased the level of phospho-FAK in KD cells compared to that of the control cells, claudin-7

---

**Figures:**
- Figure 3. Exogenous integrin β1 expression increased the cell migration of claudin-7 KD cells. (A) A panel of representative light phase images of control, KD and KD+b1 cells in wound healing assay plates were photographed at x200 magnification at a specified time point. Scale bar: 10 μm. (B) Relative cell migration rate on each cell line in wound healing assay. The relative cell migration distance was estimated as the ratio of the closed gap distance at a given time point over initially created gap distance at 0 time point. KD+b1 cells migrated more effectively than claudin-7 KD cells (P<0.05). At least three experiments were repeated for statistical analysis. KD, knockdown.

- Figure 4. Exogenous integrin β1 expression increased the cell invasion ability of claudin-7 KD cells. (A) Cell invasion assay. A panel of representative light phase images of control, KD and KD+b1 cells were photographed at x200 magnification. At least three experiments were performed for statistical analysis shown in B. Scale bar: 20 μm. (B) The numbers of nucleus stained by blue dye (Hema-3 Solution II) were counted and averaged from 5 randomly chosen areas per cell line from each of three independent experiments. Red-dye (Hema-3 Solution I) staining reflected cytosols. *P<0.05; **P<0.01. KD, knockdown.
overexpression greatly elevated the expression levels of phospho-FAK, phospho-Paxillin as well as integrin β1 in KD+cldn7 cells when compared to control cells (Fig. 5C). This result indicates that both integrin β1 and claudin-7 synergistically support cell attachment, although claudin-7 appears to have a greater effect than integrin β1.

Taken together, these results suggest that ectopic expression of integrin β1 in claudin-7 KD cells partially recovered the control cell adhesion, migration and invasion, but not cell proliferation.

Discussion

In this study, we noticed that ectopic expression of integrin β1 in claudin-7 KD cells did not lead to claudin-7 expression, but claudin-7 overexpression in the KD cells sufficiently revived integrin β1 expression. Our previous study also demonstrated that claudin-7 and integrin β1 formed a protein complex co-localized at the basolateral membrane of HCC827 control cells (10). These results suggest that claudin-7 and integrin β1 may co-operate with each other, although claudin-7 seems to have a greater ability to control cellular phenotypes. For example, ectopic expression of integrin β1 did not change the hyper-proliferative rate of claudin-7 KD cells. However, claudin-7 overexpression in KD cells reduced the cell proliferation rate (10). This indicates that claudin-7 may enable integrin β1 at the basolateral membrane to properly receive signaling from the ECM to control lung cancer cell proliferation. This does not align with some of the reports that integrin β1 signaling regulates cell proliferation and survival (14). For example, deletion of integrin β1 reduces cell proliferation of mammary gland at the cellular level (15,16). At the organ level, integrin β1 knockout mice die before birth (15) probably due to the absence of the integrin β1 signaling. Interestingly, our claudin-7 KD cells suppressed integrin β1 expression but accelerated cell proliferation (10). It is possible that other β integrins could compensate for the lack of integrin β1 signaling to promote cell proliferation. In a breast cancer study, integrin β3 signaling is activated to increase cell proliferation and invasion when integrin β1 is suppressed (17). Future investigation is thus warranted to clarify the compensatory effect of other β integrins in claudin-7 KD cells.

Claudin-7 also synergistically collaborates with integrin β1 to control cell adhesion, migration, invasion and attachment. We demonstrated that KD+b1 cells have improved cell-matrix adhesion when compared to claudin-7 KD cells (Fig. 2), indicating that ectopic expression of integrin β1 supports the role of claudin-7 in cell-matrix adhesion through the basolateral membrane of KD cells. However, KD+b1 cells still showed a reduction in the rate of the cell migration when compared to control cells. Cell migration requires proper cell-matrix adhesion: Focal adhesion, which primarily consists of integrin clustering through cell-matrix interface, maintains an extended actin cytoskeletal protrusion in the direction of cell migration, and it is further stabilized by nascent adhesion along with lamellipodia at the leading cell edge (18,19). The consequentially skewed cell shape accumulates contractile force, which eventually drives cell migration when rear cell adhesion is released (18,19). When claudin-7 is low in quantity, focal adhesion through the basolateral membrane may not be
properly established, inhibiting the subsequent process of cell migration. This suggests that claudin-7 cooperatively regulates cell migration via integrin β1. However, our study also does not rule out the possibility that claudin-7 and integrin β1 act independently.

Similar to the cell migration process, cell-matrix adhesion is also essential in cell invasiveness. Integrins form focal adhesion complexes, which results in the creation of actin cytoskeletal protrusion as an invadopodia precursor (20). In addition, integrin β1 recruits integrin-linked kinase (ILK) that transforms the invadopodia precursor into adhesion ring-containing matured invadopodia (21), which allows the extension of the actin cytoskeletal protrusions and activates ECM degradation activity (20-22). The low amount of claudin-7 may reduce the number of focal adhesion complexes and prevent further processes of cell invasiveness. Although ectopic expression of integrin β1 in KD+b1 cells may increase the numbers of integrin clustering, the low quantity of claudin-7 in the KD+b1 cells may not effectively anchor the integrins β1 through the basolateral membrane and thus make it unable to fully recover the intensity of focal adhesion and degradation enzyme activity as it does in the control cells.

Likewise, cell-matrix adhesion is crucial in cell-matrix attachment. Claudin-7 overexpression in claudin-7 KD cells (KD+cldn7) recovers the cell attachment ability at a far higher level than that of control cells. The increased cell attachment in claudin-7 overexpression is due to the excessive level of focal adhesion proteins confirmed by Western blot results, suggesting that the claudin-7 overexpression at the basolateral membrane of KD+cldn7 cells may bind stronger to the target ECM surface than that of control cells. We were unable to test the metastatic possibility in vivo due to the intrinsically poor metastatic potential of HCC827 cell lines (23). Future study should include more lung cancer cell lines and the in vivo test.

It is interesting to notice that the ectopically expressed claudin-7 leads to a significant increase in cell numbers and strong activation of integrin signaling although its expression level is not as high as the endogenous claudin-7 level in control cells (Fig. 5B and C). One possibility could be due to the claudin-7 phosphorylation level. We know that claudin-7 is a phosphorylated membrane protein (24). It is seen that the ectopically expressed claudin-7 has a higher phosphorylation level compared to the endogenous claudin-7. It is possible that the phosphorylated claudin-7 tends to be membrane bound while non-phosphorylated claudin-7 largely stays in the cytoplasm. It could be the phosphorylated claudin-7 that plays a major role in regulating integrin β1, p-FAK, and p-Paxillin expression. Future work is needed to investigate the differential roles of phosphorylated and non-phosphorylated claudin-7.

In addition, claudin-7 proteins may serve as anchoring domains to recruit other cell adhesion proteins at cell membrane, as previously shown for integrin β1 (10) as well as other cell adhesion proteins, including CD44 and EpCAM (25,26), all of which could contribute to the overall cell-matrix adhesion of lung cancer cells. This may explain, in part, why transfection of integrin β1 in claudin-7 KD cells did not fully recover the cell-matrix adhesion, migration, invasion, and attachment.

The ability of claudin-7 interaction with integrin β1 to establish cell-matrix adhesion appears to be important to understand the molecular mechanism of Human Immunodeficiency Virus (HIV) infection. It has been reported that HIV infected CD4(-) T cell subpopulation when claudin-7 gene was introduced to the HIV particles in vitro (27). However, it remained unclear whether surface ligands in the CD4(-) T cells could interact with claudin-7 on the viral particles. Recently, it has also been reported that peripheral blood lymphocytes from normal patients show the high-level integrin β1 (CD29) surface marker in 66% of CD4(-) T cell subpopulation (28). This suggests that claudin-7 proteins in the HIV-1 viral coat may interact with integrins β1 (CD29) present in the host CD4(-) T cells, which could establish mutual membrane adhesion that allows mediation of the membrane fusion process for entry of the HIV particles to CD4(-) T cells.

In this report, we conclude that claudin-7 functions as a cell adhesion protein that modulates cell-matrix adhesion and regulates cellular process, including lung cancer cell migration, invasion, and attachment.
