Weak atomic convergence of finite voter models toward Fleming-Viot processes

Yu-Ting Chen* and J. Theodore Cox†

August 23, 2016

Abstract

We consider the empirical measures of multi-type voter models with mutation on large finite sets, and prove their weak atomic convergence in the sense of Ethier and Kurtz (1994) toward a Fleming-Viot process. Convergence in the weak atomic topology is strong enough to answer a line of inquiry raised by Aldous (2013) concerning the distributions of the corresponding entropy processes and diversity processes for types.

1 Introduction

Voter models are a generalization of Moran processes [29] from population genetics in the presence of spatial structure, and have been one of the major subjects in interacting particle systems [28] along with their variants in models of cancer, social

dynamics, and probabilistic evolutionary games. See, for example, [3, 8, 9, 10, 14], and the references there for origins of these models. The present paper is a continuation of Chen, Choi and Cox [11] which considers the weak convergence of two-type voter models toward the Wright-Fisher diffusion. Our main goal here is to show that with respect to the weak atomic convergence introduced by Ethier and Kurtz [21], which is finer than the usual weak convergence, infinite-type voter models on large finite sets in the presence of mutation converge to a Fleming-Viot process. Fleming-Viot processes are one of the most well studied classes of measure-valued processes, in part due to its duality with the Kingman coalescent (see [7, 17, 18, 20] and many others).

For the voter models considered throughout this paper we allow multiple types and mutation. The models are defined as follows. With respect to a finite set $E$ with size $\#E = N \geq 2$ and a compact metric type space $S$, a multi-type voter model is defined by a “voting mechanism” according to an irreducible transition kernel $q$ on $E$ with zero trace $q(x, x) \equiv 0$, and incorporates independent mutation according to a finite measure $\mu$ on $S$. The kernel $q$ plays the role of a “voting kernel” in that at rate 1, the type at each $x \in E$ is replaced by the type at $y$ with probability $q(x, y)$. On the other hand, if $\mu$ is nonzero, mutation at each $x \in E$ occurs independently with rate $\mu(1)$, and a new type is chosen according to $\mu(\cdot)/\mu(1)$. The canonical examples for these voter models are defined by voting kernels which are random walk transition probabilities on finite, connected, edge-weighted graphs without self-loops. Here and in what follows, see [5] for terminology in graph theory.

Voter models where voting kernels are random walk transition probabilities on complete graphs reduce to the classical Moran processes. This particular case forms the basis of several important probability models. For example, in the limit of large $N$, frequencies of a fixed type under two-type Moran processes converge to the Wright-Fisher diffusion. Furthermore, in the multi-type case, the empirical measures of the corresponding Moran processes converge to a Fleming-Viot process, which is a measure-valued infinite dimensional generalization of the Wright-Fisher diffusion (cf. [19, Chapter 10], and also Section 3 below). Along these lines, one of the major interests has been in the rich properties of the continuum limits, whereas the mean-field nature of Moran processes allows complete characterizations of those dynamical equations on their own.

The objects of this paper are the empirical measures of voter models on large finite spatial structures. The empirical measure associated with an $(E, q, \mu)$-voter model $(\xi_t)$ is given by the process $(m(\xi_t))$ taking values in the space $\mathcal{P}(S)$ of probability measures on $S$. Here, the probability-measure-valued functional $m$ is defined by

$$m(\xi) = \sum_{x \in E} \pi(x) \delta_{\xi(x)}, \quad \xi \in S^E,$$

where the weight function $\pi$ is the unique stationary distribution associated with the voting kernel $q$. Notice that the mass of $m(\xi)$ at $\sigma$, for $\sigma \in S$, gives the ($\pi$-weighted) density of type $\sigma$ in $\xi$.

The first main result of this paper, Theorem 4.1 below, generalizes the classical result of convergence of multi-type Moran processes to a Fleming-Viot process, and is an infinite-dimensional generalization of [11, Theorem 2.2] where two-type voter models...
models without mutation are investigated. With respect to an appropriate sequence of \((E_n,q^{(n)}_n,\mu_n)\)-voter models \((\xi^{(n)}_t)\) where \(#E_n\) increases to infinity, we establish the weak convergence

\[
\mathbf{m}(\xi^{(n)}_{\gamma_n}) \xrightarrow{n \to \infty} X
\]

as probability-measure-valued processes on the type space \(S\) (with respect to Skorokhod’s \(J_1\)-topology), where \(X\) is a Fleming-Viot process. Here, the time scales \(\gamma_n\) are growing constants given by the expected first meeting times of two independent Markov chains which are driven by the corresponding voting kernels and are started from stationarity, and \(\mathcal{P}(S)\) is equipped with the usual topology of weak convergence. The major conditions for the weak convergence in (1.2) are certain simple, mild mixing conditions on the kernels \(q^{(n)}_n\) expressed in terms of total variation mixing times, or spectral gaps when the kernels are reversible; we also require “weak mutation” so that \(\gamma_n\mu_n\) converges weakly. Either of our two mixing conditions (see Theorem 4.1(iv)) guarantees that two independent \(q^{(n)}-\)Markov chains get appropriately close to stationarity before they meet. They are particular formalizations of the general principle appearing as early as in Keilson [25] and Aldous [1] to obtain the convergence of rescaled hitting times toward exponential variables. See Oliveira [31, 32] for a closely related application of this principle to absorption of voter models without mutation, and Section 5 for an application of Oliveira’s condition to weak atomic convergence of voter models (to be discussed in more detail below).

The proof of (1.2) makes use of the standard duality between voter models and coalescing Markov chains driven by voting kernels (see Section 3). The mixing conditions mentioned above applied to the dual processes lead to the mean-field-like behavior for dynamics of the empirical measures of voter models through duality. In this direction, our application of duality will be kept at a minimum in order to obtain mild conditions on voting kernels for the weak convergence. In more detail, the well-posedness of the martingale problem satisfied by the limiting Fleming-Viot process only requires us to characterize the limits of the first two moments of the empirical measures (against appropriate test functions). On the other hand, the use of the empirical measures in (1.1) means that we consider a direction different from the method of stochastic PDEs for rescaled (two-type) voter models on integer lattices by Mueller and Tribe [30] and Cox, Durrett and Perkins [13]. With respect to a fixed type \(\sigma\), the stochastic PDE method considers certain rescaled limits of the discrete-measure-valued process \(\sum_x 1_{\{\sigma\}}(\xi_t(x))\delta_x\) for a voter model \((\xi_t)\) defined on an integer lattice, where \(x\) ranges over all vertices. In contrast to the context in this paper, the special geometry of integer lattices is required for this method. Nonetheless, as far as a fixed type is concerned, the method can give a much more detailed description of the space-time dynamics of type \(\sigma\) under the voter model, in terms of processes with “cleaner” characterizations.

Up to this point, our program for the weak convergence of empirical measures for multi-type voter models is similar to that in [11] for the weak convergence of density processes for two-type voter models without mutation toward the Wright-Fisher diffusion. However, the multi-type character of the voter models under consideration
and the presence of mutation now bring new technical issues. In particular, the latter changes the delicate duality relation between the voter models and the coalescing Markov chains. The first part of this paper will be devoted to the resolutions of these issues. See Section 2 and Section 3 for details.

The second main result of this paper strengthens the mode of the convergence in (1.2). Our motivation in this direction is a line of inquiry by Aldous [3] on “finite Markov information exchange models”. The context there considers social dynamics for a large population of agents which are located at the vertices of finite, connected, weighted graphs without self-loops. Their “opinions” evolve according to voter model dynamics ($\xi_t$) without mutation. Different opinions are held by the agents in the initial states so that the number of effective types in the system grows with the size of state space.

The inquiry in [3, Section 5.6] concerns the distributions of atoms of empirical measures, which correspond to the proportions of agents with different opinions. As noted in [3] in the study of clusters of opinions, the entropy process $\text{Ent}(m(\xi_t))$ and diversity process $\text{Div}(m(\xi_t))$ associated with a voter model ($\xi_t$) are of particular interest. Here for $\lambda \in \mathcal{P}(S)$, $a(\lambda) = (a_1(\lambda), a_2(\lambda), \ldots)$ denotes the sequence of the atom sizes of $\lambda$ arranged in decreasing order: $a_1(\lambda) \geq a_2(\lambda) \geq \cdots$, and the entropy and diversity of $\lambda$ are defined by

$$\text{Ent}(\lambda) \doteq - \sum_{i=1}^{\infty} a_i(\lambda) \log(a_i(\lambda)), \quad (1.3)$$

$$\text{Div}(\lambda) \doteq \sum_{i=1}^{\infty} a_i(\lambda)^2, \quad (1.4)$$

respectively, with the convention that $a_i(\lambda) = 0$ if the number of atoms of $\lambda$ is less than $i$ and $0 \log 0 = 0$. Notice that entropy emphasizes small atoms, while diversity emphasizes large atoms.

Given (1.1), one may expect that in the limit of large $N$, the distributions of the entropy processes and diversity processes for voter models should be well approximated by the same quantities for the limiting Fleming-Viot process. The main difficulty in obtaining a result along these lines is that, in general, weak convergence of a sequence of probability measures does not imply weak convergence of the sizes and locations of their atoms. In particular, even though the Fleming-Viot process without mutation is almost surely purely atomic at positive times (cf. [19, Theorem 4.5] or [35, Theorem 4.1]), (1.2) suggests but does not imply convergence of the sizes and locations of atoms. On the other hand, Ethier and Kurtz [21] found a way around this difficulty two decades ago by introducing the finer mode of weak atomic convergence. It reinforces the usual weak convergence of measures to the effect that sizes and locations of atoms converge in the natural way (see Section 5 or [21, Section 2] for further discussions, and also [21, Section 4] for its genetic applications to Moran processes). In Theorem 5.1 below we change the weak topology on $\mathcal{P}(S)$ to this finer topology of weak atomic convergence, and establish the weak convergence in (1.2) (again as processes taking values in $\mathcal{P}(S)$) with respect to this topology under an additional mild condition on the mutation measures.
Finally, in the setting of \([3]\) in which mutation is absent, using the weak atomic convergence above and duality again, we obtain convergence of the entropy processes and diversity processes under an additional condition on the systems of coalescing \(q(n)\)-Markov chains (see Theorem 5.2). The condition states that in the limit of large \(E_n\) and with time being rescaled as before, the first time that the effective size of the full system of coalescing Markov chains (starting from all spatial points) reduces to a fixed number converges in distribution. The limit is given by the same limit as in the mean-field case, and can be characterized as a certain convergent series of independent exponential variables with simple parameters which has a natural interpretation that in the limit, the effective size of the coalescing system “comes down from infinity”. This property holds for Moran processes through their duality with the Kingman coalescent \([26]\), and also for certain coalescing random walks on discrete tori by Cox \([12]\). Its general validity under certain mild conditions on the kernels \(q(n)\) was shown only recently in a remarkable result in \([32]\) (see Section 5 for more details). Under this assumption on the dual coalescing Markov chains, the numbers of atoms at fixed positive times under the corresponding time-rescaled voter models are bounded in probability in the limit (Theorem 5.2). The weak convergence of the entropy processes and diversity processes is then a simple consequence of the convergence in (1.2) reinforced to the weak atomic convergence.

In this way, we provide an answer to the inquiry in \([3]\) in terms of the well-established theory of Fleming-Viot processes and via the notion of weak atomic convergence of measure-valued processes in \([21]\).

**Organization of the paper** In Section 2, we study the probability-measure-valued functional \(m\) in (1.1) under generators of finite voter models. We work with two different classes of test functions, one for the weak convergence of the empirical measures for voter models and the other for their weak atomic convergence. In Section 3, we characterize the Fleming-Viot processes, and proceed to some preliminary estimates for the weak convergence of empirical measures associated with voter models to a Fleming-Viot process after an outline of our method. The proof of the weak convergence of empirical measures in (1.2) is then presented in Section 4, and the result can be found in Theorem 4.1. In Section 5, we first discuss briefly the Ethier-Kurtz weak atomic convergence introduced in \([21]\) and then prove Theorem 5.1. We further reinforce Theorem 5.1 in Theorem 5.2, obtaining convergence of atom-size point processes for voter models in the absence of mutation. Characterizations of the limiting processes for the entropy processes and the diversity processes then follow. Finally, we close this paper with Section 6. There, for the convenience of the reader, we give a brief self-contained treatment of duality which allows us to prove the key probability estimate (3.5) in Section 3.
2 Dynamics of empirical measures for voter models

In this section, we study empirical measures under the generator of an \((E, q, \mu)\)-voter model. The pair \((E, q)\) is an irreducible transition kernel with stationary distribution \(\pi\) and satisfies the zero trace condition \(q(x, x) \equiv 0\). The mutation measure \(\mu\) is a finite measure on \(S\). These assumptions on voting kernels and mutation measures will be in force throughout the rest of this paper.

By our description of the \((E, q, \mu)\)-voter model in Section 1, the generator of the voter model is given by

\[
L^\mu_{\mathcal{VM}} F(\xi) = \sum_{x, y \in E} q(x, y) [F(\xi^{x,y}) - F(\xi)] + \sum_{x \in E} \int_S [F(\xi^{x|\sigma}) - F(\xi)] d\mu(\sigma),
\]

where \(F : S^E \to \mathbb{R}\), the configuration \(\xi^{x,y}\) in the first sum of (2.1) is given by

\[
\xi^{x,y}(a) = \begin{cases} 
\xi(y) & \text{if } a = x, \\
\xi(a) & \text{if } a \neq x,
\end{cases}
\]

and the configuration \(\xi^{a|\sigma}\) in the second sum of (2.1) is obtained by replacing the type of \(\xi\) at \(a\) with \(\sigma\). Notice that the first sum in (2.1) governs the voting mechanism of the voter model, while the second sum governs its mutation mechanism. Since the voting mechanism is irrelevant to the mutation mechanism, it will become convenient to handle the two sums separately and henceforth we write \(L^\mu_{\mathcal{VM}} = L_{\mathcal{VM}} + L_{\mu}\), where

\[
L_{\mathcal{VM}} = L^0_{\mathcal{VM}}
\]

and

\[
L_{\mu} F(\xi) = \sum_{x \in E} \int_S [F(\xi^{x|\sigma}) - F(\xi)] d\mu(\sigma).
\]

We consider two classes of test functions for the empirical measures of voter models. They will be used separately to characterize limits with respect to weak convergence or weak atomic convergence of empirical measures of voter models. To define these test functions, first we write

\[
\lambda(f) = \langle f, \lambda \rangle = \int_{S^k} f(\sigma_1, \cdots, \sigma_k) d\lambda(\sigma_1, \cdots, \sigma_k),
\]

for \(\lambda \in \mathcal{P}(S^k)\), \(f : S^k \to \mathbb{R}\) and \(k \in \mathbb{N}\), where the reference to \(k\) for \(\lambda(f)\) and \(\langle f, \lambda \rangle\) will remain implicit but should be clear from the context.

The first class of test functions consists of functions \(\phi\) of the form:

\[
\phi(\lambda) = \prod_{i=1}^k \langle f_i, \lambda \rangle
\]

(2.5)
for continuous functions $f_i : S \to \mathbb{R}$ and $k \in \mathbb{N}$. We set $\Phi_k$ to be the set of functions on $\mathcal{P}(S)$ taking the form (2.5) and $\Phi = \bigcup_{k \in \mathbb{N}} \Phi_k$. To facilitate the following computations, we also set, for a function $\phi$ as in (2.5),

$$
\phi_A(\lambda) = \prod_{i \in A} \langle f_i, \lambda \rangle \quad \text{and} \quad \Delta_A^\phi(\sigma, \tau) = \prod_{i \in A} [f_i(\sigma) - f_i(\tau)]
$$

(2.6)

for all $A \subseteq \{1, \ldots, k\}$, $\lambda \in \mathcal{P}(S)$ and $\sigma, \tau \in S$, with the convention that the products are identically equal to 1 if $A$ is empty. Notice that $\Delta_A^\phi(\sigma, \tau) \neq \Delta_A^\phi(\tau, \sigma)$ in general.

The introduction of the test functions in (2.5) is to facilitate the study of weak convergence of the empirical measures for voter models by the method of moments. If $\phi$ is as in (2.5) and $f_i$‘s are indicator functions of single types, then $\phi(\mathcal{m}(\xi))$ reduces to a product of moments of densities for (possibly) different types in $\xi$ (recall the notation $\mathcal{m}(\xi)$ in (1.1)). This fact should make evident our consideration of the following proposition, which characterizes dynamics of empirical measures for voter models. See also Section 3 for the characterization of Fleming–Viot processes by these test functions.

**Proposition 2.1.** For every $k \in \mathbb{N}$ and $\phi \in \Phi_k$ taking the form (2.5), we have

$$
L_{\text{VM}} \phi \circ \mathcal{m}(\xi) = \sum_{A : A \subseteq \{1, \ldots, k\}} \phi_A \circ \mathcal{m}(\xi) \sum_{x, y \in E} \pi(x)^{|A|} q(x, y) \Delta_A^\phi(\xi(y), \xi(x)),
$$

(2.7)

$$
L_{\mu} \phi \circ \mathcal{m}(\xi) = \sum_{A : A \subseteq \{1, \ldots, k\}} \phi_A \circ \mathcal{m}(\xi) \sum_{x \in E} \pi(x)^{|A|} \int_S \Delta_A^\phi(\sigma, \xi(x)) d\mu(\sigma)
$$

(2.8)

with the convention that a sum over an empty set is zero, where $\mathcal{m}$ is defined by (1.1) and $\phi \circ \mathcal{m}(\xi) = \phi(\mathcal{m}(\xi))$.

**Proof.** We start with the proof of (2.7). By the definition of $\xi^{x,y}$ in (2.2), we have, for all $f : S \to \mathbb{R}$,

$$
\langle f, \mathcal{m}(\xi^{x,y}) \rangle = \langle f, \mathcal{m}(\xi) \rangle + \pi(x)[f \circ \xi(y) - f \circ \xi(x)]
$$

since $f \circ \xi^{x,y}$ and $f \circ \xi$ only differ at site $x$ and the difference is $f \circ \xi(y) - f \circ \xi(x)$. (Here, $f \circ \xi(x) \equiv f(\xi(x))$.) It follows that

$$
\phi \circ \mathcal{m}(\xi^{x,y}) - \phi \circ \mathcal{m}(\xi)
$$

$$
= \prod_{i=1}^k \left( \langle f_i, \mathcal{m}(\xi) \rangle + \pi(x)[f_i \circ \xi(y) - f_i \circ \xi(x)] \right) - \phi \circ \mathcal{m}(\xi)
$$

$$
= \sum_{A : A \subseteq \{1, \ldots, k\}} \prod_{i \in A} \langle f_i, \mathcal{m}(\xi) \rangle \prod_{i \in A} \pi(x)[f_i \circ \xi(y) - f_i \circ \xi(x)] - \phi \circ \mathcal{m}(\xi)
$$

$$
= \sum_{A : A \subseteq \{1, \ldots, k\}} \phi_A \circ \mathcal{m}(\xi) \pi(x)^{|A|} \Delta_A^\phi(\xi(y), \xi(x)),
$$

(2.9)
where in the last equality we use the definition of $\phi$ and the notations in (2.6). We deduce from the last equality and (2.1) that

$$L_{VM}\phi \circ m(\xi) = \sum_{A: A \subseteq \{1, \ldots, k\}, |A| \geq 1} \phi_{A^c} \circ m(\xi) \sum_{x, y \in E} \pi(x)^{|A|} q(x, y) \Delta_{A}^\phi(\xi(y), \xi(x)).$$

In particular, all the summands on the right-hand side of (2.9) indexed by $A = \{i\}$ for $1 \leq i \leq k$ vanish since

$$\sum_{x, y \in E} \pi(x)^{|A|} q(x, y) \Delta_{A}^\phi(\xi(y), \xi(x)) = \sum_{x, y \in E} \pi(x)q(x, y)f_i \circ \xi(y) - \sum_{x, y \in E} \pi(x)q(x, y)f_i \circ \xi(x) = 0,$$

where the last equality follows from the fact that $\pi q = \pi$ and $q1 = 1$. The last two displays prove (2.7).

The proof of the required equality for $L_{\mu}\phi \circ m(\xi)$ in (2.8) is similar. By the definition of $L_{\mu}$ in (2.3), we have

$$L_{\mu}\phi \circ m(\xi) = \sum_{x \in E} \int_S [\phi \circ m(\xi^{x|\sigma}) - \phi \circ m(\xi)]d\mu(\sigma)$$

$$= \sum_{x \in E} \sum_{A: A \subseteq \{1, \ldots, k\}, |A| \geq 1} \phi_{A^c} \circ m(\xi)\pi(x)^{|A|} \int_S \Delta_{A}^\phi(\sigma, \xi(x))d\mu(\sigma),$$

which follows from the same calculation in the display for (2.9) if one replaces $\xi(y)$ with $\sigma$ from the second line on in that display and then integrates with respect to $d\mu(\sigma)$ over $S$. The foregoing equality proves (2.8).

In the next section, we will begin our proof for the weak convergence of empirical measures for voter models toward Fleming-Viot processes stated in (1.2). As discussed in Section 1, our method uses the well-posedness of the martingale problems for Fleming-Viot processes, which, roughly speaking, requires us to characterize only the first two moments of empirical measures for voter models. This direction will call for the following special cases of Proposition 2.1.

**Corollary 2.2.** (1) For $\phi$ as in (2.5) with $k = 1$, we have

$$L_{VM}\phi \circ m(\xi) = 0 \quad \text{and} \quad L_{\mu}\phi \circ m(\xi) = \langle A_{\mu}f_1, m(\xi) \rangle,$$

where

$$A_{\mu}f(\tau) = \int_S [f(\sigma) - f(\tau)]d\mu(\sigma).$$
For $\phi$ as in (2.5) with $k = 2$, we have

\[ L_{\text{VM}} \phi \circ m(\xi) = \sum_{x \neq y \in E} \pi(x)^2 q(x, y) \Delta_{\{1, 2\}}(\xi(y), \xi(x)), \]  
(2.12)

\[ L_\mu \phi \circ m(\xi) = \sum_{i=1}^{2} \langle A_\mu f_i, m(\xi) \rangle \prod_{j \neq i} \langle f_j, m(\xi) \rangle 
+ \pi_{\text{diag}} \langle f_1 f_2, \mu \rangle - \langle f_1, \mu \rangle \sum_{x \in E} f_2 \circ \xi(x) \pi(x)^2 
- \sum_{x \in E} f_1 \circ \xi(x) \pi(x)^2 \langle f_2, \mu \rangle + \mu(1) \sum_{x \in E} f_1 f_2 \circ \xi(x) \pi(x)^2, \]  
(2.13)

where $\pi_{\text{diag}} = \sum_{x \in E} \pi(x)^2$ and $f \circ \xi(x) = f(\xi(x))$.

Next we consider the following test functions for empirical measures of voter models:

\[ F_f(\xi) = \langle f, m(\xi)^{\otimes 2} \rangle = \sum_{x \neq y \in E} \pi(x) \pi(y) f(\xi(x), \xi(y)) \]  
(2.14)

for Borel measurable functions $f : S \times S \rightarrow \mathbb{R}$. These test functions $F_f$ will be used in Section 5 to investigate weak atomic convergence for empirical measures of voter models, where a criterion from [21] is invoked (see the proof of Theorem 5.1).

**Proposition 2.3.** For $F_f$ defined as in (2.14) with respect to a Borel measurable function $f : S \times S \rightarrow \mathbb{R}$, we have

\[ L_{\text{VM}} F_f(\xi) = \sum_{x \neq y \in E} \pi(x)^2 q(x, y) \left[ f(\xi(y), \xi(y)) - f(\xi(x), \xi(x)) \right] 
- \sum_{x \neq y \in E} \pi(x)^2 q(x, y) \left[ f(\xi(y), \xi(x)) + f(\xi(x), \xi(y)) - 2f(\xi(x), \xi(x)) \right] \]  
(2.15)

and

\[ L_\mu F_f(\xi) = \sum_{x \in E} \pi(x)^2 \int_S \left[ f(\sigma, \sigma) - f(\xi(x), \xi(x)) \right] d\mu(\sigma) 
- \sum_{x \in E} \pi(x)^2 \int_S \left[ f(\xi(x), \sigma) + f(\sigma, \xi(x)) - 2f(\xi(x), \xi(x)) \right] d\mu(\sigma) 
+ \sum_{x, y \in E} \pi(x) \pi(y) \int_S \left[ f(\xi(x), \sigma) + f(\sigma, \xi(y)) - 2f(\xi(x), \xi(y)) \right] d\mu(\sigma). \]  
(2.16)
Proof. We compute

\[ L_{VM}f(\xi) = \sum_{x,y \in E} q(x, y) \sum_{a,b \in E} \pi(a)\pi(b) \left[ f(\xi^{x,y}(a), \xi^{x,y}(b)) - f(\xi(a), \xi(b)) \right] \]

\[ = \sum_{x,y \in E} \sum_{a,b:a=x or b=x} q(x, y)\pi(a)\pi(b) \left[ f(\xi^{x,y}(a), \xi^{x,y}(b)) - f(\xi(a), \xi(b)) \right] \]

\[ = \sum_{x,y \in E} q(x, y)\pi(x)^2 \left[ f(\xi(y), \xi(y)) - f(\xi(x), \xi(x)) \right] \]

\[ + \sum_{x,y \in E} \sum_{b \neq x} q(x, y)\pi(x)\pi(b) \left[ f(\xi(y), \xi(b)) - f(\xi(x), \xi(b)) \right] \]

\[ + \sum_{x,y \in E} \sum_{a \neq x} q(x, y)\pi(a)\pi(x) \left[ f(\xi(a), \xi(y)) - f(\xi(a), \xi(x)) \right]. \]

The required equation (2.15) now follows from the preceding equality, if we apply again the fact that \( \pi q = \pi \) and \( qI = I \) to its last two terms. The proof of (2.16) is similar, and is left to the readers. \( \square \)

3 Fleming-Viot processes and empirical measures of voter models

We characterize Fleming-Viot processes by the following martingale-problem formulation. Recall the notations in (2.4), (2.6) and (2.11), and the classes of test functions \( \Phi_k \) and \( \Phi \) introduced in Section 2. We define an operator \( L^\mu_{FV} \) on \( \Phi \) by

\[ L^\mu_{FV}\phi(\lambda) = \frac{1}{2} \sum_{1 \leq i < j \leq k} \langle \Delta^n_{ij}^\phi, \lambda^\otimes 2 \rangle \prod_{\ell \neq i,j} \langle f_t, \lambda \rangle + \sum_{1 \leq i \leq k} \langle A_{ij} f_i, \lambda \rangle \prod_{\ell \neq i} \langle f_t, \lambda \rangle \]  

(3.1)

for \( \lambda \in \mathcal{P}(S) \) and \( \phi \in \Phi_k \) as in (2.5), and put \( L^0_{FV} = L^0_{FV} \) to be consistent with the analogous notation for generators of voter models. Then the \( \mu \)-Fleming-Viot process \( X \) can be characterized by the well-posed martingale problem: for all \( \phi \in \Phi \), the process

\[ \phi(X_t) - \phi(X_0) - \int_0^t L^\mu_{FV}\phi(X_s)ds \]  

(3.2)

is a continuous martingale (cf. [19, Section 10.4]).

Our program in the rest of this section is to obtain a quantitative version of the approximation:

\[ E_{\xi}[L_{VM}\phi \circ m(\xi_s)] \approx \text{constant} \cdot L^\mu_{FV}\phi(m(\xi)) \]  

(3.3)

for enough large \( s \) when suitable voting kernels are used. We will give a rigorous form of this approximation for \( \phi \in \Phi_2 \) that is adequate to obtain the weak convergence of empirical measures for voter models in Section 4, as well as a bound for the left-hand side of (3.3) to gain its control at ineligible times \( s \).
Before stating and proving these results we need a preliminary inequality (Proposition 3.1 below). It requires the standard duality which connects the voter model and a system of coalescing \( q \)-Markov chains \( \{X^x; x \in E\} \). Here, \( X^x \) are rate-1 \( q \)-Markov chains starting at \( x \in E \), and they move independently before meeting and together afterward. Let \( M_{x,y} = \inf\{t \geq 0; X^x_t = X^y_t\} \) be this meeting time. In Section 6, we present in detail the graphical construction of this duality relation. In particular, for any fixed \( t > 0 \) and \( x, y \in E \), the construction provides an explicit construction of \( \xi_t(x) \) and \( \xi_t(y) \) in terms of coalescing chains \( X^x \) and \( X^y \) started at \( x \) and \( y \), respectively, run for time \( t \), with mutation events occurring at rate \( \mu(1) \) along the paths of these chains. Here in Proposition 3.1 below and what follows, we write

\[
\mu(\Sigma) = \mu(\Sigma)^{(1)} \tag{3.4}
\]

with the convention that \( \mu(0) = 0 \) when \( \mu = 0 \), and \( \mathbb{E}_\xi \) and \( \mathbb{P}_\xi \) for expectation and probability of the voter model with generator \( L_{\mu_{\text{VM}}} \) (2.1) and initial state \( \xi \in S^E \), respectively. In addition, with respect to a system of coalescing \( q \)-chains \( \{X^x; x \in E\} \) as above, we write \( M_{x,y} = \inf\{t \geq 0; M_t^x = M_t^y\} \).

**Proposition 3.1.** Given \( f : S \times S \rightarrow \mathbb{R} \) satisfying \( f(\sigma, \sigma) \equiv 0 \) and \( \sup_{\sigma, \tau} |f(\sigma, \tau)| \leq 1 \), we have, for all \( \xi \in \{0,1\}^E \), \( x, y \in E \) and \( t \in \mathbb{R}_+ \),

\[
\left| \mathbb{E}_\xi [f(\xi_t(x), \xi_t(y))] - \mathbb{E} [f(\xi_t(X^x_t), \xi_t(X^y_t))] \right| \\
\leq C(1 - e^{-\mu(1)t}) \mathbb{P}(M_{x,y} > t) + C \mu(1) \int_0^t \mathbb{P}(M_{x,y} > s) ds \tag{3.5}
\]

for some universal constant \( C \).

The proof of Proposition 3.1 will be given in Section 6, where we use the graphical construction mentioned above. Roughly speaking, it comes from the following observation. In order for the difference

\[
f(\xi_t(x), \xi_t(y)) - f(\xi_0(X^x_t), \xi_0(X^y_t))
\]

to be nonzero one of the following events must occur: (a) \( M_{x,y} > t \) and no mutation events occur along the two paths before \( t \), or (b) \( M_{x,y} \leq t \) and at least one mutation event occurs along the paths before \( M_{x,y} \). The probability of (a) is bounded by the first term on the right-hand side of (3.5), and the probability of (b) is bounded by the expected number of mutation events before \( M_{x,y} \wedge t \), which is bounded by the second term on the right-side of (3.5).

Now we proceed to a rigorous form of (3.3). To compare the dynamics of empirical measures for voter models with the dynamics of Fleming-Viot processes, we first introduce some notation. For an irreducible transition kernel \( (E, q) \), let \( (q_t) \) be the semigroup of the rate-1 \( q \)-Markov chain on \( E \). Then we set

\[
d_E(t) = \max_{x \in E} \|q_t(x, \cdot) - \pi\|_{TV} \tag{3.6}
\]
for the maximal total variation distance of the semigroup \((q_t)\) from its stationary distribution \(\pi\), and consider the choice of mixing time:

\[
t_{\text{mix}} = \inf\left\{ t \geq 0; d_E(t) \leq (2e)^{-1} \right\}. \tag{3.7}
\]

Here in (3.6) \(\| \cdot \|_{TV}\) refers to the usual total variation distance. In addition, if \(q\) is reversible, we write \(g\) for the spectral gap of the voting kernel \(q\), which is the difference between the largest and the second largest eigenvalues of the symmetric matrix \(\pi(x)q(x, y)\) indexed by points of \(E\). To minimize the use of sum notation, we write \((V, V')\) for a random vector taking values in \(E \times E\), which is independent of \(\{X^x\}\) and the voter model, and has joint distribution given by

\[
P(V = x, V' = y) \equiv \frac{\pi(x)^2q(x, y)}{\pi_{\text{diag}}}
\]

(recall that \(\pi_{\text{diag}} = \sum_{x \in E} \pi(x)^2\)). Finally, \(C_\phi\) stands for a strictly positive constant, which may vary from line to line and depends only on a function \(\phi \in \Phi\).

**Proposition 3.2.** For \(\phi \in \Phi_2\) and \(s, t \in (0, \infty)\) with \(s < t\), we have the following two different estimates between the generators \(L^{VM}\) and \(L^{FV}\) where mutation is absent:

\[
\sup_{\xi \in S_E} \left| \mathbb{E}_\xi [L^{VM}\phi \circ m(\xi_t)] - 2\pi_{\text{diag}} P(M_{V,V'} > s)L^{FV}\phi(m(\xi)) \right|
\leq C_\phi \pi_{\text{diag}} P(M_{V,V} \in (s, t]) + C_\phi \pi_{\text{diag}} (1 - e^{-\mu(1)t})P(M_{V,V} > t)
+ C_\phi \pi_{\text{diag}} \mu(1) \int_0^t P(M_{V,V'} > r)dr + C_\phi d_E(t - s)\pi_{\text{diag}} P(M_{V,V'} > t), \tag{3.8}
\]

and

\[
\sup_{\xi \in S_E} \left| \mathbb{E}_\xi [L^{VM}\phi \circ m(\xi_t)] - 2\pi_{\text{diag}} P(M_{V,V'} > s)L^{FV}\phi(m(\xi)) \right|
\leq C_\phi \pi_{\text{diag}} P(M_{V,V} \in (s, t]) + C_\phi \pi_{\text{diag}} (1 - e^{-\mu(1)t})P(M_{V,V'} > t)
+ C_\phi \pi_{\text{diag}} \mu(1) \int_0^t P(M_{V,V'} > r)dr + C_\phi \pi_{\text{max}} e^{-g(t-s)}, \tag{3.9}
\]

where \(\pi_{\text{max}} = \max_{x \in E} \pi(x)\). We stress that the expectation \(\mathbb{E}\) and probability \(P\) in the foregoing two displays are for the voter model with generator \(L^{VM}_\mu\) (2.1).

The inequalities in Proposition 3.2 will be used to formalize the approximation (3.3) by making

\[
2\pi_{\text{diag}} P(M_{V,V'} > s) \longrightarrow 1 \tag{3.10}
\]

with appropriate choices of \(s\) and voting kernels. See the proof of Step 2 of Lemma 4.2 for further details.
Proof of Proposition 3.2. As in the proof of [11, Proposition 6.1], first we derive a preliminary estimate for $\mathbb{E}_\xi[L_{\text{VM}}\phi \circ \mathbf{m}(\xi)]$ which will be refined to obtain (3.8) and (3.9).

Now we use the explicit form (2.12) of $L_{\text{VM}}\phi \circ \mathbf{m}(\xi)$ for $\phi \in \Phi_2$ taking the form (2.5), Proposition 3.1 and the fact that $\Delta_{\{1,2\}}^\phi(\xi(x), \xi(x)) \equiv 0$. They give

$$
\mathbb{E}_\xi[L_{\text{VM}}\phi \circ \mathbf{m}(\xi_t)] = \pi_{\text{diag}} \mathbb{E} \left[ \Delta_{\{1,2\}}^\phi(\xi_t) \right]
$$

$$
= \pi_{\text{diag}} \mathbb{E} \left[ \Delta_{\{1,2\}}^\phi(X_t^V, Y^V_t); M_{V,V'} > s \right] + \pi_{\text{diag}} \varepsilon_0(t, \xi),
$$

(3.11)

where the term $\varepsilon_0(t, \xi)$ satisfies the inequality

$$
|\varepsilon_0(t, \xi)| \leq C_{\phi} \left( \mathbb{P}(M_{V,V'} \in (s, t]) + (1 - e^{-\mu(1)t}) \mathbb{P}(M_{V,V'} > t) \right)
$$

$$
+ \mu(1) \int_0^t \mathbb{P}(M_{V,V'} > r)dr.
$$

(3.12)

In the rest of the proof, we will consider two different estimates for the first term on the right-hand side of (3.11).

For the first estimate, we apply the Markov property of $(X^V, Y^V)$ at time $s$ to get

$$
\pi_{\text{diag}} \mathbb{E} \left[ \Delta_{\{1,2\}}^\phi(X_s^V, Y^V_s); M_{V,V'} > s \right]
$$

$$
= \pi_{\text{diag}} \sum_{x,y \in E} \mathbb{P}(X_s^V = x, Y^V_s = y, M_{V,V'} > s) \mathbb{E} \left[ \Delta_{\{1,2\}}^\phi(X^s_{t-s}, Y^s_{t-s}) \right]
$$

$$
= \pi_{\text{diag}} \sum_{x,y \in E} \mathbb{P}(X_s^V = x, Y^V_s = y, M_{V,V'} > s)
$$

$$
\times \left\{ \sum_{a,b \in E} [q_{t-s}(x,a)q_{t-s}(y,b) - \pi(a)\pi(b)] \Delta_{\{1,2\}}^\phi(\xi(a), \xi(b)) + 2L_{FV}\phi(\mathbf{m}(\xi)) \right\}
$$

$$
= \pi_{\text{diag}} \varepsilon_1(s, t, \xi) + 2\pi_{\text{diag}} \mathbb{P}(M_{V,V'} > s) L_{FV}\phi(\mathbf{m}(\xi)),
$$

(3.13)

where the second equality follows from the definition (3.1) of $L_{FV} = L_{FV}'$ and the definition of $\Delta_{\{1,2\}}^\phi$ in (2.6), and in the last equality the error term $\varepsilon_1(s, t, \xi)$ satisfies the inequality

$$
|\varepsilon_1(s, t, \xi)| \leq C_{\phi} d_E(t - s) \mathbb{P}(M_{V,V'} > s).
$$

(cf. [27, Proposition 4.5]). Applying (3.13) to (3.11), we obtain (3.8).

To obtain the second estimate (3.9), now we consider the difference

$$
\pi_{\text{diag}} \mathbb{E} \left[ \Delta_{\{1,2\}}^\phi(X_t^V, Y^V_t); M_{V,V'} > s \right] - 2\pi_{\text{diag}} \mathbb{P}(M_{V,V'} > s) L_{FV}\phi(\mathbf{m}(\xi))
$$

$$
= \pi_{\text{diag}} \mathbb{E} \left[ \Delta_{\{1,2\}}^\phi(X_t^V, Y^V_t)
$$

$$
- \sum_{x,y \in E} \pi(x)\pi(y) \Delta_{\{1,2\}}^\phi(\xi(x), \xi(y)); M_{V,V'} > s \right].
$$

(3.14)
Taking into account the expansion
\[
\Delta^\phi_{(1,2)}(\sigma, \tau) = f_1(\sigma)f_1(\tau) - f_1(\sigma)f_2(\tau) - f_1(\tau)f_2(\sigma) + f_2(\sigma)f_2(\tau)
\]
for \(\phi(\lambda) \equiv \langle f_1, \lambda \rangle \langle f_2, \lambda \rangle\), we see that (3.14) and Markov property imply
\[
\begin{align*}
&\left| \pi_{\text{diag}} \mathbb{E} \left[ \Delta^\phi_{(1,2)}(\xi(X^V_t), \xi(X^\xi_t); M_{V,V'} > s) \right] - 2\pi_{\text{diag}} \mathbb{P}(M_{V,V'} > s) L_{FV}\phi(m(\xi)) \right| \\
\leq & C_\phi \pi_{\text{diag}} \sum_{j,k \in \{1,2\}, W \in \{V,V'\}} \mathbb{E} \left[ |q_{t-s}(f_j^k \circ \xi)(X_s^W) - \pi(f^k_j \circ \xi)| \right] \\
\leq & C_\phi \pi_{\text{diag}} \sum_{j,k \in \{1,2\}, W \in \{V,V'\}} \mathbb{E} \left[ (q_{t-s}f_j^k \circ \xi(X_s^W) - \pi(f^k_j \circ \xi))^2 \right]^{1/2} \\
\leq & C_\phi \pi_{\text{diag}} \sum_{j,k = 1}^2 \left( \frac{\pi_{\text{max}}}{\pi_{\text{diag}}} \text{Var}_\pi(f_j^k) \right)^{1/2} e^{-g(t-s)},
\end{align*}
\]
where \(f_j^k\) is the \(k\)-th power of \(f_j\), \(\text{Var}_\pi(f) = \sum_{x \in E} (f(x) - \pi(f))^2 \pi(x)\), and the last inequality follows from the definition of \((V, V')\) and a standard variance bound for the mixing times of Markov chains [16, Lemma 2.4]. Applying the foregoing inequality to (3.11) gives (3.9). The proof is complete. \(\square\)

We close this section with a bound for empirical measures of voter models, which will be used to control the left-hand side of (3.3) at times \(s\) when we cannot validate (3.10). See the proof of Lemma 4.2 for further details.

**Proposition 3.3.** For \(\phi \in \Phi\) and \(t \in (0, \infty)\), it holds that
\[
\sup_{\xi \in S^E} \mathbb{E}_x \left[ |L_{VM\phi} \circ m(\xi(t))| \right] \leq C_\phi \pi_{\text{diag}} \mathbb{P}(M_{V,V'} > t)
+ C_\phi \pi_{\text{diag}} \mu(1) \int_0^t \mathbb{P}(M_{V,V'} > r) dr.
\]

**Proof.** To obtain (3.15), we first claim that for \(\phi \in \Phi\) as in (2.5),
\[
|L_{VM\phi} \circ m(\xi)| \leq C_\phi \sum_{x,y \in E} \pi(x)^2 q(x,y) \mathbbm{1}_{\{\xi(x) \neq \xi(y)\}}.
\]
To see this, notice that for all \(A \subseteq \{1, \ldots, k\}\) with \(|A| \geq 2\),
\[
\sum_{x,y \in E} \pi(x)^{|A|} q(x,y) |\Delta^\phi_{A}(\xi(x), \xi(y))| \leq C_\phi \sum_{x,y \in E} \pi(x)^2 q(x,y) \mathbbm{1}_{\{\xi(x) \neq \xi(y)\}},
\]
and so (3.16) follows from (2.7).
Second we can repeat the argument for (3.11) and obtain from Proposition 3.1 that, for all \(x, y \in E\),
\[
\sup_{\xi \in S^E} \mathbb{P}_x(\xi(x) \neq \xi(t)) \leq (C + 1) \mathbb{P}(M_{x,y} > t) + C \mu(1) \int_0^t \mathbb{P}(M_{x,y} > r) dr.
\]
Now (3.15) follows upon applying the foregoing inequality to (3.16). \(\square\)
4 Weak convergence of empirical measures for voter models

The goal of this section is to prove Theorem 4.1, which concerns weak convergence of empirical measures for voter models. Throughout this section and Section 5, we consider a sequence of \((E_n, q^{(n)}, \mu_n)\)-voter models with \(N_n = \#E_n \to \infty\). As before, \((E_n, q^{(n)})\) are irreducible and \(\mu_n\) are finite measures on the same type space \(S\).

We continue to use the notations introduced in Section 2 and 3, except that they now carry either subscripts ‘\(n\)’ or superscripts ‘\((n)\)’. We also need here the parameter \(\gamma_n\) to time-change the \((E_n, q^{(n)}, \mu_n)\)-voter model, which is chosen to be the expected first meeting times of two independent \(q^{(n)}\)-Markov chains starting from stationarity (see also [11, Theorem 2.2]). The measure-valued processes

\[
X_t^{(n)} = m(\xi_{\gamma_nt})
\]

for the \((E_n, q^{(n)}, \mu_n)\)-voter models are the central object of this section.

**Theorem 4.1.** Let \(\mathcal{P}(S)\) be equipped with the Prohorov metric. Suppose that

(i) \(\lim_{n \to \infty} \pi^{(n)}_{\text{diag}} = 0\),

(ii) \(\gamma_n \mu_n\) converges weakly to a finite measure \(\mu\) on \(S\),

(iii) \(X_0^{(n)} \xrightarrow{(d)} \tilde{X}_0\) in \(\mathcal{P}(S)\),

and one of the following conditions holds:

(iv-1) \(\lim_{n \to \infty} \gamma_n^{-1} \max t^{(n)}_{\text{mix}} = 0\),

(iv-2) the \(q^{(n)}\)-chains are reversible with \(\lim_{n \to \infty} \log (e \vee \gamma_n^{-1} \max t^{(n)}_{\text{mix}}) / \gamma_n \min t^{(n)}_{\text{mix}} = 0\).

If \(X\) is the \(\mu\)-Fleming-Viot process such that its initial condition has the same distribution as \(\tilde{X}_0\), then we have

\[
X^{(n)} \xrightarrow{(d)} X\quad \text{in}\ D(\mathbb{R}_+, \mathcal{P}(S))
\]

with respect to Skorokhod’s \(J_1\)-topology.

Let us set up some notation to facilitate the proof of Theorem 4.1. We write \(\mathcal{F}^{(n)}_t = \sigma(\xi_{\gamma_{ns}}; s \leq t)\) for \(t \in \mathbb{R}_+\), so that \((\mathcal{F}^{(n)}_t)\) is the natural filtration of the time-changed process \((\xi_{\gamma_{nt}})\). We decompose \(\phi(X^{(n)}_t)\), for any \(\phi \in \Phi\), into

\[
\phi(X^{(n)}_t) = \phi(X^{(n)}_0) + \phi(A^{(n)}_t) + \phi(M^{(n)}_t),
\]

15
where $A^{(n)}$ is defined by
\[ \phi(A_t^{(n)}) \equiv \gamma_n \int_0^t L_{\nu_n}^{\mu_n} \phi \circ m(\xi_{\gamma_n r}) dr \] (4.4)
and $M^{(n)}$ is by (4.3). Note that $\phi(M^{(n)})$ is a martingale by the definition of $\phi(A^{(n)})$ and the boundedness of $\phi$.

The following lemma is the first step of the proof of Theorem 4.1. It identifies the functional form of the quadratic variation for the empirical measure of a voter model in the limit of large $E_n$.

**Lemma 4.2.** Under the assumptions of Theorem 4.1, we have, for any $\phi_1(\lambda) = \langle f_1, \lambda \rangle, \phi_2(\lambda) = \langle f_2, \lambda \rangle \in \Phi_1$ for $f_1, f_2 \in C(S)$ and $t \in (0, \infty)$,
\[
\lim_{n \to \infty} \mathbb{E}^{(n)} \left[ \int_0^t \gamma_n L_{\nu_n}^{\mu_n} \phi_1 \circ m(\xi_{\gamma_n r}) dr - \int_0^t L_{\Phi_1}^{\mu_n} \phi_1(X_t^{(n)}) dr \right] = 0, 
\] (4.5)
\[
\lim_{n \to \infty} \mathbb{E}^{(n)} \left[ \int_0^t \gamma_n L_{\nu_n}^{\mu_n} \phi_2 \circ m(\xi_{\gamma_n r}) dr - \int_0^t L_{\Phi_2}^{\mu_n} \phi_2(X_t^{(n)}) dr \right] = 0, 
\] (4.6)
where $X^{(n)}$ under $\mathbb{E}^{(n)}$ has initial condition $X_0^{(n)}$ satisfying condition (iii) of Theorem 4.1.

**Proof.** We fix $t \in (0, \infty)$ throughout the following and divide the proof into Step 1–3. We prove (4.5) in Step 1 and (4.6) in Step 3.

**Step 1.** To see (4.5), we note that by Corollary 2.2 (1) and (3.1),
\[
\int_0^t \gamma_n L_{\nu_n}^{\mu_n} \phi_1 \circ m(\xi_{\gamma_n r}) dr - \int_0^t L_{\Phi_1}^{\mu_n} \phi_1(X_t^{(n)}) dr = \int_0^t \langle \gamma_n A_{\mu_n} - A_{\mu}, f_1, X_t^{(n)} \rangle dr.
\]
The required convergence follows upon applying condition (ii) of Theorem 4.1 to the right-hand side of the foregoing equality.

**Step 2.** We will show that it is possible to choose a sequence $(s'_n)$ such that $s'_n \nrightarrow \infty$, $s'_n = o(\gamma_n)$ and
\[
\varepsilon_n = \sup_{\xi \in S^{\mathbb{E}_n}} \left| \mathbb{E}_\xi^{(n)} \left[ \gamma_n L_{\nu_n}^{\mu_n} \phi_1 \circ m(\xi_{\gamma_n r}) - L_{\Phi_1}^{\mu_n} \phi_1 \circ m(\xi) \right] \right| \to 0 \quad (4.7)
\]
for $\delta_n = s'_n/\gamma_n$. As in the proof of the analogous fact given in [11, Lemma 6.2], a key role is played by the following limiting properties of the meeting time laws $\mathbb{P}^{(n)}(M_{V,V'} \in \cdot)$. If the conditions (i) and either of (iv-1) or (iv-2) in Theorem 4.1 hold, then
\[
\lim_{n \to \infty} 2\gamma_n \pi_{\text{diag}}^{(n)} \int_0^t \mathbb{P}^{(n)}(M_{V,V'} > \gamma_n r) dr = 1 - e^{-t} \quad \forall \ t \geq 0 \quad (4.8)
\]
(see [11, Theorem 4.1] and the proof of [11, (6.13)]). Furthermore, the argument proving [11, 6.14], which assumes only conditions (i) and (iv-1) of Theorem 4.1, shows how to obtain a sequence \((s'_n)\) such that \(\delta_n = s'_n/\gamma_n \rightarrow 0\), \(s'_n/t_{\text{mix}}^{(n)} \rightarrow \infty\) so that

\[
d_{E_n}(s'_n) \leq \exp(-[s'_n/t_{\text{mix}}^{(n)}]) \xrightarrow{n \to \infty} 0
\]

(see [27, Section 4.5] for this inequality) and also

\[
2\gamma_n \pi^{(n)}_{\text{diag}} \mathbb{P}^{(n)}(M_{V,V'} > s'_n) \xrightarrow{n \to \infty} 1 \quad \& \quad 2\gamma_n \pi^{(n)}_{\text{diag}} \mathbb{P}^{(n)}(M_{V,V'} \in (s'_n, 2s'_n]) \xrightarrow{n \to \infty} 0.
\]

To see our claim \((4.7)\), we set \(s = s'_n\) and \(t = 2s'_n\), and use the bound in \((3.8)\). After rearrangements, we have

\[
\varepsilon_n \leq C_{\phi_1 \phi_2} \left[ 2\gamma_n \pi^{(n)}_{\text{diag}} \mathbb{P}^{(n)}(M_{V,V'} > s'_n) - 1 \right]
+ C_{\phi_1 \phi_2} \gamma_n \pi^{(n)}_{\text{diag}} \mathbb{P}^{(n)}(M_{V,V} \in (s'_n, 2s'_n])
+ C_{\phi_1 \phi_2} \gamma_n \pi^{(n)}_{\text{diag}} \mathbb{P}^{(n)}(M_{V,V'} > s'_n) d_{E_n}(s'_n)
+ C_{\phi_1 \phi_2} \frac{1 - e^{-\mu_1(1)2s'_n}}{\mu_n(1)} \gamma_n \pi^{(n)}_{\text{diag}} \mathbb{P}^{(n)}(M_{V,V} > 2s'_n) \cdot \delta_n \gamma_n \mu_n(1)
+ C_{\phi_1 \phi_2} \gamma_n \mu_n(1) \cdot \gamma_n \pi^{(n)}_{\text{diag}} \int_0^{2s_n} \mathbb{P}^{(n)}(M_{V,V'} > \gamma_r) dr.
\]

Here, the first three terms tend to 0 by \((4.9)\) and \(d_{E_n}(s'_n) \to 0\). The fourth term tends to 0 by \((4.9)\), condition (ii) of Theorem 4.1, and \(\delta_n \to 0\). The fifth term tends to 0 by condition (ii) of Theorem 4.1, \((4.8)\), and \(\delta_n \to 0\). Replacing (iv-1) of Theorem 4.1 with (iv-2) in the same theorem and using \((3.9)\) instead of \((3.8)\), the proof of \((4.7)\) follows from a similar argument (see the second part of the proof of [11, Lemma 6.2], especially \((6.17)\) there).

**Step 3.** We prove \((4.6)\) in this step. Recall the definitions \((2.1)\) of \(L^n_{V,M} = L_{V,M} + L^n_{\mu}\) and \((3.1)\) of \(L^n_{V} = L_{V} + L^n_{\mu}\). We handle the mutation contributions to \((4.6)\) first; more precisely, we will show that

\[
\lim_{n \to \infty} \mathbb{E}^{(n)} \left[ \left| \int_0^t \gamma_n L^n_{\mu} \phi_1 \phi_2 \circ m(\xi_{\gamma_n r}) dr - \int_0^t L^n_{\mu} \phi_1 \phi_2(X^{(n)}_r) dr \right| \right] = 0.
\]

The foregoing equality can be obtained by an approximation of the difference of the integrands pointwise in \(\xi\). Indeed by Corollary 2.2 (2), for any \(\xi \in S^{E_n}\) this difference
\begin{align*}
\gamma_n L_{\mu_n} \phi_1 \phi_2 \circ m(\xi) &= -2 \sum_{i=1}^{2} \langle A_{\mu_n} f_i, m(\xi) \rangle \prod_{\ell \neq i} \langle f_\ell, m(\xi) \rangle \\
&= \sum_{i=1}^{2} \langle (\gamma_n A_{\mu_n} - A_{\mu}) f_i, m(\xi) \rangle \prod_{\ell \neq i} \langle f_\ell, m(\xi) \rangle \\
&+ \pi_{\text{diag}}^{(n)}(f_1 f_2, \gamma_n \mu_n) - \langle f_1, \gamma_n \mu_n \rangle \sum_{x \in E_n} f_2 \circ \xi(x) \pi^{(n)}(x) \\
&- \sum_{x \in E_n} f_1 \circ \xi(x) \pi^{(n)}(x)^2 \langle f_2, \gamma_n \mu_n \rangle + \gamma_n \mu_n(\mathbb{1}) \sum_{x \in E_n} f_1 f_2 \circ \xi(x) \pi^{(n)}(x)^2.
\end{align*}

The last equality is enough to obtain (4.10) by conditions (i) and (ii) of Theorem 4.1. In the rest of Step 3, we handle the voting mechanism behind (4.6) and show that

$$\lim_{n \to \infty} \mathbb{E}^{(n)} \left[ \left| \int_0^t \gamma_n L_{\text{VM}} \phi_1 \phi_2 \circ m(\xi_{\gamma_n r}) dr - \int_0^t L_{\text{FV}} \phi_1 \phi_2 (X_r^{(n)}) dr \right| \right] = 0. \quad (4.11)$$

Notice that the foregoing equality and (4.10) thus give (4.6) by (2.1) and (3.1). To obtain (4.11), we first recall the sequence $\delta_n = s'/\gamma_n \to 0$ for $(s'_n)$ chosen in Step 2 and use Proposition 3.3 to get

$$\mathbb{E}^{(n)} \left[ \left| \int_0^{2\delta_n} \gamma_n L_{\text{VM}} \phi_1 \phi_2 \circ m(\xi_{\gamma_n r}) dr - \int_0^{2\delta_n} L_{\text{FV}} \phi_1 \phi_2 (X_r^{(n)}) dr \right| \right] \leq C_{\phi_1 \phi_2} \left( \gamma_n \pi_{\text{diag}}^{(n)} + \gamma_n^2 \pi_{\text{diag}}^{(n)} \mu_n(\mathbb{1}) \delta_n \right) \int_0^{2\delta_n} \mathbb{P}^{(n)}(M_{V,V'} > \gamma_n r) dr + C_{\phi_1 \phi_2} \delta_n, \quad (4.12)$$

which tends to zero as $n \to \infty$ by the validity of (4.8) and condition (ii) of Theorem 4.1.

With (4.12) in hand, we complete the proof of (4.11) by proving

$$\lim_{n \to \infty} \mathbb{E}^{(n)} \left[ \left| \int_{2\delta_n}^t \gamma_n L_{\text{VM}} \phi_1 \phi_2 \circ m(\xi_{\gamma_n r}) dr - \int_{2\delta_n}^t L_{\text{FV}} \phi_1 \phi_2 (X_r^{(n)}) dr \right| \right] = 0. \quad (4.13)$$

To get the foregoing limit, we will need the estimates:

$$\limsup_{n \to \infty} \sup_{\xi \in S^{E_n}} \gamma_n \mathbb{E}_\xi^{(n)} \left[ \left| L_{\text{VM}} \phi_1 \phi_2 \circ m(\xi_{2\gamma_n}) \right| \right] < \infty,$$

$$\sup_{n \in \mathbb{N}} \sup_{\xi \in S^{E_n}} \int_0^t \gamma_n \mathbb{E}_\xi^{(n)} \left[ \left| L_{\text{VM}} \phi_1 \phi_2 \circ m(\xi_{\gamma_n r}) \right| \right] dr < \infty, \quad (4.14)$$

$$\lim_{n \to \infty} \sup_{\xi \in S^{E_n}} \int_0^{2\delta_n} \gamma_n \mathbb{E}_\xi^{(n)} \left[ \left| L_{\text{VM}} \phi_1 \phi_2 \circ m(\xi_{\gamma_n r}) \right| \right] dr = 0,$$

which follow from the martingale-difference argument employed in the proof of [11, Theorem 2.2]. The first of these estimates follows from (4.7) and the fact the $L_{\text{FV}} \phi_1 \phi_2$
is bounded, and the last two follow from Proposition 3.3, (4.8), condition (ii) of Theorem 4.1, and $\delta_n \to 0$.

Fix $n$ and $\xi \in S^{E_n}$. Now if we define

$$H_n(s) = \gamma_n L_{VM} \phi_1 \phi_2 \circ m(\xi_{\gamma n}) - E_{\xi}^{(n)} [\gamma_n L_{VM} \phi_1 \phi_2 \circ m(\xi_{\gamma n}) | \mathcal{F}_{s-2\delta_n}^{(n)}], \quad s \geq 2\delta_n,$$

then the expectation in (4.13) is bounded above by

$$E_{\xi}^{(n)} \left[ \left( \int_{2\delta_n}^t H_n(s) ds \right)^2 \right]^{1/2} + E_{\xi}^{(n)} \left[ \int_{2\delta_n}^t E_{\xi}^{(n)} [\gamma_n L_{VM} \phi_1 \phi_2 \circ m(\xi_{\gamma n}) | \mathcal{F}_{s-2\delta_n}^{(n)}] - L_{FV} \phi_1 \phi_2 (X_{s-2\delta_n}^{(n)}) ds \right]$$

$$+ \int_{2\delta_n}^t (L_{FV} \phi_1 \phi_2 (X_{s-2\delta_n}^{(n)}) - L_{FV} \phi_1 \phi_2 (X_{s}^{(n)})) ds \right].$$

Each of these terms above tends to $0$ for the following reasons. The third term tends to $0$ because $L_{FV} \phi_1 \phi_2$ is bounded and $\delta_n \to 0$. The second term tend to $0$ by the Markov property and (4.7). The proof that the first term tends to $0$ starts with the observation that since $E_{\xi}^{(n)} [H_n(s)H_n(r)] = 0$ whenever $s-r > 2\delta_n$, we have

$$E_{\xi}^{(n)} \left[ \left( \int_{2\delta_n}^t H_n(s) ds \right)^2 \right] = 2 \int_{2\delta_n \leq r \leq s \leq t} E_{\xi}^{(n)} [H_n(s)H_n(r)1_{\{r>s-2\delta_n\}}] ds dr.$$

The argument showing the last integral tends to $0$ is straightforward given the estimates in (4.14) above, but is somewhat lengthy. Since it is essentially the same argument starting at [11, (6.20)], we refer the reader there for details.

Hence, (4.11) holds by (4.12) and (4.13). The proof is complete. \qed

The following lemma is our second step toward the proof of Theorem 4.1 and obtains the necessary $C$-tightness of the empirical measures under consideration for convergence to a Fleming-Viot process.

**Lemma 4.3.** Under the assumptions of Theorem 4.1, the sequence of laws of $\{X^{(n)}\}$ is $C$-tight as probability measures on $D(\mathbb{R}_+, \mathcal{P}(S))$.

**Proof.** In this proof, we show that for $\phi \in \Phi_1$ with $\phi(\lambda) = \langle f, \lambda \rangle$ for $f \in \mathcal{C}(S)$, both the sequences of laws of $\{\phi(A^{(n)})\}$ and $\{\phi(M^{(n)})\}$ are $C$-tight as probability measures on $D(\mathbb{R}_+, \mathbb{R})$. The $C$-tightness of these sequences will be enough for the present lemma by Jakubowski’s theorem (e.g. [34, Theorem II.4.1]), since the type space $S$ is assumed to be compact and condition (iii) of Theorem 4.1 is in force.

We make two observations in order to prove the $C$-tightness of the sequence of laws of $\{\phi(A^{(n)})\}$. First, for every $0 \leq s < t < \infty$,

$$|\phi(A_t^{(n)}) - \phi(A_s^{(n)})| \leq \gamma_n \int_s^t |L_{VM} \phi \circ m(\xi_{\gamma n r})| dr + C_\phi \gamma_n \mu_n(1)(t-s) \quad (4.15)$$
by the definition (2.1) of $L^n_{VM}$. Next, we observe that (3.15) gives

$$\sup_{\xi \in S^\Phi_n} \gamma_n \int_0^t \mathbb{P}^{(n)}[|L_{VM} \phi \circ m(\xi_{\gamma_n r})|] dr \leq C_\phi \gamma_n \pi^{(n)}_{\text{diag}} \int_0^t \mathbb{P}(M_{V,V'} > \gamma_n r) dr$$

$$+ C_\phi \gamma_n^2 \pi^{(n)}_{\text{diag}} \mu(1)t \int_0^t \mathbb{P}^{(n)}(M_{V,V'} > \gamma_n r) dr. \quad (4.16)$$

Then it is readily checked by the Markov property of voter models that for all $K \in \mathbb{N}$,

$$\lim_{\theta \to 0} \limsup_{n \to \infty} \sup_{S,T: S \leq T \leq S + \theta} \mathbb{P}^{(n)}\left[|\phi(A_T^{(n)}) - \phi(A_S^{(n)})|\right] = 0, \quad (4.17)$$

where $S, T$ range over all $(\mathcal{F}_t^{(n)})$-stopping times bounded by $K$. In more detail, one conditions on $\mathcal{F}_S^{(n)}$ when bounding the expectation in the foregoing display for a fixed pair $(S, T)$ and then handles an expectation for the voter model started at $\xi_S$ by (4.15) and (4.16), which requires conditions (i), (ii) and (iv-1) or (iv-2) of Theorem 4.1 and the use of (4.8). Since $\phi$ is a bounded function, (4.17) is enough to fulfill Aldous’s condition on $C$-tightness for the sequence of laws of $\{\phi(A^{(n)})\}$ (cf. [24, Theorem VI.4.5]).

To obtain the $C$-tightness of the sequence of laws of $\{\phi(M^{(n)})\}$, we first observe that the predictable quadratic variations of $\phi(M^{(n)})$ is given explicitly by

$$\langle \phi(M^{(n)}) \rangle_t = \gamma_n \int_0^t \left( L_{VM}^{\mu_n} \phi^2 \circ m(\xi_{\gamma_n r}) - 2 \phi \circ m(\xi_{\gamma_n r}) L_{VM}^{\mu_n} \phi \circ m(\xi_{\gamma_n r}) \right) dr. \quad (4.18)$$

The foregoing equation follows since $\Phi$ is closed under multiplication and $\phi(M^{(n)})$ and $\phi^2(M^{(n)})$ are both $(\mathcal{F}_t^{(n)})$-martingales (cf. [19, Exercise II.29]). We apply the boundedness of $\phi$ and (4.16) to (4.18), and argue as in the case of $\phi(A^{(n)})$ that (4.17) holds with $\phi(A_T^{(n)})$ and $\phi(A_S^{(n)})$ replaced by $\langle \phi(M^{(n)}) \rangle_T$ and $\langle \phi(M^{(n)}) \rangle_S$, respectively. By [24, Theorem VI.4.5] again, we have the $C$-tightness of the sequence of laws of $\{\phi(M^{(n)})\}$. Then, since $\phi(M^{(n)})$ has jumps bounded by $C_{\phi} \pi^{(n)}_{\text{max}} \to 0$ by condition (i) of Theorem 4.1, [24, Theorem VI.4.13, Proposition VI.3.26] apply and we obtain the required $C$-tightness of the sequence of laws of $\{\phi(M^{(n)})\}$. The proof is complete.

We are now ready to prove the first main result of this paper.

**Proof of Theorem 4.1.** By Skorohod’s representation (cf. [19, Theorem 3.1.8]), we may assume by Lemma 4.3 and a change of probability spaces that $\{X^{(n)}\}$ converges in distribution to some $X$ taking values in $C(\mathbb{R}_+, \mathcal{P}(S))$. Then for any $\phi \in \Phi_1$ with $\phi(\lambda) = \langle f, \lambda \rangle$ for $f \in \mathcal{C}(S)$, we deduce from Lemma 4.2 and (4.18) that $\phi(X_t) - \phi(X_0) - \int_0^t L_{FV} \phi(X_r) dr$ is a continuous martingale with quadratic variation

$$\int_0^t \left( L_{FV}^\mu \phi^2(X_r) - 2 \phi(X_r) L_{FV}^\mu \phi(X_r) \right) dr.$$ 

More precisely, to justify the above form of quadratic variation for $\phi(X)$, we need the fact that $x \mapsto \int_0^t L_{FV}^\mu \phi(x_r) dr$ is a bounded continuous function from $D(\mathbb{R}_+, \mathcal{P}(S))$.

---

20
into $D(\mathbb{R}_+,\mathbb{R})$ for any $\phi \in \Phi$, and the uniqueness of quadratic variations for martingales. Then by integration by parts for continuous semimartingales and the preceding martingale characterization of $\phi(X)$ for $\phi \in \Phi_1$, we deduce that $X$ is a continuous $\mathcal{P}(S)$-valued process satisfying the same martingale problem for the $\mu$-Fleming-Viot process over $\Phi$ as recalled in (3.2) (or see [33, p.2]). This completes the proof of Theorem 4.1.

5 Weak atomic convergence of empirical measures for voter models

In this section, we proceed to the weak atomic convergence of empirical measures for voter models in the limit of a large state space. Let us briefly recall the setup in [21, Section 2] for weak atomic convergence of finite measures and its implications. Let $d$ be a metric on the compact type space $S$. Fix a continuous function $J : \mathbb{R}_+ \to [0, 1]$ such that $J(0) = 1$ and $J \equiv 0$ on $[1, \infty)$. Let $\rho$ be the Prohorov metric on the set $\mathcal{M}_f(S)$ of finite measures on $S$, and define a metric $\rho_a$ on $\mathcal{M}_f(S)$ by

$$\rho_a(\lambda, \nu) = \rho(\lambda, \nu) + \sup_{0 < \varepsilon \leq 1} \left| \int_{S^2} J \left( \frac{d\sigma \wedge \tau}{\varepsilon} \right) d\lambda^\otimes(\sigma, \tau) - \int_{S^2} J \left( \frac{d\sigma \wedge \tau}{\varepsilon} \right) d\nu^\otimes(\sigma, \tau) \right|. \tag{5.1}$$

This metric $\rho_a$, finer than $\rho$, still keeps $\mathcal{M}_f(S)$ a complete separable space and generates the same Borel sigma-field as $\rho$ does (see [21, Lemma 2.3 and p.5]).

To see the role of the second term on the right-hand side of (5.1), notice that corresponding to every finite measure $\lambda$ on $S$ is an atomic measure for the distributions of the atoms of $\lambda$ defined by

$$\lambda^* \doteq \sum_{\sigma \in S} \lambda(\{\sigma\})^2 \delta_\sigma.$$

With the foregoing definition, the readers may note that the difference between the double-integral terms in (5.1) for small enough $\varepsilon > 0$ means the approximate difference between $\lambda^*(S)$ and $\nu^*(S)$ through the mollifier $J(\cdot/\varepsilon)$. In fact, it can be shown that $\rho_a(\lambda_n, \lambda) \to 0$ if and only if $\rho(\lambda_n, \lambda) \to 0$ and $\lambda_n^*(S) \to \lambda^*(S)$ (see [21, Lemma 2.2]), where the last convergence (for the “starred-measures”) has the obvious interpretation that there is no loss of atoms in the limit.

Below we study limit theorems of the empirical measures for finite voter models (they are probability measures on $S$), and now the space $\mathcal{P}(S)$ is equipped with the metric $\rho_a$ finer than the Prohorov metric $\rho$ underlying Theorem 4.1. For this purpose and since $(\mathcal{P}(S), \rho_a)$ is a closed subspace of $(\mathcal{M}_f(S), \rho_a)$, we may and will restrict our application of $\rho_a$ to $\mathcal{P}(S)$ from now on.

Our second main result in this paper proves the weak atomic convergence of empirical measures for finite voter models.

21
**Theorem 5.1.** Let \( \{X^{(n)}\} \) be a sequence of empirical measures for \((E_n, q^{(n)}, \mu_n)\)-voter models time-changed by \( \gamma_n \) as in (4.1). Assume that the sequence \( \{X^{(n)}\} \) converges weakly to a \( \mu \)-Fleming-Viot process \( X \) on \( D(\mathbb{R}_+, \mathcal{P}(S)) \) for \( \mathcal{P}(S) \) equipped with the Prohorov metric.

Now equip the space \( \mathcal{P}(S) \) with the metric \( \rho_a \) instead. Then \( X \) has almost all sample paths in \( C(\mathbb{R}_+, \mathcal{P}(S)) \). In addition, if the sequence of laws of \( \{X^{(n)}\} \) converges to the law of \( X_0 \) as probability measures in \( \mathcal{P}(S) \) and we have

\[
\lim \sup_{\varepsilon \downarrow 0^+} \sup_{\tau \in S} \lim_{n \to \infty} \gamma_n \mu_n \{ \sigma \in S; 0 < d(\sigma, \tau) \leq \varepsilon \} = 0, \tag{5.2}
\]

then the sequence of laws of \( \{X^{(n)}\} \) converges as probability measures on \( D(\mathbb{R}_+, \mathcal{P}(S)) \) to the law of the \( \mu \)-Fleming-Viot process \( X \).

**Proof.** That \( X \) has almost all sample paths in \( C(\mathbb{R}_+, \mathcal{P}(S)) \) follows from [19, Theorem 3.1]. For the second assertion, we will show that for every \( T, \delta > 0 \), there exists \( \varepsilon > 0 \) such that

\[
\mathbb{P}^{(n)} \left( \sup_{0 \leq t \leq T} F_{f_\varepsilon}(\xi_{\gamma_n t}) \geq \delta \right) \leq \delta \tag{5.3}
\]

for all large enough \( n \), where \( F_{f_\varepsilon} \) is as defined in (2.14) for

\[
f_\varepsilon(\sigma, \tau) = J \left( \frac{d(\sigma, \tau)}{\varepsilon} \right) - 1 \{d(\sigma, \tau) = 0\}. \]

Since

\[
F_{f_\varepsilon}(\xi_{\gamma_n t}) = \int_{S^2} J \left( \frac{d(\sigma, \tau)}{\varepsilon} \right) dX_t^{(n)}(\sigma, \tau) - (X_t^{(n)})^*(S)
\]

by definition, the bound (5.3) fulfills the condition of [21, (2.21)], and so implies the required weak atomic convergence of the sequence of laws of \( \{X^{(n)}\} \) toward \( X \).

The proof of (5.3) relies on some facts which we now state. First, since \( f_\varepsilon \) is symmetric and nonnegative, and vanishes on the diagonal, it follows from Proposition 2.3 that

\[
L_{\lambda}^{\mu_n} F_{f_\varepsilon}(\xi) \leq 2 \sum_{x \in E_n} \pi^{(n)}(x) \int_S f_\varepsilon(\sigma, \xi(x)) d\mu_n(\sigma).
\]

Hence, we have

\[
F_{f_\varepsilon}(\xi_{\gamma_n t}) = F_{f_\varepsilon}(\xi_0) + \int_0^t \gamma_n L_{\lambda}^{\mu_n} F_{f_\varepsilon}(\xi_{\gamma_n r}) dr + M_t 
\leq F_{f_\varepsilon}(\xi_0) + \int_0^t 2 \gamma_n \sum_{x \in E_n} \pi^{(n)}(x) \int_S f_\varepsilon(\sigma, \xi_{\gamma_n r}(x)) d\mu_n(\sigma) dr + M_t, \tag{5.4}
\]

where \( M \) is a martingale with \( M_0 = 0 \), and so the right-hand side of (5.4) defines a nonnegative submartingale. Second, the map

\[
\lambda \mapsto \left( \int_{S^2} J \left( \frac{d(\sigma, \tau)}{\varepsilon} \right) d\lambda \otimes^2(\sigma, \tau) - \lambda^\ast(S) \right) \wedge 1 \tag{5.5}
\]

22
is a bounded continuous function on $\mathcal{P}(S)$ by [6, Theorem 1.2.8] and [21, Lemma 2.2], and we have

$$
\lim_{\varepsilon \searrow 0+} \left( \int_{S^2} J \left( \frac{d(\sigma, \tau)}{\varepsilon} \right) d\lambda^\otimes_2(\sigma, \tau) - \lambda^* (S) \right) = 0, \quad \forall \lambda \in \mathcal{P}(S), \tag{5.6}
$$

as already discussed before the present theorem in an informal manner.

We are ready to prove (5.3). Fix $T, \delta > 0$. By the assumed weak atomic convergence of $X^{(n)}_0$ to $X_0$ in distribution, the bounded continuity of the map (5.5) and (5.6), it holds that for any given $\varepsilon > 0$,

$$
\mathbb{E}^{(n)}[F_{\varepsilon}(\xi_0)] \leq \frac{\delta^2}{2} \tag{5.7}
$$

for all large enough $n$. In addition, thanks to (5.2) and the fact that $f_\varepsilon(\sigma, \tau)$ is supported on $\{(\sigma, \tau) \in S \times S; 0 < d(\sigma, \tau) \leq \varepsilon\}$ with $|f_\varepsilon| \leq 1$, we can choose $\varepsilon > 0$ such that

$$
\sup_{\xi \in S^E_n} \gamma_n \sum_{x \in E_n} \pi^{(n)}(x) \int_S f_\varepsilon(\sigma, \xi(x)) d\mu_n(\sigma) \leq \frac{\delta^2}{4T}, \tag{5.8}
$$

for all large $n$. Now by (5.4) and an application of Doob’s weak $L^1$-inequality to the nonnegative submartingale on the right-hand side of (5.4), we deduce from (5.7) and (5.8) that with respect to the $\varepsilon > 0$ chosen for (5.8),

$$
\mathbb{P}^{(n)} \left( \sup_{0 \leq t \leq T} F_{\varepsilon}(\xi_{\gamma_n t}) \geq \delta \right) \leq \frac{1}{\delta} \left( \mathbb{E}^{(n)}[F_{\varepsilon}(\xi_0)] + \mathbb{E}^{(n)} \left[ \int_0^T 2\gamma_n \sum_{x \in E_n} \pi^{(n)}(x) \int_S f_\varepsilon(\sigma, \xi_{\gamma_n s}(x)) d\mu_n(\sigma) ds \right] \right) \leq \delta,
$$

for all large enough $n$. The last inequality proves (5.3), and the proof is complete. □

As an application of Theorem 5.1, we consider the convergence of atom-size point processes for voter models when mutation is absent. We recall the coalescing Markov chains $(X^x)$, and in the following write $N_n = \#E_n$,

$$
\tilde{C}_j^{(n)} = \inf \{ t \geq 0; |\{X^x_t; x \in E_n\}| = j \}, \quad 1 \leq j \leq N_n,
$$

and $Z_1, Z_2, \ldots$ for a sequence of independent exponential variables with $\mathbb{E}[Z_j] = 1/(j^2)$.

**Theorem 5.2.** Equip $\mathcal{P}(S)$ with the metric $\rho_a$. Let $\{X^{(n)}\}$ be a sequence of empirical measures for $(E_n, q^{(n)}, 0)$-voter models time-changed by $\gamma_n$ as in (4.1), which converges weakly to a Fleming-Viot process $X$ without mutation.

Suppose also that for each $n \in \mathbb{N}$, the types under the initial condition of the $(E_n, q^{(n)}, 0)$-voter model are all distinct almost surely and it holds that

$$
\frac{\tilde{C}_j^{(n)}}{\gamma_n} \xrightarrow{(d)} \sum_{i=j+1}^{\infty} Z_i, \quad \forall j \in \mathbb{N}. \tag{5.9}
$$
Then for every continuous function $f : [0, 1] \rightarrow \mathbb{R}$, the process
\begin{equation}
\sum_{i=1}^{\infty} f(a_i(X_s)), \quad s \in (0, \infty),
\end{equation}
is continuous, and for every fixed $t \in (0, \infty)$,
\[
\left( \sum_{i=1}^{\infty} f(a_i(X_{s}^{(n)})) ; \ s \geq t \right) \xrightarrow{d_{n \rightarrow \infty}} \left( \sum_{i=1}^{\infty} f(a_i(X_{s})) ; \ s \geq t \right)
\]
as probability measures on $D([t, \infty), \mathbb{R})$.

The convergence in (5.9) under appropriate conditions is proven in [32, Theorem 1.1, Theorem 1.2], resolving an open problem in [4]. These conditions are enough (applying Theorems 4.1 and 5.1) for the weak convergence of $\{X^{(n)}\}$ to the Fleming-Viot process without mutation as required in Theorem 5.2. See also [11, Section 2] for related results in terms of the Wright-Fisher diffusion.

**Remark 5.3.** (1) Implicit in the conclusion of Theorem 5.2 is the fact that (5.10) is a finite sum for all $s > 0$ almost surely.

(2) As particular applications of Theorem 5.2, we obtain the weak convergence of the entropy processes and diversity processes associated with the voter models under consideration (cf. the definitions in (1.3) and (1.4)).

**Proof of Theorem 5.2.** For $\lambda \in \mathcal{P}(S)$ with masses of its atoms arranged in the decreasing order $a_1(\lambda) \geq a_2(\lambda) \geq \cdots$, we define
\[
S_L^f(\lambda) = \sum_{i=1}^{L \wedge \mathcal{N}(\lambda)} f(a_i(\lambda)), \quad L \in \mathbb{N} \cup \{\infty\},
\]
where $\mathcal{N}(\lambda) \in \mathbb{Z}_+ \cup \{\infty\}$ is the number of atoms of $\lambda$. In the following, we may assume that $X^{(n)} \rightarrow X$ a.s. in $D(\mathbb{R}_+, \mathcal{P}(S))$ by a change of probability spaces and Skorokhod’s representation (cf. [19, Theorem 3.1.8]). Since $X$ takes values in $C(\mathbb{R}_+, \mathcal{M}_f(S))$ by Theorem 5.1 where $\mathcal{P}(S)$ is equipped with $\rho_a$, it follows from [19, Theorem III.10.1] that almost surely,
\begin{equation}
\rho_a(X^{(n)}_{t}), X_{t} \xrightarrow{n \rightarrow \infty} 0 \quad \forall \ t \in \mathbb{R}_+.
\end{equation}

**Claim 1.** We have
\begin{equation}
\lim_{L \rightarrow \infty} \left( \mathbb{P}(\mathcal{N}(X_{t}) > L) + \limsup_{n \rightarrow \infty} \mathbb{P}(X_{t}^{(n)} > L) \right) = 0.
\end{equation}

To see (5.12), we note that for all $L \in \mathbb{N}$,
\[
\mathbb{P}(\mathcal{N}(X_{t}) > L) \leq \mathbb{P}(a_{L+1}(X_{t}) > 0) \leq \liminf_{n \rightarrow \infty} \mathbb{P}(a_{L+1}(X_{t}^{(n)}) > 0),
\]
24
where the last inequality follows from (5.11) and [21, Lemma 2.5]. We observe that $a_{L+1}(X_t^{(n)}) > 0$ implies that the number of distinct types under $\xi_{\gamma_n t}$, that is $\#\{\xi_{\gamma_n t}(x); x \in E_n\}$ (with $\{\xi_{\gamma_n t}(x); x \in E_n\}$ regarded as a set), is at least $L + 1$ under $P^{(n)}$. Also, we observe from duality (Section 6) that $(\xi_{\gamma_n t}(x); x \in E_n)$ and $(\xi_0(X_{\gamma_n t}^x)); x \in E_n)$ have the same distribution (see (6.1)). Since all of the coordinates of $\xi_0$ under $P^{(n)}$ are distinct by assumption, applying these two observations to the last inequality gives

$$\lim_{L \to \infty} \mathbb{P}(\mathbb{N}(X_t) > L) \leq \lim_{L \to \infty} \lim_{n \to \infty} \mathbb{P}\left(\hat{\gamma}_{L+1}^{(n)} \geq \gamma_{\gamma_n t}\right) = \lim_{L \to \infty} \mathbb{P}\left(\sum_{j=L+2}^{\infty} Z_j \geq t\right) = 0,$$

where the first equality follows from (5.9). Similarly,

$$\lim_{L \to \infty} \limsup_{n \to \infty} \mathbb{P}(\mathbb{N}(X_t^{(n)}) > L) = 0.$$

The last two displays prove our claim (5.12).

**Claim 2.** We have (1)

$$(a_1(X^{(n)}), a_2(X^{(n)}), \cdots) \overset{a.s.}{\to} (a_1(X), a_2(X^{(n)}), \cdots). \quad (5.13)$$

in $D(\mathbb{R}_+, \mathbb{R}_+^N)$, where $\mathbb{R}_+^N$ is endowed with the metric $((x_n), (y_n)) \mapsto \sum_{n=1}^{\infty} \frac{|x_n - y_n|^1}{2^n}$, and (2) each $a_j(X)$ takes values in $C(\mathbb{R}_+, \mathbb{R}_+)$ almost surely.

To see (1), we notice that $\lambda \mapsto (a_1(\lambda), a_2(\lambda), \cdots) : M(S) \to \mathbb{R}_+^N$ is continuous by [21, Lemma 2.5]. Hence, by [19, Proposition 3.6.5 or Exercise 3.13], the almost-sure convergence of $X^{(n)}$ to $X$ in $D(\mathbb{R}_+, \mathcal{P}(S))$ implies (5.13). For (2), the continuity of $a_j(X)$ follows from [21, Lemma 2.5] and the fact that $X$ takes values in $C(\mathbb{R}_+, \mathcal{P}(S))$ almost surely (see the beginning of the present proof).

We are ready to prove Theorem 5.2. First we note that by the continuity of $s \mapsto a_j(X_s)$ in Claim 2, $s \mapsto S_{L}^{f}(X_s)$ is continuous on $[t, \infty)$ for any $L' \in \mathbb{N} \cup \{\infty\}$, which proves the first assertion of the theorem in particular. For the second assertion, we consider the following inequality: for every $t, T, \delta, L > 0$ with $t < T$,

$$\mathbb{P}\left(\sup_{s \in [t, T]} |S_{L}^{f}(X_s^{(n)}) - S_{L}^{f}(X_s)| > \delta\right) \leq \mathbb{P}\left(\sup_{s \in [t, T]} |S_{L}^{f}(X_s^{(n)}) - S_{L}^{f}(X_s)| > \delta\right) + \mathbb{P}(\mathbb{N}(X_t^{(n)}) > L) + \mathbb{P}(\mathbb{N}(X_t) > L), \quad (5.14)$$

which follows from the fact that $s \mapsto \mathbb{N}(X_s^{(n)})$ and $s \mapsto \mathbb{N}(X_s^{(n)})$ are finite and decreasing on $[t, \infty)$ almost surely by Claim 1, (5.13) in Claim 2 and the assumption that mutation is absent. To handle the first term on the right-hand side of (5.14),
we use both (1) and (2) in Claim 2 and standard properties of convergence of càdlàg functions to continuous functions (cf. [19, Section 3.10]) to get

$$\limsup_{n \to \infty} \mathbb{P} \left( \sup_{s \in [t,T]} |S_{f}^{l}(X_{s}^{(n)}) - S_{f}^{l}(X_{s})| > \delta \right) = 0.$$  

Claim 1 is able to handle the other two terms on the right-hand side of (5.14). Hence, by (5.14), we obtain

$$\lim_{n \to \infty} \mathbb{P} \left( \sup_{s \in [t,T]} |S_{f}^{\infty}(X_{s}^{(n)}) - S_{f}^{\infty}(X_{s})| > \delta \right) = 0,$$

which is enough to obtain the required convergence (cf. [19, Section 3.10]). We have proved our assertion for the atom-size point processes for the voter models under consideration. The proof is complete. \hfill \Box

6 Duality

In this section, we discuss the duality between multi-type voter models with mutation and coalescing Markov chains and prove Proposition 3.1. A similar treatment of the duality can be found in, for example, [23] for noisy voter models.

6.1 Graphical representation

First let $S_{x}^{x}$ and $\{U_{x}^{x}; k \geq 1\}$, for $x \in E$ and $k \geq 1$, be independent such that $S_{x}^{x}$ are $E$-valued with distribution $\mathbb{P}(S_{x}^{x} = y) \equiv q(x,y)$, and $U_{x}^{x}$’s are the arrival times of a rate-1 Poisson process; these $S_{x}^{x}$ and $U_{x}^{x}$ will be used to describe the $(E, q, 0)$-voter model where mutation is absent. To incorporate mutation with respect to $\mu$ satisfying $\mu(1) > 0$, we let $M_{x}^{x}$ and $\{V_{x}^{x}; k \geq 1\}$, for $x \in E$ and $k \geq 1$, be independent such that $M_{x}^{x}$ are i.i.d. $S$-valued with law $\overline{\mu}$, where $\overline{\mu} = \mu/\mu(1)$ as before, and $V_{x}^{x}$’s are the arrival times of a rate-$\mu(1)$-Poisson process. Moreover, $S_{x}^{x}, U_{x}^{x}, M_{x}^{x}, V_{x}^{x}$ are independent.

Now, given an initial condition $\xi \in S^{E}$, we have a version of a $(E, q, \mu)$-voter model which is defined as a pure-jump process with updating times $U_{x}^{x}$’s and $V_{x}^{x}$’s. At the times $U_{x}^{x}$, we draw an arrow at the space-time point $(x, U_{x}^{x})$ pointing to the space-time point $(S_{x}^{x}, U_{x}^{x})$, which means informally that site $x$ adopts the type at site $S_{x}^{x}$, and set $\xi_{t}(x) = \xi_{t-}(S_{x}^{x})$. At the mutation times $t = V_{x}^{x}$, we set $\xi_{t}(x) = M_{x}^{x}$.

To establish the duality, at any fixed time $t > 0$, first we reverse time and identify a family of $q$-coalescing Markov chains $\{X_{x,t}; x \in E\}$ which keep track of the genealogy of type propagation of the $(E, q, 0)$-voter model without mutation. We set $X_{0}^{x,t} \equiv x$ and then let $X_{s}^{x,t}$ trace out a path going backward in time down to the starting time of the voter model, following the arrows defined in the previous paragraph. Here and below, “backward” is in terms of the time progression of the voter model. More precisely, if $\{U_{k}^{x}; k \in \mathbb{N}\} \cap (0, t) = \emptyset$, we put $X_{s}^{x,t} = x$ for $s \in [0, t]$; otherwise, we
single out the last update defined by \((S^x, U^x)\) for the voter model without mutation by choosing \(k_0 = \max\{k \geq 1; U_k^x < t\}\), and set
\[
X_{s,t}^x = x \quad \text{for } s \in (0, t - U_{k_0}^x) \quad \text{and} \quad X_{t-U_{k_0}^x} = S_{k_0}^x.
\]

We repeat this construction starting at \((X_{t-U_{k_0}^x}^x, t-U_{k_0}^x)\) going backward in time, thus defining \(X_{s,t}^x\) for \(s\) up to \(t\) by an induction on the time intervals \([U_{k_0-1}^x, U_{k_0}^x], ..., [0, U_1^x]\).

It should be plain that for fixed \(t\), \(X_{s,t}^x\) are \(q\)-Markov chains by the reversibility of Poisson processes, and their coalescence after pairwise meeting follows from the use of the arrows.

The duality between the \((E, q, \mu)\)-voter model and the \(q\)-coalescing Markov chains \(\{X_{s,t}^x; x \in E, t \geq 0\}\) can be described as follows. We introduce \(\Pi_t = \{(y, V_k^y); y \in E, V_k^y \leq t\}\), which consists of all space-time points where mutation events occur up to time \(t\). Then we consider mutation events in terms of the type propagation genealogy of the \((E, q, 0)\)-voter model without mutation up to time \(t\), or equivalently, in terms of the union of space-time trajectories of \(X_{s,t}^x\) for \(x \in E\). If the chain \(X_{s,t}^x\) does not encounter a mutation event in \(\Pi_x\) throughout its trajectory in the sense that \((X_{s,t}^x, t-s) \notin \Pi_t\) for all \(s \in [0,t]\), we put \(e(x,t) = \infty\). Otherwise, we consider the first mutation event on the trajectory of \(X_{s,t}^x\). It corresponds to the last mutation event along the unique space-time “ancestral line” of type propagation under the voter-model dynamics without mutation, which leads to the type at site \(x\) and time \(t\), and finalizes the type being transported to the destination \((x,t)\). Therefore we choose \(y\) and \(k\) satisfying \(X_{s,t-V_k^y} = y\) and \((X_{s,t}^x, t-s) \notin \Pi_t\) for \(s < t - V_k^y\). Set \(e(x,t) = t - V_k^y\) and \(M(x,t) = M_k^y\) which give the time spent by \(X_{s,t}^x\) before finding that mutation event and the type of the associated mutant, respectively. Then we see that the \((E, q, \mu)\)-voter model with initial condition \(\xi\) defined above by \(S^x, U^x, M^x, V^x\) satisfies the equation
\[
\xi_t(x) = M(x,t)\mathbb{1}_{e(x,t) \leq t} + \xi(X_{s,t}^x)\mathbb{1}_{e(x,t) > t} \quad \forall x \in E \tag{6.1}
\]
almost surely for each fixed \(t\), which gives the required duality.

### 6.2 Proof of Proposition 3.1

To see how (3.5) follows from (6.1), we work with the partition \(\{A_j\}_{1 \leq j \leq 4}\) defined by
\[
A_1 = \{e(x,t) \land e(y,t) > t\},
A_2 = \{M_{x,y} < e(x,t) \land e(y,t) \leq t\},
A_3 = \{e(x,t) \land e(y,t) \leq M_{x,y} \leq t\},
A_4 = \{e(x,t) \land e(y,t) \leq t < M_{x,y}\}.
\]

Then we consider the differences
\[
\mathbb{E} \left[ f(\xi_t(x), \xi_t(y)); A_j \right] - \mathbb{E} \left[ f(\xi(X_{s,t}^x), \xi(X_{s,t}^y)); A_j \right]\tag{6.2}
\]
for $1 \leq j \leq 4$. For $j = 1$, there is no mutation throughout the trajectories of $X_t^{x,t}$ and $X_t^{y,t}$, and so $\xi_t(x) = \xi_t(X_t^{x,t})$ and $\xi_t(y) = \xi_t(X_t^{y,t})$. For $j = 2$, the two terms in the above display are both zero, since the two chains $X_t^{x,t}$ and $X_t^{y,t}$ coalesce before the first mutation events on their trajectories, which are the same as a result. In other words, for $j = 1, 2$, the above difference is zero. For $j = 3$, we write $e_1$ and $e_2$ for two independent exponential variables with mean one, and obtain

$$
\left| \mathbb{E} \left[ f(\xi_t(x), \xi_t(y)); A_3 \right] - \mathbb{E} \left[ f(\xi_t(X_t^{x,t}), \xi_t(X_t^{y,t})); A_3 \right] \right| \\
\leq P(e(x, t) \wedge e(y, t) < M_{x,y} < t) \\
\leq \int_0^t P(e_1 \wedge e_2 \leq s)P(M_{x,y} \in ds) \leq 2\mu(1) \int_0^t P(M_{x,y} > s)ds,
$$

where the second inequality follows from the independence $\{X_t^z; z \in E\} \perp \perp \{V_t^z; z \in E\}$ and the reversibility of Poisson processes. For $j = 4$, the same reason applies and we get

$$
\left| \mathbb{E} \left[ f(\xi_t(x), \xi_t(y)); A_4 \right] - \mathbb{E} \left[ f(\xi_t(X_t^{x,t}), \xi_t(X_t^{y,t})); A_4 \right] \right| \leq (1 - e^{-2\mu(1)t})P(M_{x,y} > t).
$$

The required inequality (3.5) follows by putting together these observations for the terms in (6.2) for $1 \leq j \leq 4$.
