ABSTRACT: Endotoxin is a highly toxic stimulator originated from the outer membrane of Gram-negative bacteria, which should be monitored sensitively and selectively for human health concerns. Traditional detection methods mainly rely on limulus amoebocyte lysate assay. However, it suffers drawbacks like the narrow detection range, and the results may be environment-dependent. In this work, we have developed a sensitive electrochemical biosensor for endotoxin assay. Peptide is first designed as specific recognition element toward endotoxin. Graphene oxide and DNA-modified gold nanoparticles are then used to enhance the electrochemical signal. The analytical performances are excellent with the limit of detection as low as 0.001 EU mL\(^{-1}\). This method has also been successfully applied in endotoxin assay in complex biological samples, which may have great potential use.

INTRODUCTION

Endotoxin is the main ingredient of the outer membrane of Gram-negative bacteria.\(^ {1,5} \) It acts as an extremely strong stimulator of innate immunity. Although it is beneficial at low concentrations, higher levels of endotoxin may cause symptoms like diarrhea, fever, multi organism failure, septic shock, and even death.\(^ {5} \) Exposure to endotoxin may occur through injection, dialysis, and polluted drinking water.\(^ {3} \) For example, dialysis patients are typically exposed to an annual 20 000 to 30 000 L of dialysis fluid, and the opportunity to experience an inflammation due to endotoxin contamination is significantly increased.\(^ {6} \) Considering the health risks of endotoxin, sensitive and convenient methods for endotoxin assay is critical and have attracted much attention.\(^ {7,8} \)

Although there have been well-established methods for the determination of endotoxin like the limulus amoebocyte lysate (LAL) assay as the golden method, many drawbacks should be overcome.\(^ {9} \) For instance, the linear range of LAL assay is narrow and the detection result is highly pH and temperature dependent. The detection of endotoxin can also be interfered by beta-glucan. Therefore, the development of enzyme-free assays should be emphasized. Different affinity molecules have been explored including aptamer,\(^ {10} \) peptide,\(^ {11} \) protein,\(^ {12} \) polymycin B,\(^ {13} \) and so on. In addition, many nanomaterials have also been employed for the generation and amplification of obtained signals.\(^ {14,15} \) For example, An and Jang immobilized a specific aptamer on glass for optical sensing and separation of endotoxin.\(^ {16} \) Lim et al. employed peptide-assembled graphene oxide in a fluorescent sensing system for sensitive detection of endotoxin.\(^ {17} \) Brosel-Oliu et al. fabricated a label-free impedimetric sensor for endotoxin assay based on concanavalin A recognition.\(^ {18} \) However, because of the increasing demands for endotoxin assay, there still exists an urgent need for more convenient, sensitive, and reliable methods for the practical detection of endotoxin.

In this work, we have integrated peptide-assembled graphene oxide and DNA modified gold nanoparticles (AuNPs) in an electrochemical sensing system for endotoxin assay. The thiol group of the peptide is able to bind to gold, localizing AuNPs on the electrode surface. The labeled ferrocene (Fc) molecules offer intense electrochemical responses. However, in the presence of endotoxin, specific interaction between endotoxin and peptide releases the thiol-containing peptide away from the electrode and the recorded signal of Fc is decreased. This novel method achieves a wide linear range from 0.005 to 1 EU mL\(^{-1}\) with a quite low limit of detection (LOD) of 0.001 EU mL\(^{-1}\).

RESULTS AND DISCUSSION

Detailed sensing principle is illustrated in Scheme 1. Generally, a glassy carbon electrode is first modified with negatively charged graphene oxide. The positively charged endotoxin binding peptide (pI = 2) is able to be absorbed on the electrode via electrostatic interactions. The specific recognition overcomes the potential interference like beta-glucan, nanoparticles, and so on. The thiol group of cysteine at the C-
terminal of the peptide allows the attachment of AuNPs on the electrode surface via gold–sulfur chemistry. Because Fc-labeled DNA probe is previously modified on the surface of AuNPs, significant Fc response could be recorded. Nevertheless, the peptide can be released from the graphene oxide by interacting with target endotoxin, negatively charged AuNPs cannot be facilely localized on the electrode, and the electrochemical signal is reduced. By analyzing the peak current of the electrochemical system, the initial endotoxin level can be evaluated. The proposed method has several merits including high selectivity and high sensitivity. The applied peptide not only allows specific recognition but also helps recruit numerous electrochemical species. The high sensitivity is attributed to two aspects. First, the good electric-conductivity of graphene oxide and AuNPs promise the electrochemical response with high intensity; second, because of the large specific area of AuNPs, a huge number of DNA molecules which are labeled with Fc are loaded on each AuNP, which assist the improvement of the sensitivity.19

The adsorption of AuNPs on graphene oxide can be intuitively determined by transmission electron microscopic (TEM) images. Sphere AuNPs can be observed with the diameter about 13 nm (Figure 1A). Without the assembled peptide, nearly no AuNPs can be decorated on the surface of graphene oxide because of electrostatic repulsion (Figure 1B). On the contrary, the added peptide provides abundant thiols for specific gold–sulfur interaction and a large number of AuNPs can thus be located on the graphene oxide nanosheets (Figure 1C). These results demonstrate that the peptide in this work not only functions as the recognition element but also helps the localization of AuNPs with electrochemical species.

We have further studied the effect of endotoxin on the electrochemical system. As depicted in Figure 2, the square wave voltammetry (SWV) curves of graphene oxide modified electrode before and after the assembly of peptide show no current peaks of Fc. After the capture of AuNPs, a strong peak is observed. However, if endotoxin exists in the sensing system, the disassociation of the peptide makes the immobilization of AuNPs impossible and the Fc signal disappears. The SWV responses demonstrate the feasibility of the system for endotoxin assay.

To achieve the best analytical performances, we have optimized the reaction times. Longer incubation of AuNPs with the electrode and longer incubation time of endotoxin with the peptide contribute to more adequate localization of Fc and release of the peptide. Also, the peak currents reach saturation after 90 and 10 min, respectively (Figure 3). Therefore, we have chosen the reaction times in the following quantitative experiments. As shown in Figure 4a, with larger...
The amount of endotoxin, the SWV peak intends to be decreased. Detailed relationship between the variation of peak current and the endotoxin concentration is summarized in Figure 4b. A linear range is found to be 0.005 to 1 EU mL$^{-1}$ with the equation of $y = 22.04 + 8.71x$, in which $x$ is the logarithmic endotoxin concentration and $y$ is the decreased SWV peak current. LOD is calculated as low as 0.001 EU mL$^{-1}$ based on 3 standard deviation (SD)/slope of calibration. The average relative SD is less than 10%, which is satisfactory. The analytical performances of this method are also excellent after compared with some representative reports (Table 1).

| turbidimetry   | kinetic turbidimetric LAL assay | 0.01               | Lonza BioScience |
| DPV            | $p$-nitroaniline-based LAL assay | 0.01               | 23         |
| DPV            | peptide-based capture and assay | 0.04               | 24         |
| amperometry    | electrochemical LAL assay     | 0.03               | 9          |
| elastography   | elastography-based LAL assay  | 0.002              | 25         |
| amperometry    | redox cycling in a nanocavity using the LAL reagent | 0.0005 | 26 |
| substitutional stripping voltammetry | $p$-aminophenol conjugated peptide | 0.0005 | 27 |
| SWV            | peptide/GO and Fe-modified AuNPs | 0.001              | this work  |

The selectivity of this assay is then evaluated by detecting SWV peaks in the presence of several potential coexisting interferences. The results shown in Table 2 imply that after employing bovine serum albumin (BSA), ligase, phi29 DNA polymerase, glucose, random peptide, immunoglobulin G (IgG), glutathione (GSH), some cations, and AuNPs, the electrochemical responses are similar with the blank case. After being spiked with a certain amount of endotoxin, the peak decreases significantly, demonstrating the specific interaction between the released peptide and target endotoxin. To test the practical utility of this method, we have further spiked standard endotoxin into Dulbecco’s modified eagle medium (DMEM) and serum samples. The detected values are listed in Table 3, which indicate that the complicated samples do not interfere...
Table 2. Selectivity Investigation: Detected Peak Currents of Potential Interferents Before and After being Spiked with Endotoxin

| samples          | peak current (μA) | peak current after spiking endotoxin (μA) |

accurate detection of endotoxin. The recoveries are from 94.0 to 110.0% and all relative errors are no larger than 5%.

**CONCLUSIONS**

In summary, we have fabricated a sensitive and selective electrochemical method for endotoxin assay combining peptide-modified graphene oxide and DNA-modified AuNPs. Because of excellent electric-conductivity of graphene oxide and AuNPs, significant electrochemical response can be obtained. The specificity of this method relies on the peptide-based recognition. The method achieves high sensitivity and it can be practically utilized for endotoxin assay in complicated biological samples, which has potential use for endotoxin monitoring in near future.

**EXPERIMENTAL SECTION**

**Materials and Instruments.** Endotoxin was obtained from Chinese Horseshoe Crab Reagent Manufactory (Xiamen) Co., Ltd. (China). BSA, glucose, GSH, gold(III) chloride trihydrate (HAuCl\(_4\)·3H\(_2\)O), tris(2-carboxyethyl)phosphine hydrochloride, and ethylenediaminetetraacetic acid were purchased from Sigma-Aldrich (USA). Ligase and phi29 DNA polymerase were from New England Biolabs Ltd. (Beijing, China). IgG was purchased from Sino Biological Inc. (China). DMEM was purchased from Gibco (Gaithersburg, USA). Graphene oxide was purchased from Nanjing XF-NANO Materials Tech. Co., Ltd. (Nanjing, China). The endotoxin binding peptide was chosen according to a previous report, in which Suzuki et al. selected the peptide using the phage-display method. The oligonucleotide was synthesized and purified by Sangon Biotech Co., Ltd. (Shanghai, China). The specific sequence was 5’-ferrocene-TCCATGTACCTT-3’ SH. Human serum samples were obtained from local hospital (Suzhou, China). The other chemicals or reagents were of analytical grade as received.

**Preparation of DNA Modified AuNPs.** Bare AuNPs were synthesized by means of citrate reduction of H\(_2\)AuCl\(_4\) according to a previous report. First, 100 mL of H\(_2\)AuCl\(_4\) solution (0.01%, w/v) and 3.5 mL of trisodium citrate solution (1%, w/v) were prepared. Second, trisodium citrate was added to H\(_2\)AuCl\(_4\) refluxing solution under stirring and boiling for 15 min. Third, the mixture was stirred for another 30 min before cooled down to room temperature. Next, 30 μM DNA probe was prepared in 10 μM phosphate buffer with 0.25 M NaCl (pH 7.4). DNA was then blended with AuNPs with the ratio of 1:9. After 1 min, the solution was adjusted to pH 3.0 using citrate buffer. Excess reagents were then removed by centrifuging at 12 000 rpm for 30 min. After that, the precipitate was redispersed.

**Preparation of Peptide-Modified Electrode.** The substrate glassy carbon electrode (3 mm) was pretreated with piranha solution (98% H\(_2\)SO\(_4\)/30% H\(_2\)O\(_2\) = 3:1) for about 5 min (Caution: highly corrosive). Next, the electrode was carefully rinsed and polished on PS000 silicon carbide paper to a mirror-like surface. After sonicated in ethanol and distilled water, respectively, the electrode was incubated with 10 μL of graphene oxide (500 mg L\(^{-1}\)) and then dried overnight at room temperature. The modified electrode was further treated with 2 μM peptide for 15 min in order to achieve the assembly of the peptide on the electrode surface.

**Quantiﬁcation of Endotoxin.** Standard endotoxin with a series of concentrations was prepared and the peptide-modiﬁed electrode was immersed in the solution for 10 min. Subsequently, the electrode was rinsed and then incubated with DNA-modiﬁed AuNPs for 90 min.

**Electrochemical Measurement.** We applied an electrochemical analyzer (CHI660D, CH Instruments) for all electrochemical experiments. A three-electrode system was employed, which was consisted of the peptide-modiﬁed electrode as the working electrode, a platinum auxiliary electrode, and a saturated calomel reference electrode. SWV was carried out in 20 mM Tris-HCl (pH 7.4) containing 140 mM NaCl and 5 mM MgCl\(_2\).
