(draft of March 25, 2022)

We establish the relationship between distribution and fragmentation functions and the structure functions appearing in the cross section of polarized 1-particle inclusive deep-inelastic scattering. We present spectator model evaluations of these structure functions focusing on the case of an outgoing spin-$\frac{1}{2}$ baryon. Distribution functions obtained in the spectator model are known to fairly agree at low energy scales with global parameterizations extracted, for instance, from totally inclusive DIS data. Therefore, we expect it to give good hints on the functional dependence of the structure functions on the scaling variables $x_B$, $z$ and on the transverse momentum of the observed outgoing hadron, $P_{h\perp}$. Presently, this dependence is not very well known, but experiments are planned in the near future.

\section{I. INTRODUCTION}

Totally inclusive deep-inelastic scattering (DIS) in the past years provided us with rather precise knowledge of the distribution functions of the proton and the neutron, helping us to understand their inner structure and raising questions yet unanswered. Semi-inclusive DIS displays even richer characteristics. Detecting at least one of the hadrons produced in the high-energy scattering process and measuring its momentum, one is then sensitive not only to the distribution of partons inside the target hadron, but also to the mechanism of hadronization, through which a quark gives rise to a jet of new hadrons. We are then able to measure not only the distribution functions, but also the so-called fragmentation functions. Neither the distribution nor the fragmentation functions can be calculated from first principles within perturbative QCD, because they belong to the non-perturbative realm of bound states. Therefore, models are required.

If only the dominant light-cone component of the momentum of the outgoing hadron is measured, its transverse components being integrated over, then the structure functions appearing in cross-sections will be products of a distribution and a fragmentation function. The already established knowledge of the distribution functions enables one to extract the shape of the fragmentation functions (cf. \cite{1}) and to compare it with other results coming from different experiments, such as electron-positron annihilation.

On the other hand, if we manage to measure the transverse momentum of the outgoing hadron we have the opportunity to study some new interesting distribution and fragmentation functions. In particular, already to leading order in an expansion in powers of $\frac{1}{Q}$ we have access to chiral odd

\addcontentsline{toc}{section}{I. INTRODUCTION}
and time-reversal odd functions, as well as functions related to the transverse momentum carried by quarks relative to their parent hadrons momentum. These functions are presently considered to be very interesting and their experimental measurement is in progress (HERMES, COMPASS, RHIC). The only major inconvenience of dealing with cross sections differential in the transverse momentum of the outgoing hadron is that the structure functions are no more simple products of a distribution and a fragmentation function, but rather convolutions of those.

In this context model evaluations of the structure functions can be very useful. The spectator model proved to be in qualitative agreement with the known (transverse momentum integrated) distribution and fragmentation functions evolved at low energies. Therefore, we expect it to give reasonable estimates for the convolution integrals in semi-inclusive DIS, provided that the inclusion of transverse momentum of partons does not spoil factorization properties, as it is usually assumed.

We are aware that our results cannot be considered as precise predictions of experimental quantities, because of the limitations and the simplicity of the model.

The model incorporates only valence quark distribution and fragmentation, neglecting the presence of sea-quarks, gluons and evolution. Therefore, it is supposed to reproduce the shape of the valence-quark distribution and fragmentation at a low energy scale, which is not known a priori. To give an estimate of this scale, one can compare the total momentum carried by quarks as given by the spectator model with the same quantity as given by parameterizations of the distribution functions at a known energy scale. Such a comparison suggests that the spectator model is valid at an energy scale of about 0.2-0.3 GeV.

In principle, the results we obtain need to be evolved to higher energy scales by means of evolution equations for a final comparison with experiment. Evolution equations for transverse momentum dependent functions are not yet known. In this article, therefore, we refrain from taking into account radiative corrections. Nevertheless, we are confident to describe correctly the main features and properties of the structure functions at low (intrinsic) transverse momentum, since perturbative corrections are expected to affect mainly the high transverse momentum tails of these functions.

The spectator model is a semi-phenomenological model, which relies mainly on the idea of describing the hadron as an ensemble of a free parton (struck in the scattering process) and a fictitious, unphysical particle, the spectator, with the right quantum numbers.

The model, at least in its present version, cannot describe time-reversal odd functions, since it does not incorporate final state interactions. On the other hand, the advantages of the model resides in the fact that it is simple, it is covariant and it gives a clear estimate of the distribution of partonic transverse momentum. Last but non least, the model can be treated in wide parts analytically. Some numerical integrations are required only when the cross section is kept differential also in the transverse momentum of the produced hadron.

In Sec. II we briefly review the general formalism utilized to treat semi-inclusive DIS, with emphasis on the structure functions calculable using the spectator model. In Sec. III we present the basic properties of the model and we give the results of our analysis, highlighting what are the broad features that could possibly be observed in experiments.

II. SEMI-INCLUSIVE DIS

The cross section for a semi-inclusive DIS event can be written in terms of the contraction between a lepton and a hadron tensor. For instance in the target rest frame we can make use of the formula
\[
\frac{d\sigma}{dE'd\Omega d^3 P_h} = \frac{\alpha^2}{Q^4} \frac{E'}{E} L_{\mu\nu} W^{\mu\nu}
\]

where \(P_h\) is the momentum of the outgoing hadron, \(Q^2 = -q^2 \geq 0\) is the absolute value of the virtuality of the exchanged photon, \(\alpha = e^2/4\pi\) is the fine structure constant, \(E\) and \(E'\) are the energy of the incident lepton before and after the collision, respectively. \(L_{\mu\nu}\) is the lepton tensor and \(W^{\mu\nu}\) is the hadronic tensor.

Following a purely phenomenological approach, the hadronic tensor can be parameterized using scalar structure functions. A priori, the maximum number of independent structure functions in an arbitrary DIS process is 16. Since we will be interested only in electromagnetic scattering, this number is reduced to 9 by the gauge invariance condition, \(q_{\mu} W^{\mu\nu} = q_{\rho} W^{\mu\nu} = 0\). A convenient set of functions is formed by the spherical basis structure functions (see, e.g., [6]).

In the spherical basis, constraints coming from angular momentum conservation take a simpler form. From now on, we want to consider only leading terms in an expansion over \(1/Q\). In the case of polarized semi-inclusive scattering, helicity conservation considerations allow us to say that five of the structure functions vanish at leading order, leaving only four non-zero structure functions. The complete form of the hadronic tensor at leading order is then

\[
W^{\mu\nu} = -g^{\mu\nu}_{\perp} W_T + i \varepsilon^{\mu\nu}_{\perp} W_{TT} + \left(2 \hat{P}_{h\perp} \hat{P}_{h\nu} + g^{\mu\nu}_{\perp}\right) \frac{W_{TT}}{2} + \hat{P}_{h\perp} \varepsilon^{\nu}_{\perp} \hat{P}_{h\rho} \frac{W_{TT}}{2},
\]

where the curly brackets indicate symmetrization of the indices. For the definitions of the tensor structures appearing in the formula we need to define a normalized time-like and a normalized space-like vector

\[
\hat{t}^\mu = \frac{2x_B}{Q} \left( P^\mu - q^\mu \frac{P \cdot q}{q^2} \right), \quad \hat{q}^\mu = \frac{q^\mu}{Q},
\]

by means of which we can define the structures

\[
g^{\mu\nu}_{\perp} = g^{\mu\nu} + \hat{t}^\mu \hat{q}^\nu - \hat{t}^\mu \hat{t}^\nu,
\]

\[
\varepsilon^{\mu\nu}_{\perp} = \varepsilon^{\mu\nu\alpha\beta} q_{\alpha} \hat{t}_{\beta},
\]

\[
\hat{P}_{h\perp} = \frac{g^{\mu\rho}_{\perp} P_{h\rho}}{|g^{\mu\rho}_{\perp} P_{h\rho}|}.
\]

By calculating the contraction between leptonic and hadronic tensor we can eventually write the following formula for the cross section [6] in the target rest-frame:

\[
\frac{d\sigma}{dE'd\Omega d^3 P_h} = \sigma_M \frac{Q^2}{2|q|^2} \frac{1}{\epsilon} \left\{ W_T + \epsilon \left( W_{TT} \cos 2\phi + W_{TT} \sin 2\phi \right) + \lambda_e \sqrt{1 - \epsilon^2} W_T' \right\},
\]

where \(\lambda_e\) is the helicity of the electron, \(\phi\) is the angle between the scattering plane and the outgoing hadron’s momentum (see Fig. [7]) and where

\[
\sigma_M = \frac{4\alpha^2 E^2}{Q^4} \cos^2 \left( \frac{\theta}{2} \right),
\]

\[
\epsilon^{-1} = 1 + 2 \frac{|q|^2}{Q^2} \tan^2 \left( \frac{\theta}{2} \right),
\]

\(\theta\) being the scattering angle of the electron.
FIG. 1. Sketch of the angles used in the description of the hadronic tensor

FIG. 2. Diagrammatic representation of semi-inclusive DIS
The dominant contribution to the structure functions can be calculated from the cut-diagram shown in Fig. [2] representing the hadronic part of a DIS event.

According to the usual factorization assumption, the diagram is divided into a hard partonic scattering amplitude and two soft parts, $\Phi$ and $\Delta$ in Fig. [2], called correlation functions. The dominant momentum direction in the upper (lower) part is given by the direction of the outgoing (target) hadron momentum, $P_h (P)$. Quark momenta are almost collinear to their parent hadrons allowing for small transverse components. Using Feynman rules we can give an explicit formula describing the diagram of Fig. [2], which represents the hadronic tensor:

$$2MW^{\mu\nu} = \int dk^+ d^2k_T dp^- d^2p_T \delta^{(2)}(p_T + q_T - k_T) \sum_q e^2_q \text{Tr}[\Phi_q \gamma^\mu \Delta_q \gamma^\nu]_{p^+ = x_B p^+, k^- = P_h^- / z}, \quad (9)$$

where $p$ and $k$ are the momenta of the quarks respectively before and after absorbing the photon, and the index $q$ denotes quark flavor.

In this formula we use light-cone components of vectors in an infinite momentum frame of reference where the “+” direction is given by the momentum of the target hadron, $P$, the “−” direction is given by the momentum of the outgoing hadron, $P_h$, and the photon momentum is purely spatial. In this frame of reference the incident photon has a transverse component, $q_T$. In alternative, one can work with frames of reference where the photon does not have transverse components, which are particularly convenient from the experimental point of view. In such frames the outgoing hadron’s momentum acquires a transverse component, which we will denote as $P_{h\perp}$. It can be shown that the relation between these transverse components is [3]:

$$q_T = -\frac{P_{h\perp}}{z}. \quad (10)$$

In Eq. (3) the already mentioned correlation functions appear. They are second-rank Dirac tensors defined as:

$$\Phi_{q(mn)}(p, P, S) = \int \frac{d^4x}{(2\pi)^4} e^{-ipx}\langle P, S | \bar{\psi}(x) \psi(0)|P, S\rangle,$$  

$$\Delta_{q(mn)}(k, P_h, S_h) = \int \frac{d^4x}{(2\pi)^4} e^{ikx}\langle 0 | \bar{\psi}(x) | P_h, S_h\rangle |P_h, S_h\rangle.$$  

If we decompose each correlation function on a basis of 16 Dirac structures, $\Gamma_i$, we get the following result:

$$2MW^{\mu\nu} = \sum_{ij} \frac{\text{Tr}[\Gamma_i \gamma^\mu \Gamma_j \gamma^\nu]}{4} 2z \int d^2k_T d^2p_T \delta^{(2)}(p_T + q_T - k_T) \sum_q e^2_q \Phi_q^{[\Gamma_i]} \Delta_q^{[\Gamma_j]}.$$  

where we defined

$$\Phi_q^{[\Gamma]}(x_B, p_T) = \frac{1}{2} \int dp^- \text{Tr}[\Phi_q \Gamma]\Big|_{p^+ = x_B p^+} \quad \text{(distribution functions)},$$  

$$\Delta_q^{[\Gamma]}(x, k_T) = \frac{1}{2z} \int dk^- \text{Tr}[\Delta_q \Gamma]\Big|_{k^- = P_{h\perp}^- / z} \quad \text{(fragmentation functions)}.$$  

As a last step, the distribution and fragmentation functions are usually divided in several components, named $f_1, g_{1L}, g_{1T}, \ldots$ for what concerns the distribution functions, or $D_1, G_{1L}, G_{1T}, \ldots$ for what concerns the fragmentation functions. We will not pursue the definition of all the possible functions, for which we simply refer to [3]. Note that each function should always carry its flavor index, $q$, although in the rest of this section we are going to skip it.
Using Eq. (23) and comparing it with Eq. (2) we can establish relations connecting structure functions to distribution and fragmentation functions. In the following equations we will use the frame of reference and the angles specified in Fig. 1. We chose to fix the $x$ axis in the direction of $P_{h\perp}$ to simplify the formulae. Note that we do not lose generality because in the hadronic tensor there is no dependence on the angle $\phi$ due to cylindrical symmetry around the $z$ axis.

To be more concise we will denote the convolution integral appearing in the hadronic tensor and the summation over quark flavors with the following notation:

$$
\mathcal{I} \{ \ldots \} = \frac{2z}{M} \int dk_x dk_y dp_x dp_y \delta \left( p_x - \frac{|P_{h\perp}|}{z} - k_x \right) \delta(p_y - k_y) \sum_q e_q^2 \ldots ,
$$

where the specific form of the $\delta$-functions is due to relation (14) and to the particular choice of our $x$ axis.

We are going to divide the structure functions in various contributions arising from particular polarization conditions. Therefore, we are going to label each contribution with two indices, the first one referring to the polarization of the target ($U$ for unpolarized, $L$ for longitudinally polarized, $T$ for transversely polarized) and the second one referring to the polarization of the outgoing hadron.

We will not take into account the cases when both hadrons are polarized.

The resulting form of the structure functions is

$$
W_T(x_B, z, P_{h\perp}) = W_T^{[U]}(x_B, z, P_{h\perp}) + |S_{h\perp}| \sin \beta_h W_T^{[U]}(x_B, z, P_{h\perp}),
$$

$$
W_T^{[U]}(x_B, z, P_{h\perp}) = \mathcal{I} \{ f_1 D_1 \} ,
$$

$$
W_T^{[UT]}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ \frac{k_x}{M_h} f_1 D_{1\perp} \right\} ,
$$

$$
W_{TT}(x_B, z, P_{h\perp}) = |S_{\perp}| \sin \beta_h W_{TT}^{[U]}(x_B, z, P_{h\perp}),
$$

$$
W_{TT}^{[U]}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ \frac{k_x}{M_h} h_{1T} H_1^\perp + \frac{k_y p_y p_x + k_x p_y p_y}{2M^2 M_h} h_{1T}^\perp H_1^\perp \right\} ,
$$

$$
W_{TT}^{[UT]}(x_B, z, P_{h\perp}) = \lambda W_{TT}^{[LU]}(x_B, z, P_{h\perp}) + |S_{h\perp}| \cos \beta_h W_{TT}^{[UT]}(x_B, z, P_{h\perp})
$$

$$
+ \lambda_h W_{TT}^{[UL]}(x_B, z, P_{h\perp}) + |S_{h\perp}| \cos \beta_h W_{TT}^{[UT]}(x_B, z, P_{h\perp}),
$$

$$
W_{TT}^{[LU]}(x_B, z, P_{h\perp}) = \mathcal{I} \{ g_{1L} D_1 \} ,
$$

$$
W_{TT}^{[LT]}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ \frac{p_x}{M} g_{1T} D_1 \right\} ,
$$

$$
W_{TT}^{[LU]}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ f_1 G_{1L} \right\} ,
$$

$$
W_{TT}^{[UT]}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ f_1 \frac{k_x}{M_h} G_{1T} \right\} ,
$$

$$
\overline{W}_{TT}(x_B, z, P_{h\perp}) = \lambda \overline{W}_{TT}^{[LU]}(x_B, z, P_{h\perp}) - |S_{\perp}| \cos \beta \overline{W}_{TT}^{[UT]}(x_B, z, P_{h\perp}),
$$
\[ \mathcal{W}^{[LU]}_{TT}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ \frac{k_x p_x - k_y p_y h_{1L}^\perp}{M M_h} H_1^\perp \right\}, \quad (28) \]

\[ \mathcal{W}^{[TU]}_{TT}(x_B, z, P_{h\perp}) = \mathcal{I} \left\{ \frac{k_x}{M h} h_{1T} H_1^\perp + \frac{k_x p_x p_x - k_y p_y p_x}{M^2 M_h} h_{1T}^\perp H_1^\perp \right\}. \quad (29) \]

Here, \( \lambda (\lambda_h) \) and \( S_\perp (S_{h\perp}) \) denote helicity and transverse spin of the target (outgoing) spin-\( \frac{1}{2} \) hadron.

The distribution functions (small letters) are understood to be functions of the variables \( x_B \) and \( p_T^2 \), while the fragmentation functions (capital letters) are understood to be functions of \( \frac{1}{z} \) and \( k_T^2 \).

The functions \( D_{1T}^\perp \) and \( H_1^\perp \) are time-reversal odd and they cannot be studied in the framework of our model. For this reason we will only be able to calculate the first term of the structure function \( W_T \) and the full structure function \( W_T^{TT} \).

Due to Eq. (10), integrating over the outgoing hadron transverse momentum, \( P_{h\perp} \), corresponds to integrating over \( z^2 q_T \). Performing this integration leads to a deconvolution of the right-hand side of Eq. (13). Consequently, the integrals over \( p_T \) and \( k_T \) can be performed separately for the distribution and fragmentation functions. Therefore, the structure functions integrated over \( P_{h\perp} \) reduce to:

\[ W_T (x_B, z) = \frac{1}{M} 2z f_1(x_B) D_1(\frac{1}{z}), \quad (30) \]

\[ W_T^{TT} (x_B, z) = \frac{\lambda}{M} 2z g_1(x_B) D_1(\frac{1}{z}) + \frac{\lambda_h}{M} 2z f_1(x_B) G_1(\frac{1}{z}), \quad (31) \]

where the new \( p_T \) and \( k_T \)-independent distribution and fragmentation functions are defined as:

\[ f_1(x_B) \equiv \int d^2 p_T f_1(x_B, p_T^2), \quad g_1(x_B) \equiv \int d^2 p_T g_{1L}(x_B, p_T^2), \]

\[ D_1(\frac{1}{z}) \equiv z^2 \int d^2 k_T D_1(\frac{1}{z}, k_T^2), \quad G_1(\frac{1}{z}) \equiv z^2 \int d^2 k_T G_{1L}(\frac{1}{z}, k_T^2). \quad (32) \]

### III. CALCULATION OF STRUCTURE FUNCTIONS

#### A. The spectator model

For a numerical evaluation of the structure functions we will employ the distribution and fragmentation functions as estimated with a spectator model [3]. The basic assumption of the spectator model is that the target hadron can be divided into a quark and an effective spectator state with the required quantum numbers, which is treated to a first approximation as being on-shell with a definite mass. In the case of a baryon target, this second particle is a diquark.

The same idea applies to the hadronization process: the quark fragments into a jet, from which one hadron is eventually detected; the remnants of the jet are treated effectively as an on-shell spectator state. If the detected hadron is a baryon, the second particle is an anti-diquark.

The vertex coupling the baryon to quark and diquark includes a form factor preventing the quark from being far off-shell. The large \( p^2 \)-behavior of the form factor is controlled by a parameter \( \Lambda \).

We quote the analytic form of the distribution and fragmentation function we are going to use for numerical evaluation of the structure functions as obtained in [4]. The diquark’s spin in the simplest approach can be either 0 (scalar diquark with mass \( M_0 \)) or 1 (axial vector diquark with mass \( M_a \)). For both cases the functions can be cast in the same analytic form where only some parameters take
between the two cases. The functions we consider are:

\begin{align}
   f^i_1(x_B, p_T^2) &= \frac{n_i^2(1-x_B)^3}{16\pi^3} \frac{(m + x_B M)^2 + p_T^2}{(p_T^2 + l_i^2(x))^4}, \\
   g_{1L}^i(x_B, p_T^2) &= a_i \frac{n_i^2(1-x_B)^3}{16\pi^3} \frac{(m + x_B M)^2 - p_T^2}{(p_T^2 + l_i^2(x))^4}, \\
   g_{1T}^i(x_B, p_T^2) &= a_i \frac{n_i^2(1-x_B)^3}{16\pi^3} \frac{2M(m + x_B M)}{(p_T^2 + l_i^2(x))^4}, \\
   D_i^i(\frac{1}{z}, k_T^2) &= \frac{N_i^2(1-z)^3}{16\pi^3 z^4} \frac{(m + \frac{1}{z} M_h)^2 + k_T^2}{(k_T^2 + L_i^2(z))^4}, \\
   G_{1L}^i(\frac{1}{z}, k_T^2) &= a_i \frac{N_i^2(1-z)^3}{16\pi^3 z^4} \frac{(m + \frac{1}{z} M_h)^2 - k_T^2}{(k_T^2 + L_i^2(z))^4}, \\
   G_{1T}^i(\frac{1}{z}, k_T^2) &= a_i \frac{N_i^2(1-z)^3}{16\pi^3 z^4} \frac{2M_h(m + \frac{1}{z} M_h)}{(k_T^2 + L_i^2(z))^4},
\end{align}

with the spin factors \(a_s = 1\) and \(a_a = -\frac{1}{3}\), and where we made use of the newly defined functions:

\begin{align}
   L_i^2(x_B) &= \Lambda^2(1-x_B) + x_B M_i^2 - x_B (1-x_B) M^2, \\
   L_i^2(z) &= \Lambda^2(1-\frac{1}{z}) + \frac{1}{z} M_i^2 - \frac{1}{z}(1-\frac{1}{z}) M_h^2.
\end{align}

The values of the parameters of the model have been determined to be

\begin{align}
   \Lambda &= 0.5 \text{ GeV}, \\
   M_s &= 0.6 \text{ GeV}, \\
   M_a &= 0.8 \text{ GeV}, \\
   m &= 0.36 \text{ GeV}.
\end{align}

The functions depend only weakly on the chosen value of the quark mass \(m\). The normalization factors \(n_i\) and \(N_i\) are fixed by the conditions

\begin{align}
   \int dx_B \, d^2p_T \, f^i_1(x_B, p_T^2) &= 1, \\
   \int dz \, d^2k_T \, z \left(z^2 D_i^i(\frac{1}{z}, k_T^2)\right) &= 1.
\end{align}

Note that for the fragmentation function the normalization condition is put on the first moment.

It is noteworthy to observe that the model intrinsically describes the dependence of distribution and fragmentation functions on partonic transverse momentum. Moreover, this dependence is significantly different from the frequently used Gaussian dependence.

We gave the distribution and fragmentation functions for scalar and axial-vector diquarks. We must now address the problem of defining the hadron state in terms of the quark-diquark content. From a group theory analysis, for a proton, a neutron and a \(\Lambda\) particle the results are [4]:

\begin{align}
   |p\rangle &= \frac{1}{\sqrt{2}} |u, S\rangle + \frac{1}{\sqrt{6}} |u, A\rangle - \frac{1}{\sqrt{3}} |d, A\rangle, \\
   |n\rangle &= \frac{1}{\sqrt{2}} |d, S\rangle - \frac{1}{\sqrt{6}} |d, A\rangle + \frac{1}{\sqrt{3}} |u, A\rangle, \\
   |\Lambda\rangle &= \frac{1}{\sqrt{12}} |u, S\rangle - \frac{1}{\sqrt{12}} |d, S\rangle - \frac{2}{\sqrt{12}} |s, S\rangle + \frac{1}{\sqrt{4}} |u, A\rangle - \frac{1}{\sqrt{4}} |d, A\rangle.
\end{align}
Using these results, the probability of finding an up, down or strange quark in one of these hadrons is related to the probability of finding a scalar or axial-vector diquark in the following way:

\[
\begin{align*}
    f_{p \to u}^{\nu} &= \frac{3}{2} f_{1}^s + \frac{1}{2} f_{1}^a, & f_{p \to d}^{\nu} &= f_{1}^s, \\
    f_{n \to u}^{\nu} &= f_{1}^a, & f_{n \to d}^{\nu} &= \frac{3}{2} f_{1}^s + \frac{1}{2} f_{1}^a, \\
    f_{\Lambda \to u}^{\nu} &= \frac{1}{4} f_{1}^s + \frac{3}{4} f_{1}^a, & f_{\Lambda \to d}^{\nu} &= \frac{1}{4} f_{1}^s + \frac{3}{4} f_{1}^a, & f_{1}^{\Lambda \to s} &= f_{1}^a.
\end{align*}
\]  

(44)

Overall normalizations ensure the correct number sum rules for valence quarks in the baryons. Analogous formulae hold for all other distribution functions and for the fragmentation functions as well.

Once we have computed the distribution and fragmentation functions for a scalar and axial-vector diquark, we can eventually calculate the argument of the convolutions occurring in the structure functions for a given process. At this stage, the (charge squared weighted) sum over quark flavors is rewritten in a weighted sum over the different diquark species:

\[
\sum_q e_q^2 f_q^i D_q^i = \sum_{i,j=s,a} c_{ij} f_{1}^i D_{j}^i,
\]  

(45)

where the coefficients depend on the type of hadrons involved.

For instance, for the following processes:

- \( e p \to e' \Lambda X \)

\[
\frac{4}{9} f_{1}^{p \to u} D_{1}^{u \to \Lambda} + \frac{1}{9} f_{1}^{p \to d} D_{1}^{d \to \Lambda} = \frac{1}{6} f_{1}^s D_{1}^s + \frac{1}{2} f_{1}^s D_{1}^a + \frac{1}{12} f_{1}^a D_{1}^s + \frac{1}{4} f_{1}^a D_{1}^a;
\]  

(46)

- \( e p \to e' p' X \)

\[
\frac{4}{9} f_{1}^{p \to u} D_{1}^{u \to p} + \frac{1}{9} f_{1}^{p \to d} D_{1}^{d \to p} = f_{1}^s D_{1}^s + \frac{1}{3} f_{1}^s D_{1}^a + \frac{1}{3} f_{1}^a D_{1}^s + \frac{2}{9} f_{1}^a D_{1}^a;
\]  

(47)

- \( e n \to e' \Lambda X \)

\[
\frac{4}{9} f_{1}^{n \to u} D_{1}^{u \to \Lambda} + \frac{1}{9} f_{1}^{n \to d} D_{1}^{d \to \Lambda} = \frac{1}{24} f_{1}^s D_{1}^s + \frac{1}{8} f_{1}^s D_{1}^a + \frac{1}{8} f_{1}^a D_{1}^s + \frac{3}{8} f_{1}^a D_{1}^a;
\]  

(48)

- \( e n \to e' p X \)

\[
\frac{4}{9} f_{1}^{n \to u} D_{1}^{u \to p} + \frac{1}{9} f_{1}^{n \to d} D_{1}^{d \to p} = \frac{1}{6} f_{1}^s D_{1}^s + \frac{2}{3} f_{1}^s D_{1}^a + \frac{5}{18} f_{1}^a D_{1}^a.
\]  

(49)

Analogous formulae apply to other combinations of distribution and fragmentation functions.

In the following section we will concentrate only on the first process. However, using appropriate coefficients \( c_{ij} \) and appropriate hadron masses one can carry out the calculations for any baryon-to-baryon process.
FIG. 3. Dependence of the structure function $W_T^{[UU]}$ on $x_B$ and $z$ at $P_{h\perp}=0$.

B. Numerical results for structure functions in $e p \rightarrow e' \Lambda X$

In this section we present numerical results for structure functions of the process $e p \rightarrow e' \Lambda X$ obtained using the distribution and fragmentation functions from the spectator model. We concentrate on $\Lambda$ production, since it is possible to determine its polarization from the kinematics of its decay. We will consider separately different experimental situations with or without polarization of the target and of the produced $\Lambda$. In this way the various terms in Eq. (17) and Eq. (22) can be accessed.

1 - Unpolarized proton target and unpolarized produced $\Lambda$. We performed the calculation of the structure function $W_T^{[UU]}$ of Eq. (18) using $f_1$ from Eq. (33) and $D_1$ from Eq. (36), with the coefficients $c_{ij}$ as specified in Eq. (46). After integrating over $k_x$ and $k_y$ by using the $\delta$-function we obtain

$$W_T^{[UU]}(x_B, z, P_{h\perp}) = \sum_{i,j=s,a} c_{ij} \frac{n_i^2 N_f^2}{2M(2\pi)^2} (1 - x_B)^3 \left(\frac{1 - z}{z}\right)^3 \int dp_x dp_y \times \left[\frac{(m + x_B M)^2 + p_x^2 + p_y^2}{(p_x^2 + p_y^2 + L_i^2(x))^4} \right] \left[\frac{(m + \frac{1}{z} M_h)^2}{(p_x - \frac{|P_{h\perp}|}{z})^2 + p_y^2 + L_j^2(z)}\right]^2. \quad (50)$$

The remaining integration has been carried out making use of an adaptive multi-dimensional integration method. As we remarked before, integrating out $P_{h\perp}$ leads to a deconvolution and, consequently, the transverse momentum integration can be performed separately for the distribution and fragmentation functions as shown in Eq. (30). With the form of the functions given by the spectator model the integrations can be carried out analytically [3]. Comparison of those analytical results with the outcome of a numerical integration has been used as a check of consistency.

The results are displayed in the plots. Fig. 3 shows the structure function $W_T^{[UU]}$ at $P_{h\perp}=0$. Fig. 4 shows the contour-plot of the same function at three different values of $P_{h\perp}$. An interesting feature is that when $P_{h\perp}$ increases, the position of the peak slowly moves to lower values of $z$ while there is no change in the $x$ position of the peak. In other words, a hadron produced with a higher transverse momentum is more likely to carry a lower fraction of the longitudinal momentum of the original quark. We remark that this behavior is due to the kinematical conditions imposed by momentum conservation.
FIG. 4. Contour-plot of the structure function \( W_{T}^{[UU]} \) for different values of \( P_{h\perp} \) (GeV). Numbers inside the plot area denote the height of maxima. Spacing between isometric lines corresponds to 10% of maximum height.

(a) (b)

FIG. 5. Dependence of the structure function \( W_{T}^{[UU]} \) on the outgoing hadron transverse momentum, \( P_{h\perp} \) (measured in GeV) and: (a) the fractional momentum \( x_{B} \), (b) the fractional momentum \( z \).

In Fig. 5 we show the results obtained by integrating the structure function over \( z \) or \( x_{B} \), respectively.

Finally, we can integrate over both \( z \) and \( x_{B} \) at the same time, thereby obtaining the dependence of the structure function \( W_{T}^{[UU]} \) on \( P_{h\perp} \) alone (Fig. 6). This dependence is connected with the distribution of transverse momentum of quarks inside the hadron. In principle, comparison with experimental data could be used to discriminate between different assumptions on this distribution.

2 - Longitudinally polarized proton target and unpolarized produced \( \Lambda \). In this case, we need to calculate the structure function \( W'_{TT}^{[LU]} \) of Eq. (23). Using Eq. (34) and Eq. (36) and integrating over \( k_{x} \) and \( k_{y} \) using the \( \delta \)-functions, we obtain the formula

\[
W'_{TT}^{[LU]}(x_{B}, z, P_{h\perp}) = \sum_{i,j=s,a} c_{ij} a_{i} \frac{n_{i}^{2} N_{j}^{2}}{2 M_{2}(2\pi)^{3}} (1 - x_{B})^{3} \left( \frac{1 - z}{z} \right)^{3} \int dp_{x} dp_{y} \\
\times \frac{(m + x_{B} M) - p_{x}^{2} - p_{y}^{2}}{[p_{x}^{2} + p_{y}^{2} + L_{j}^{2}(x)]^{4}} \left( m + \frac{1}{z} M_{h} \right)^{2} \left( p_{x} - \frac{P_{h\perp}}{z} \right)^{2} + p_{y}^{2} \\
\times \left( \left( p_{x} - \frac{P_{h\perp}}{z} \right)^{2} + p_{y}^{2} + L_{j}^{2}(z) \right)^{4}. \quad (51)
\]
Fig. 6. Dependence of the structure function \( W_{TT}^{|UU|} \) on the outgoing hadron transverse momentum, \( P_{h\perp} \) (GeV).

Fig. 6 shows the structure function \( W_{TT}^{|LU|} \) at \( P_{h\perp} = 0 \). Fig. 8 shows the contour-plot of the same function at three different values of \( P_{h\perp} \). As in the case of \( W_{TT}^{|UU|} \), for increasing \( P_{h\perp} \) the position of the peak moves to lower values of \( z \).

Integration over \( z \) or \( x_B \) produces a behavior similar to the one shown in Fig. 5.

Integrating over both \( z \) and \( x_B \) we obtain the dependence of the structure function \( W_{TT}^{|LU|} \) on \( P_{h\perp} \) alone (Fig. 9).

3 – Transversely polarized proton target and unpolarized produced \( \Lambda \).

Substituting the results coming from Eq. (35) and Eq. (36) in Eq. (24) and integrating over \( k_x \) and \( k_y \) we obtain

\[
W_{TT}^{|LU|}(x_B, z, P_{h\perp}) = \sum_{i,j=s,a} c_{ij} a_i \frac{n_i^2 N_i^2}{2M(2\pi)^3} (1 - x_B)^3 \left( \frac{1 - z}{z} \right)^3 \int dp_x dp_y \\
\times \frac{2p_x (m + x_B M)}{p_x^2 + p_y^2 + L_i^2(x)} \left[ \frac{m + \frac{1}{z} M_h}{2} \right] \left( p_x - \frac{P_{h\perp}}{z} \right)^2 + p_y^2 + p_y^2 + L_j^2(z) \right]^{\frac{1}{2}}. \tag{52}
\]

Fig. 10 shows the structure function \( W_{TT}^{|LU|} \) at \( P_{h\perp} = 0.4 \text{ GeV} \). Fig. 11 shows the contour-plot of the same function at three different values of \( P_{h\perp} \). Again, as \( P_{h\perp} \) increases the position of the peak moves to lower values of \( z \).

Integrating over both \( z \) and \( x_B \) we obtain the dependence of the structure function \( W_{TT}^{|LU|} \) on \( P_{h\perp} \) alone (Fig. 12).

4 – Unpolarized proton target and longitudinally polarized produced \( \Lambda \).

Substituting the results coming from Eq. (33) and Eq. (34) in Eq. (25) and integrating over \( k_x \) and \( k_y \) we obtain

\[
W_{TT}^{|UL|}(x_B, z, P_{h\perp}) = \sum_{i,j=s,a} c_{ij} a_j \frac{n_i^2 N_i^2}{2M(2\pi)^3} (1 - x_B)^3 \left( \frac{1 - z}{z} \right)^3 \int dp_x dp_y \\
\times \frac{(m + x_B M)^2 + p_x^2 + p_y^2}{p_x^2 + p_y^2 + L_i^2(x)} \left[ \frac{m + \frac{1}{z} M_h}{2} \right] \left( p_x - \frac{P_{h\perp}}{z} \right)^2 - p_y^2 + p_y^2 + L_j^2(z) \right]^{\frac{1}{2}}. \tag{53}
\]
FIG. 7. Dependence of the structure function $W'_{T T}^{[L,U]}$ on $x_B$ and $z$ at $P_{h\perp} = 0$.

FIG. 8. Contour-plot of the structure function $W'_{T T}^{[L,U]}$ for different values of $P_{h\perp}$ (GeV). Numbers inside the plot area denote the height of maxima. Spacing between isometric lines corresponds to 10% of maximum height.
FIG. 9. Dependence of the structure function $W'_{TT}^{[LU]}$ on the outgoing hadron transverse momentum, $P_{h\perp}$ (GeV).

FIG. 10. Dependence of the structure function $W'_{TT}^{[TU]}$ on $x_B$ and $z$ at $P_{h\perp} = 0.4$ GeV.
FIG. 11. Contour-plot of the structure function $W'_{TT}$ for different values of $P_{h\perp}$ (GeV). Numbers inside the plot area denote the height of maxima. Spacing between isometric lines corresponds to 10% of maximum height.

FIG. 12. Dependence of the structure function $W'_{TT}$ on the outgoing hadron transverse momentum, $P_{h\perp}$ (GeV).
FIG. 13. Dependence of the structure function $W'_{TT}$ on $x_B$ and $z$ at two different values of $P_{h\perp}$.

Fig. 13 shows the structure function $W'_{TT}$ at $P_{h\perp} = 0$ and at $P_{h\perp} = 0.5$ GeV. In this case, the contributions containing the negative $a_s$ factor play a larger role than in the previous cases. For this reason, the significance of the contour plots is reduced and we preferred to show 3-D plots of the structure function.

Integrating over both $z$ and $x_B$ we obtain the dependence of the structure function $W'_{TT}$ on $P_{h\perp}$ alone (Fig. 14).

5 – Unpolarized proton target and transversely polarized produced $\Lambda$. Substituting the results coming from Eq. (33) and Eq. (35) in the fourth term of Eq. (22) and integrating over $k_x$ and $k_y$ we obtain

$$W'_{TT}(x_B, z, P_{h\perp}) = \sum_{i,j=s,a} C_{ij}^{2M(2\pi)^6} \left(1 - x_B\right)^3 \left(\frac{1 - z}{z}\right) \int dp_x dp_y \frac{p_x^2 + p_y^2 + (m + x_B M)^2}{(p_x^2 + p_y^2 + l_i^2(x))^4} \frac{2 \left(p_x - \frac{|P_{h\perp}|}{z}\right) \left(m + \frac{1}{z} M_H\right)}{\left(p_x - \frac{|P_{h\perp}|}{z}\right)^2 + p_y^2 + L_j^2(z)}.$$ (54)

Fig. 15 shows the structure function $W'_{TT}$ (we plot $-W'_{TT}$ for display convenience) at $P_{h\perp} = 0.4$ GeV and $P_{h\perp} = 0.8$ GeV.

Integrating over both $z$ and $x_B$ we obtain the dependence of the structure function $W'_{TT}$ on $P_{h\perp}$ alone (Fig. 16).

IV. CONCLUSIONS

In this paper the structure functions appearing in the cross section of polarized one-particle inclusive deep-inelastic scattering have been expressed in terms of distribution and fragmentation functions. Suitable kinematic conditions allow to extract selected structure functions and thus to access particular combinations of distribution and fragmentation functions.

We made use of a simple spectator model to calculate the relevant structure functions involved in the cross section. Our analysis can be applied to any process involving a baryonic spin-$\frac{1}{2}$ target and an outgoing spin-$\frac{1}{2}$ baryon. We chose to focus our attention on the process $e p \rightarrow e' \Lambda X$. Using our
FIG. 14. Dependence of the structure function $W'_{TT}$ on the outgoing hadron transverse momentum, $P_{h\perp}$ (GeV).

$P_{h\perp} = 0.4 \text{ GeV}$

FIG. 15. Dependence of the structure function $-W'_{TT}$ on $x_B$ and $z$ at two different values of $P_{h\perp}$.

$P_{h\perp} = 0.7 \text{ GeV}$
results it is possible to estimate cross-sections for the cases when proton and $\Lambda$ are both unpolarized or when one of the two is polarized.

An important feature of the analysis we presented is that we calculated the dependence of the cross-sections on the transverse momentum of the outgoing hadron, $P_{h\perp}$. The measurement of this variable gives access to two new contributions to the structure functions. These contributions have never been observed so far, because they vanish if the cross-section is integrated over $P_{h\perp}$. Furthermore, the dependence of the cross-section on $P_{h\perp}$ indirectly tests the distribution of partonic transverse momentum inside the hadron. This distribution is largely unknown at the moment.

The spectator model allows to study $P_{h\perp}$-dependent cross-sections because it produces a well-defined, analytical form of transverse momentum distributions. Since the model qualitatively agrees with totally inclusive measurements, we expect it to give good hints on the $P_{h\perp}$ dependence, as well.

In summary, we are confident that the presented estimate can reproduce the broad features of the structure functions observable in semi-inclusive deep inelastic scattering.
