DENSITIES IN FREE GROUPS AND $\mathbb{Z}^k$, VISIBLE POINTS AND TEST ELEMENTS

ILYA KAPOVICH, IGOR RIVIN, PAUL SCHUPP, AND VLADIMIR SHPILRAIN

Abstract. In this article we relate two different densities. Let $F_k$ be the free group of finite rank $k \geq 2$ and let $\alpha$ be the abelianization map from $F_k$ onto $\mathbb{Z}^k$. We prove that if $S \subseteq \mathbb{Z}^k$ is invariant under the natural action of $SL(k, \mathbb{Z})$ then the asymptotic density of $S$ in $\mathbb{Z}^k$ and the annular density of its full preimage $\alpha^{-1}(S)$ in $F_k$ are equal. This implies, in particular, that for every integer $t \geq 1$, the annular density of the set of elements in $F_k$ that map to $t$-th powers of primitive elements in $\mathbb{Z}^k$ is equal to to $\frac{1}{t^k \zeta(k)}$, where $\zeta$ is the Riemann zeta-function.

An element $g$ of a group $G$ is called a test element if every endomorphism of $G$ which fixes $g$ is an automorphism of $G$. As an application of the result above we prove that the annular density of the set of all test elements in the free group $F(a, b)$ of rank two is $1 - \frac{6}{\pi^2}$. Equivalently, this shows that the union of all proper retracts in $F(a, b)$ has annular density $\frac{6}{\pi^2}$. Thus being a test element in $F(a, b)$ is an "intermediate property" in the sense that the probability of being a test element is strictly between 0 and 1.

1. Introduction

The idea of genericity and generic-case behavior in finitely presented groups was introduced by Gromov [14, 15] and is currently the subject of much research. (See, for example [1, 2, 3, 4, 6, 7, 8, 16, 19, 20, 21, 22, 23, 30, 31, 46].) Looking at the properties of random groups led Gromov [16] to a probabilistic proof that there exists a finitely presented group that is not uniformly embeddable in a Hilbert space. It also turns out that random group-theoretic objects exhibit various kinds of algebraic rigidity properties. In particular, Kapovich, Schupp and Shpilrain [21] proved that a random cyclically reduced element of a free group $F = F(A)$ is of minimal length in its $Aut(F)$-orbit and that such an element has a trivial stabilizer in $Out(F)$. Moreover, it turns out [21] that random one-relator groups satisfy a strong Mostow-type rigidity. Specifically, two random one-relator groups $G_r = \langle a_1, \ldots, a_k | r \rangle$ and $G_s = \langle a_1, \ldots, a_k | s \rangle$ are isomorphic if and only if their Cayley graphs on the given set of generators $\{a_1, \ldots, a_k\}$ are isomorphic as labelled graphs where the graph isomorphism is only allowed to permute the label set $\{a_1, \ldots, a_k\}^{\pm 1}$.

The most straightforward definition of “genericity” is based on the notion of “asymptotic density”.

Definition 1.1 (Asymptotic density). Suppose that $T$ is a countable set and that $\ell : T \to \mathbb{N}$ is a function (referred to as length) such that for every $n \in \mathbb{N}$ the set

\[ \ell^{-1}(\{1, \ldots, n\}) \]

is finite.

2000 Mathematics Subject Classification. Primary 20P05, Secondary 11M, 20F, 37A, 60B, 60F.
\[ \{ x \in T : \ell(x) \leq n \} \text{ is finite. If } X \subseteq T \text{ and } n \geq 0, \text{ we denote } \rho_\ell(n, X) := \# \{ x \in X : \ell(x) \leq n \} \text{ and } \gamma_\ell(n, S) = \# \{ x \in X : \ell(x) = n \} . \]

Let \( S \subseteq T \). The asymptotic density of \( S \) in \( T \) is

\[
\overline{\sigma}_{T,\ell}(S) := \limsup_{n \to \infty} \frac{\# \{ x \in S : \ell(x) \leq n \}}{\# \{ x \in T : \ell(x) \leq n \}} = \limsup_{n \to \infty} \frac{\rho_\ell(n, S)}{\rho_\ell(n, T)},
\]

where we treat a fraction \( \frac{0}{0} \) if it occurs, as 0.

If the actual limit exists, we denote it by \( \rho_{T,\ell}(S) \) and call this limit the strict asymptotic density of \( S \) in \( T \). We say that \( S \) is generic in \( T \) with respect to \( \ell \) if \( \rho_{T,\ell}(S) = 1 \) and that \( S \) is negligible in \( T \) if \( \rho_{T,\ell}(S) = 0 \).

If \( S \) is \( T \)-generic then the probability that a uniformly chosen element of \( T \) of length at most \( n \) belongs to \( S \) tends to 1 as \( n \) tends to infinity.

It turns out that a different density, recording the proportions of a set in two successive spheres, is sometimes more suitable for subsets of a free group.

**Definition 1.2** (Annular Density). Let \( T, S, \ell \) be as in Definition 1.1. The annular density of \( S \) in \( T \) with respect to \( \ell \) is:

\[
\overline{\sigma}_{T,\ell}(S) := \limsup_{n \to \infty} \frac{1}{2} \left( \frac{\# \{ x \in S : \ell(x) = n - 1 \}}{\# \{ x \in T : \ell(x) = n - 1 \}} + \frac{\# \{ x \in S : \ell(x) = n \}}{\# \{ x \in T : \ell(x) = n \}} \right) = \limsup_{n \to \infty} \frac{1}{2} \left( \frac{\gamma_\ell(n-1, S)}{\gamma_\ell(n-1, T)} + \frac{\gamma_\ell(n, S)}{\gamma_\ell(n, T)} \right),
\]

where we treat a fraction \( \frac{0}{0} \) if it occurs, as 0. Again, if the actual limit exists, we denote this limit by \( \sigma_{T,\ell}(S) \) and call it the strict annular density of \( S \) in \( T \) with respect to \( \ell \).

**Convention 1.3.** Throughout this paper \( F = F(A) \) will be a free group of rank \( k \geq 2 \) with a fixed finite basis \( A = \{ a_1, \ldots, a_k \} \). If \( w \in F \) then \( |w|_A \) denotes the freely reduced length of \( w \) with respect to the basis \( A \). In discussing the density (asymptotic or annular) of subsets of \( F \) using the notation above, we will assume that the ambient set is \( T = F \) and that the length function \( \ell(w) = |w|_A \). If \( S \subseteq F \) we denote its asymptotic and annular densities by \( \overline{\sigma}_A(S) \) and \( \overline{\sigma}_A(S) \) respectively, and if the strict asymptotic density or the strict annular density exist we denote them by \( \rho_A(S) \) and \( \sigma_A(S) \) respectively. Also, we denote \( \gamma_A(S) := \gamma_\ell(S) \) and \( \rho_A(n, S) := \rho_\ell(n, S) \) in this case.

For subsets of \( \mathbb{Z}^k \) a length function \( \ell : \mathbb{Z}^k \to \mathbb{R} \) will usually be the restriction to \( \mathbb{Z}^k \) of \( \| \cdot \|_p \) norm from \( \mathbb{R}^k \) for some \( 1 \leq p \leq \infty \). In this case for \( S \subseteq \mathbb{Z}^k \) we denote the corresponding asymptotic density of \( S \) in \( T = \mathbb{Z}^k \) by \( \overline{\sigma}_p(S) \) and if the strict asymptotic density exists, we denote it by \( \rho_p(S) \).

It is not hard to see that if for a subset \( S \subseteq F \) the strict asymptotic density \( \rho_A(S) \) exists then the strict annular density \( \sigma_A(S) \) also exists and in fact \( \sigma_A(S) = \rho_A(S) \). Namely, since the sizes of both the balls and the spheres in \( F(A) \) grow as constant multiples of \( (2k-1)^n \), if the strict asymptotic density \( \rho_A(S) \) exists, then the limit \( \lim_{n \to \infty} \frac{\gamma_A(n, S)}{\gamma_A(n, F)} \) exists and is equal to \( \rho_A(S) \). Then the definition of \( \sigma_A(S) \) implies that the strict annular density \( \sigma_A(S) \) exists and is also equal to \( \rho_A(S) \). However, as Example below shows, it is possible that \( \sigma_A(S) \) exists while \( \rho_A(S) \) does not. Thus there are reasonable situations where the parity of the radius of a sphere or a ball affects the outcome when measuring the relative size of a subset of a free group, and annular density turns out to be a more suitable and relevant
quantity. This is the case when we consider a subset of \( \mathbb{Z}^k \) and the full preimage of this subset in \( F \) under the abelianization map. Moreover, annular density and its “close relatives” also make sense from the computational perspective. A typical experiment for generating a “random” element in a ball \( B(n) \) of radius \( n \) in \( F(A) \) might proceed as follows. First choose a uniformly random integer \( m \in [0,n] \) and then choose a uniformly random element \( x \) from the \( m \)-sphere in \( F(A) \) via a simple non-backtracking random walk of length \( m \). It is easy to see that this experiment, while very natural, does not correspond to the uniform distribution on \( B(n) \). For example, if \( F \) has rank \( k = 2 \), then for the uniform distribution on \( B(n) \) the probability that the element \( x \) has length \( n \) is approximately \( 2^{-3} \) for large \( n \) while in our experiment described above this probability is \( 1/(n+1) \). In fact if \( w \in B(n) \) then the probability of choosing the element \( w \) in the above experiment is \( 1/(n+1)^{\#S(m)} \) where \( m \) is the freely reduced length of \( w \) and where \( S(m) \) is the sphere of radius \( m \) in \( F \). Thus if \( X \subseteq F \) then the probability of choosing an element of \( X \) in the above experiment is

\[
\frac{1}{n+1} \sum_{m=0}^{n} \frac{\#(X \cap S(m))}{\#S(m)}.
\]

If in our experiment we choose an element of \( S(n-1) \cup S(n) \) by first randomly and uniformly choosing \( m \in \{n-1,n\} \) and then choosing a uniformly random element of \( S(m) \), then for a subset \( X \) of \( F \) the probability of picking an element of \( X \) is

\[
\frac{1}{2} \left( \frac{\#(X \cap S(n-1))}{\#S(n-1)} + \frac{\#(X \cap S(n))}{\#S(n)} \right),
\]

and the formulas from the definition of annular density appear.

For most of the cases where one can actually compute the asymptotic density of the set of elements in a free group having some natural algebraic property, this set turns out to be either generic or negligible. (Of course, a subset is negligible if and only if its complement is generic.) The following subsets are known to be negligible in a free group \( F = F(A) \) of rank \( k \geq 2 \), both in the sense of asymptotic and annular densities: the set of all proper powers \([1]\), a finite union of conjugacy classes, a subgroup of infinite index \([44]\), a finite union of automorphic orbits (e.g. the set of all primitive elements) \([13,21]\), the set of all elements whose cyclically reduced forms are not automorphically minimal \([21]\), the union of all proper free factors of \( F \) (this follows from results of \([41]\) and \([5,4,21]\)). Examples of generic sets, again in the sense of both the asymptotic and the annular densities, include: the set of all words whose symmetrizations satisfy the \( C'(1/6) \) small cancellation condition \([1]\), the set of words with nontrivial images in the abelianization of \( F(A) \) \([44]\) and the set of elements of \( F(A) \) with cyclic stabilizers in \( Aut(F(A)) \) \([21]\). It is therefore interesting to find examples of natural properties of elements of free groups which are “intermediate” in the sense that they have density different from either 0 or 1.

In this article we show that being a test element in the free group of rank two is such an example.

**Convention 1.4 (The abelianization map).** Recall that \( F \) is a free group of rank \( k \geq 2 \) with free basis \( A = \{a_1,\ldots,a_k\} \). We identify \( \mathbb{Z}^k \) with the abelianization of \( F \) where the abelianization homomorphism \( \alpha : F \to \mathbb{Z}^k \) is given by \( a_i \mapsto e_i \), \( i = 1,\ldots,k \). We also denote \( \alpha(w) \) by \( \overline{w} \).
It is easy to construct an example of a subset \( H \) of \( F \) such that the annular density of \( H \) in \( F \) and the asymptotic density of \( \alpha(H) \) in \( \mathbb{Z}^k \) are different. For instance, let \( F = F(a,b) \) and consider the subgroup \( H = \langle a,b|a,b \rangle \leq F \). Then \( H \) has infinite index in \( F \) and hence has both asymptotic and annular density 0 in \( F \). On the other hand, \( \alpha(H) = \alpha(F) = \mathbb{Z}^2 \) has asymptotic density 1 in \( \mathbb{Z}^k \) with respect to any length function on \( \mathbb{Z}^2 \).

**Example 1.5.** Let \( F = F(a,b) \), where \( A = \{a,b\} \), be free of rank two. Let \( \alpha : F \to \mathbb{Z}^2 \) be the abelianization map. Note that for any \( w \in F \) the length \( |w|_A \) and \( ||\alpha(w)||_1 \) have the same parity, since \( ||\alpha(w)||_1 = |w_a| + |w_b| \), where \( w_a, w_b \) are the exponent sums on \( a \) and \( b \) in \( w \). Let \( S = \{ z \in \mathbb{Z}^2 : ||z||_1 \text{ is even} \} \) and let \( \tilde{S} := \alpha^{-1}(S) \subseteq F \). Then \( \tilde{S} = \{ w \in F : |w|_A \text{ is even} \} \). It is not hard to see that the strict asymptotic density of \( S \) in \( \mathbb{Z}^2 \), with respect to \( ||.||_p \) for any \( 1 \leq p \leq \infty \), exists and is equal to 1/2.

Since \( \tilde{S} \) is exactly the union of all spheres of even radii in \( F \), and the ratio of the sizes of spheres of radius \( n \) and \( n-1 \) is equal to 3, it follows that the limits \( \lim_{n \to \infty} \frac{\#\{w \in \tilde{S} : |w|_A = n\}}{\#\{w \in F : |w| = n\}} \) and \( \lim_{n \to \infty} \frac{\#\{w \in \tilde{S} : |w|_A \leq n\}}{\#\{w \in F : |w| \leq n\}} \) do not exist. However, it is easy to see that for every \( n \geq 1 \)

\[
\frac{\#\{w \in \tilde{S} : |w|_A = n - 1\}}{\#\{w \in F : |w|_A = n - 1\}} + \frac{\#\{w \in \tilde{S} : |w|_A = n\}}{\#\{w \in F : |w|_A = n\}} = 1,
\]

and therefore \( \sigma_A(\tilde{S}) = \frac{1}{2} \). Thus although the strict asymptotic density of \( \tilde{S} \subseteq F \) does not exist, the strict annular density does exist and is equal to the strict asymptotic density of \( S \subseteq \mathbb{Z}^2 \). More examples of a similar nature are discussed in Remark 1.8 of [33].

Example 1.5 demonstrates why the notion of annular density is suitable for working with subsets of free groups, while asymptotic density is more suitable for subsets of free abelian groups. Geometrically, this difference comes from the fact that free abelian groups are amenable with balls forming a Folner sequence, while free groups are non-amenable.

Although the counting occurs in very different places, it is interesting to ask how the asymptotic density of a subset \( S \subseteq \mathbb{Z}^k \), with respect to some natural length function, and the annular density of its full preimage \( \alpha^{-1}(S) \) in \( F \) are related. We shall see that there is a reasonable assumption about the set \( S \) which guarantees that the two densities are actually equal.

To do this we need to understand the image of the uniform distribution on the sphere of radius \( n \) in \( F \) under the abelianization map \( \alpha \). There is an explicit formula for the size of the preimage of an element, and there is also a Central Limit Theorem saying that, when appropriately normalized, the distribution converges to a normal distribution. The methods of [33] also give a Local Limit Theorem showing that, when working with width-two spherical shells in a free group, the densities of the image distributions in \( \mathbb{Z}^k \) converge to a normal density. Such a result was later also shown (by rather different methods, and in greater generality) by Richard Sharp in [33]. Recently Petridis and Risager [33] obtained a similar Local Limit Theorem for counting conjugacy classes rather than elements of \( F \). On the face of it, studying the annular density of the set \( \alpha^{-1}(S) \) in \( F \) presents new challenges. The central limit theorem by itself seems too crude a tool and a priori it would appear that one would need very sharp error bounds in the local limit theorem. Nevertheless,
we produce a short argument solving this problem where one of the key ingredients is the ergodicity of the $SL(k, \mathbb{Z})$-action on $\mathbb{R}^k$.

We can now state our main result:

**Theorem A.** Let $F = F(A)$ be a free group of rank $k \geq 2$ with free basis $A = \{a_1, \ldots, a_k\}$ and let $\alpha : F \to \mathbb{Z}^k$ be the abelianization homomorphism.

Let $S \subseteq \mathbb{Z}^k$ be an $SL(k, \mathbb{Z})$-invariant subset and put $\bar{S} = \alpha^{-1}(S) \subseteq F$.

Then

1. For every $1 \leq p \leq \infty$ the strict asymptotic density $\rho_p(S)$ exists and, moreover, for every $1 \leq p \leq \infty$ we have $\rho_p(S) = \rho_\infty(S)$.
2. The strict annular density $\sigma_A(S)$ exist and, moreover, $\sigma_A(S) = \rho_\infty(S)$.

That is,

$$
\lim_{n \to \infty} \frac{1}{2} \left( \frac{\gamma_A(n-1, \{w \in F : \alpha(w) \in S\})}{\gamma_A(n-1, F)} + \frac{\gamma_A(n, \{w \in F : \alpha(w) \in S\})}{\gamma_A(n, F)} \right) =
\lim_{n \to \infty} \frac{\# \{z : z \in \mathbb{Z}^k, ||z||_\infty \leq n, \text{ and } z \in S\}}{\# \{z : z \in \mathbb{Z}^k, ||z||_\infty \leq n\}}.
$$

The requirement that $S$ be $SL(k, \mathbb{Z})$-invariant essentially says that the subset $S$ of $\mathbb{Z}^k$ is defined in “abstract” group-theoretic terms, not involving the specific choice of a free basis for $\mathbb{Z}^k$. Note that Proposition 2.2 below gives an explicit formula for $\rho_\infty(S)$ in Theorem A.

Our main application of Theorem A concerns the case where $S$ is the set of all “visible” points in $\mathbb{Z}^k$. A nonzero point $z$ of $\mathbb{Z}^k$ is called visible if the greatest common divisor of the coordinates of $z$ is equal to 1. This terminology is standard in number theory [34] and reflects the fact that if $z$ is visible then the line segment between the origin and $z$ does not contain any other integer lattice points. For a nonzero point $z \in \mathbb{Z}^k$ being visible is also equivalent to $z$ not being a proper power in $\mathbb{Z}^k$, that is, to $z$ generating a maximal cyclic subgroup of $\mathbb{Z}^k$. More generally, if $t \geq 1$ is an integer, we will say that $z \in \mathbb{Z}^k$ is $t$-visible if $z = z_1^t$ for some visible $z_1 \in \mathbb{Z}^k$, that is, if the greatest common divisor of the coordinates of $z$ is equal to $t$.

We want to “lift” this terminology to free groups.

**Definition 1.6** (Visible elements in free groups). Let $F = F(A)$ be a free group of rank $k \geq 2$ with free basis $A = \{a_1, \ldots, a_k\}$ and let $\alpha : F \to \mathbb{Z}^k$ be the abelianization homomorphism, that is, $\alpha(a_i) = e_i \in \mathbb{Z}^k$. We say that an element $w \in F$ is visible if $\alpha(w)$ is visible in $\mathbb{Z}^k$. Let $V$ be the set of visible elements of $F$. Similarly, for an integer $t \geq 1$ an element $w \in F$ is $t$-visible if $\alpha(w)$ is $t$-visible in $\mathbb{Z}^k$. We use $V_t$ to denote the set of all $t$-visible elements of $F$ and we use $U_t$ to denote the set of all $t$-visible elements of $\mathbb{Z}^k$.

Note that $V = V_1$ and that for every $t \geq 1$ the definition of $V_t$ does not depend on the choice of the free basis $A$ of $F$.

The following proposition giving the asymptotic density of the set of $t$-visible points in $\mathbb{Z}^k$ in terms of the Riemann zeta-function is well-known in number theory [9].

**Proposition 1.7.** For any integer $t \geq 1$ we have

$$
\rho_\infty(U_t) = \frac{1}{t^k \zeta(k)}.
$$
The case \( k = 2 \) and \( t = 1 \) of Proposition 1.7 was proved by Mertens in 1874 \cite{27}. (See also Theorem 332 of the classic book of Hardy and Wright \cite{17}.) Recall that \( \zeta(k) = \sum_{n=1}^{\infty} \frac{1}{n^k} \) and, in particular, \( \zeta(2) = \frac{\pi^2}{6} \).

It is therefore natural to investigate the asymptotic density of the set of visible elements in \( F \). As a direct corollary of Theorem A, of Proposition 2.9 below and of Proposition 1.7 we obtain:

**Theorem B.** Let \( F = F(A) \) be a free group of rank \( k \geq 2 \) with free basis \( A = \{a_1, a_2, \ldots, a_k\} \). Let \( t \geq 1 \) be an integer. Then the strict annular density \( \sigma_A(V_t) \) exists and

\[
\sigma_A(V_t) = \frac{1}{tk\zeta(k)}.
\]

Moreover, in this case

\[
0 < \frac{4k - 4}{(2k - 1)^2 tk\zeta(k)} \leq \liminf_{n \to \infty} \frac{\rho_A(n, V_t)}{\rho_A(n, F)} \leq \limsup_{n \to \infty} \frac{\rho_A(n, V_t)}{\rho_A(n, F)} \leq 1 - \frac{4k - 4}{(2k - 1)^2} \left( 1 - \frac{1}{tk\zeta(k)} \right) < 1.
\]

A result similar to Theorem B for counting conjugacy classes in \( F_k \) with primitive images in \( \mathbb{Z}^k \) has been recently independently obtained by Petridis and Risager \cite{33}.

For the case of the free group of rank two we compute the two “spherical densities” for the density of the set \( V_1 \), corresponding to even and odd \( n \) tending to infinity:

**Theorem C.** Let \( k = 2 \). We have

\[
\lim_{m \to \infty} \frac{\gamma_A(2m, V_1)}{\gamma_A(2m, F)} = \frac{2}{3\zeta(2)} = \frac{4}{\pi^2}
\]

and

\[
\lim_{m \to \infty} \frac{\gamma_A(2m - 1, V_1)}{\gamma_A(2m - 1, F)} = \frac{8}{\pi^2}.
\]

Theorem B implies that \( \sigma_A(V_1) = \frac{6}{\pi^2} \) in this case. Since the two limits in Theorem C are different, the statements of Theorem A and Theorem B cannot be substantially improved. This fact underscores the conclusion that annular density is the right kind of notion for measuring the sizes of subsets of free groups, where the abelianization map is concerned.

We apply Theorem B to compute the annular density of test elements in a free group of rank two. Recall that an element \( g \in G \) is called a test element if every endomorphism of \( G \) fixing \( g \) is actually an automorphism of \( G \). It is easy to see that for two conjugate elements \( g_1, g_2 \in G \) the element \( g_1 \) is a test element if and only if \( g_2 \) is also a test element and thus the property of being a test element depends only on the conjugacy class of an element \( g \). The notion of a test element was introduced by Shpilrain \cite{39} and has since become a subject of active research both in group theory and in the context of other algebraic structures such as polynomial algebras and Lie algebras. (See, for example, \cite{12, 13, 24, 29, 32, 37, 40, 42}.) It turns out that studying test elements in a particular group \( G \) produces interesting information about the automorphism group of \( G \).

Here we prove:
Theorem D. Let $F = F(a, b)$ be a free group of rank two with free basis $A = \{a, b\}$. Then for the set $T$ of all test elements in $F$ the strict annular density exists and

$$\sigma_A(T) = 1 - \frac{6}{\pi^2}.$$ 

Moreover,

$$0 < \frac{4}{9}(1 - \frac{6}{\pi^2}) \leq \liminf_{n \to \infty} \frac{\rho_A(n, T)}{\rho_A(n, F)} \leq \limsup_{n \to \infty} \frac{\rho_A(n, T)}{\rho_A(n, F)} \leq 1 - \frac{8}{3\pi^2} < 1.$$ 

By a result of Turner [43], an element of $F$ is a test element if and only if it does not belong to a proper retract of $F$. Therefore Theorem D implies that the strict annular density of the union of all proper retracts of $F(a, b)$ is $\frac{2}{3\pi^2}$. In Theorem D above we have $\frac{4}{9}(1 - \frac{6}{\pi^2}) \approx 0.1742$, $1 - \frac{6}{\pi^2} \approx 0.7298$. Thus Theorem D shows that being a test element is an “intermediate” property in the free group of rank two. More generally, Theorem D implies that, for every $k \geq 2$ and for $N$ sufficiently large, the set $V_N$ of $N$-visible elements in $F_k$ has strictly positive annular density arbitrarily close to 0 while the set $S_N = \bigcup_{t=1}^N V_t$ has annular density less than but arbitrarily close to 1. It is well-known that every positive rational number has an “Egyptian fraction” representation as a finite sum of distinct terms of the form $\frac{1}{n}$. It does not seem clear what values can be obtained as finite sums of distinct terms of the form $\frac{1}{n^2}$ and there are excluded intervals. In particular, if such a sum uses 1, it is at least 1 while if 1 is not used then the sum is at most $\frac{\pi^2}{6} - 1$. Multiplying by the scale factor $\frac{1}{\zeta(2)}$, we see that we cannot obtain an annular density in the open interval $(1 - \frac{6}{\pi^2}, \frac{8}{3\pi^2})$ by taking a finite union of the sets $V_t$ (Proposition 2.2 below shows that the same is true for infinite unions). It is interesting to note that the probabilities of being a test element or of not being a test element are the boundary points of this excluded interval.

Nathan Dunfield and Dylan Thurston recently proved [11] that for a two-generator one-relator group being free-by-cyclic is an intermediate property. While they do not provide an exact value for the asymptotic density (nor do they prove that either the strict asymptotic density or the strict annular density exist), they show that it is strictly between 0 and 1. Computer experiments by Kapovich and Schupp, by Mark Sapir and by Dunfield and Thurston indicate that in the two-generator case this asymptotic density is greater than 0.9.

The authors are grateful to Laurent Bartholdi, John D’Angelo, Iwan Duursma, Kevin Ford, Steve Lalley, Alexander Ol’shanskii, Yuval Peres, Yannis Petridis, Alexandru Zaharescu and Andrzej Zuk for very helpful conversations.

2. Comparing densities in $\mathbb{Z}^k$ and in $F_k$

Convention 2.1. Throughout this section let $S \subseteq \mathbb{Z}^k$ be as in Theorem A and let $\delta := \mathcal{P}_\infty(S)$.

We can now prove that for every $SL(k, \mathbb{Z})$-invariant subset $S$ of $\mathbb{Z}^k$ the strict asymptotic density $\rho_\infty(S)$ exists. Recall that Proposition 1.7 stated in the introduction gives the precise value of the strict asymptotic density of the set of all $t$-visible elements in $\mathbb{Z}^k$. The crucial points of the proof below are that the complement of an $SL(k, \mathbb{Z})$-invariant is also $SL(k, \mathbb{Z})$-invariant and that $\sum_{i=1}^\infty \frac{1}{r^\chi(i)} = 1$. 

Proposition 2.2. Let \( Y \subseteq \mathbb{Z}^k \) be a nonempty \( SL(k, \mathbb{Z}) \)-invariant subset that does not contain \( 0 \in \mathbb{Z}^k \). Let \( I \) be the set of all integers \( t \geq 1 \) such that there exists a \( t \)-visible element in \( Y \). Then

1. \( Y = \bigcup_{t \in I} U_t \).
2. The strict asymptotic density \( \rho_\infty(Y) \) exists and
   \[ \rho_\infty(Y) = \sum_{t \in I} \rho(U_t) = \sum_{t \in I} \frac{1}{t^k \zeta(k)}. \]

Proof. Observe first that
\[ \sum_{t=1}^{\infty} \frac{1}{t^k \zeta(k)} = \frac{1}{\zeta(k)} \sum_{t=1}^{\infty} \frac{1}{t^k} = \frac{\zeta(k)}{\zeta(k)} = 1. \]

Since \( k \geq 2 \), two nonzero elements \( z, z' \in \mathbb{Z}^k \) lie in the same \( SL(k, \mathbb{Z}) \)-orbit if and only if the greatest common divisors of the coordinates of \( z \) and of \( z' \) are equal. Thus every \( SL(k, \mathbb{Z}) \)-orbit of a nonzero element of \( \mathbb{Z}^k \) has the form \( U_t \) for some \( t \geq 1 \). This implies part (1) of Proposition 2.2.

Let \( I' := \{ t \in \mathbb{Z} : t \geq 1, t \notin I \} \). If either \( I \) or \( I' \) is finite, part (2) of Proposition 2.2 follows directly from Proposition 1.7. Suppose now that both \( I \) and \( I' \) are infinite and let \( Y' := \mathbb{Z}^k \setminus (Y \cup \{0\}) = \bigcup_{t \in I'} U_t \).

For every finite subset \( J \subseteq I \) let \( Y_J := \bigcup_{t \in J} U_t \). Since \( Y_J \subseteq Y \), it follows that
\[ \liminf_{n \to \infty} \frac{\#\{z \in Y : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}} \geq \rho_\infty(Y_J) = \sum_{t \in J} \frac{1}{t^k \zeta(k)}. \]

Since this is true for every finite subset of \( I \), we conclude that
\[ \liminf_{n \to \infty} \frac{\#\{z \in Y : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}} \geq \sum_{t \in I} \frac{1}{t^k \zeta(k)}. \]

The same argument applies to the \( SL(k, \mathbb{Z}) \)-invariant set \( Y' \) and therefore:
\[ \liminf_{n \to \infty} \frac{\#\{z \in Y' : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}} \geq \sum_{t \in I'} \frac{1}{t^k \zeta(k)}. \]

This implies
\[ 1 - \liminf_{n \to \infty} \frac{\#\{z \in Y' : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}} \leq 1 - \sum_{t \in I'} \frac{1}{t^k \zeta(k)} = \left(1 - \sum_{t \in I} \frac{1}{t^k \zeta(k)}\right) \Rightarrow \]
\[ \limsup_{n \to \infty} \left(1 - \frac{\#\{z \in Y' : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}}\right) \leq 1 - \sum_{t \in I'} \frac{1}{t^k \zeta(k)} \Rightarrow \]
\[ \limsup_{n \to \infty} \frac{\#\{z \in Y : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}} \leq 1 - \sum_{t \in I'} \frac{1}{t^k \zeta(k)} = \sum_{t \in I} \frac{1}{t^k \zeta(k)}. \]

Hence
\[ \lim_{n \to \infty} \frac{\#\{z \in Y : \|z\|_\infty \leq n\}}{\#\{z \in \mathbb{Z}^k : \|z\|_\infty \leq n\}} = \sum_{t \in I} \frac{1}{t^k \zeta(k)}, \]
as required. \( \square \)

Recall that \( S \subseteq \mathbb{Z}^k \) is an \( SL(k, \mathbb{Z}) \)-invariant subset and that \( \delta = \overline{\rho}_\infty(S) \). Proposition 2.2 implies that in fact \( \delta = \rho_\infty(S) \).
It is well known that if $\Omega \subseteq \mathbb{R}^k$ is a “nice” bounded open set then the Lebesgue measure $\lambda(\Omega)$ can be computed as

$$\lambda(\Omega) = \lim_{r \to \infty} \frac{\#(\mathbb{Z}^k \cap r\Omega)}{r^k}.$$ 

Here we say that a bounded open subset of $\mathbb{R}^k$ is “nice” if its boundary is piecewise smooth.

We need a similar formula for counting the points of $S$. For a real number $r \geq 1$ and a nice bounded open set $\Omega \subseteq \mathbb{Z}^k$ let

$$\mu_{r,S}(\Omega) := \frac{\#(S \cap r\Omega)}{r^k}.$$ 

**Proposition 2.3.** For any nice bounded open set $\Omega \subseteq \mathbb{Z}^k$ we have

$$\lim_{r \to \infty} \mu_{r,S}(\Omega) = \delta\lambda(\Omega).$$

**Proof.** Each $\mu_{r,S}$ can be regarded as a measure on $\mathbb{R}^k$. We prove the theorem by showing that the $\mu_{r,S}$ weakly converge to $\delta\lambda$ as $r \to \infty$, where $\lambda$ is the Lebesgue measure.

By Helly’s theorem there exists a sequence $(r_i)_{i=1}^{\infty}$ with $\lim_{i \to \infty} r_i = \infty$ such that the sequence $\mu_{r_1,S}, \mu_{r_2,S}, \ldots$ is weakly convergent to some limiting measure. We now show that for every such convergent subsequence of $\mu_{r_i,S}$ the limiting measure is indeed equal to $\delta\lambda$, where $\lambda$ is the Lebesgue measure.

Indeed, suppose that $\sigma = (r_i)_{i=1}^{\infty}$ is a sequence with $\lim_{i \to \infty} r_i = \infty$ such that the sequence $\mu_{r_i,S}$ converges to the limiting measure $\mu_\sigma = \lim_{i \to \infty} \mu_{r_i,S}$. Every $\mu_{r_i,S}$ is invariant with respect to the natural $SL(k, \mathbb{Z})$-action since this action preserves the set $S$ and also commutes with homotheties of $\mathbb{R}^k$ centered at the origin. Therefore the limiting measure $\mu_\sigma$ is also $SL(k, \mathbb{Z})$-invariant.

Moreover, the measures $\mu_{r,S}$ are dominated by the measures $\lambda_r$ defined as $\lambda_r(\Omega) = \frac{\#(\mathbb{Z}^k \cap r\Omega)}{r^k}$. Since, as observed earlier, the measures $\lambda_r$ converge to the Lebesgue measure $\lambda$, it follows that $\mu_\sigma$ is absolutely continuous with respect to $\lambda$. It is known that the natural action of $SL(k, \mathbb{Z})$ on $\mathbb{R}^k$ is ergodic with respect to $\lambda$. (See, for example, Zimmer’s classic monograph [45].) Therefore $\mu_\sigma$ is a constant multiple $c\lambda$ of $\lambda$. The constant $c$ can be computed explicitly for a set such as the open unit ball $B$ in the $||.||_\infty$ norm on $\mathbb{R}^k$ defining the length function $\ell$ on $\mathbb{Z}^k$.

By assumption we know that

$$\lim_{r \to \infty} \frac{\#\{z \in \mathbb{Z}^k : z \in S \cap rB\}}{\#\{z \in \mathbb{Z}^k : z \in rB\}} = \delta.$$ 

We also have

$$\lim_{r \to \infty} \frac{\#\{z \in \mathbb{Z}^k : z \in rB\}}{r^k} = \lambda(B)$$

and hence

$$\lim_{r \to \infty} \frac{\#\{z \in \mathbb{Z}^k : z \in S \cap rB\}}{r^k} = \delta\lambda(B).$$

Therefore $c = \delta$ and $\mu_\sigma = \delta\lambda$. The above argument in fact shows that every convergent subsequence, with $r \to \infty$, of $\mu_{r,S}$ converges to $\delta\lambda$ and therefore $\lim_{r \to \infty} \mu_{r,S} = \delta\lambda$.
Remark 2.4. Let $1 \leq p \leq \infty$. Then the open unit ball in $\mathbb{R}^k$ with respect to $\|\cdot\|_p$ is "nice". Proposition 2.3 applied to $\Omega$ being this ball, implies that $\rho_p(S) = \rho_\infty(S) = \delta$.

Convention 2.5. As always, $F = F(a_1, \ldots, a_k)$ is the free group of rank $k \geq 2$ with free basis $A = \{a_1, \ldots, a_k\}$ and $\alpha : F \to \mathbb{Z}^k$ is the abelianization homomorphism sending $a_i$ to $e_i$ in $\mathbb{Z}^k$. We will denote $\alpha(w)$ by $\overline{w}$. For $n \geq 1$, $B_F(n)$ denotes the set of all $w \in F$ with $|w|_A \leq n$. Also, for a point $x = (x_1, \ldots, x_k) \in \mathbb{R}^k$ we denote by $\|x\|$ the $\|\cdot\|_2$-norm of $x$, that is $\|x\| = \sqrt{\sum_{i=1}^k x_i^2}$.

Notation 2.6. For an integer $n \geq 1$ and a point $x \in \mathbb{R}^k$ let

$$p_n(x) = \frac{\gamma_A(n-1, \{f \in F : \alpha(f) = x/\sqrt{n}\})}{2\gamma_A(n-1, F)} + \frac{\gamma_A(n, \{f \in F : \alpha(f) = x/\sqrt{n}\})}{2\gamma_A(n, F)}.$$  

Thus $p_n$ is a distribution supported on finitely many points of $\frac{1}{\sqrt{n}}\mathbb{Z}^k$.

We need the following facts about the sequence of distributions $p_n$. Of these the most significant is part (2) which is a local limit theorem in our context. It was obtained by Rivin [35] and, independently and via different methods, by Sharp [38] (specifically, we use Theorem 1 of [35] for part (2) of Proposition 2.7 below).

Proposition 2.7. [35, 38] Let $k \geq 2$ and let $p_n$ be as above. Then:

1. The sequence of distributions $p_n$ converges weakly to a normal distribution $\mathcal{N}$, with density $\nu$.
2. We have $\sup_{x \in \mathbb{Z}^k/\sqrt{n}} |p_n(x)n^{k/2} - \nu(x)| \to 0$ as $n \to \infty$.
3. We have $\lim_{c \to \infty} \sum \{p_n(x) : x \in \mathbb{Z}^k/\sqrt{n} \text{ and } \|x\| \geq c\} = 0$.

Theorem 2.8. Let $\Omega \subseteq \mathbb{R}^k$ be a nice bounded open set. Then

$$\lim_{n \to \infty} \sum_{x \in S_\Omega \cap \sqrt{n}\Omega} p_n(x/\sqrt{n}) = \delta_{\mathcal{N}}(\Omega).$$

Proof. We have

$$\sum_{x \in \mathbb{Z}^k/\sqrt{n}\Omega} p_n(x/\sqrt{n}) = \sum_{y \in \mathbb{Z}^k/\sqrt{n}\Omega} p_n(y) = n^{-k/2} \sum_{y \in \mathbb{Z}^k/\sqrt{n}\Omega} \nu(y) + n^{-k/2} \sum_{y \in \mathbb{Z}^k/\sqrt{n}\Omega} (n^{k/2} p_n(y) - \nu(y)).$$

The local limit theorem in part (2) of Proposition 2.7 tells us that, as $n \to \infty$, each summand $n^{k/2} p_n(y) - \nu(y)$ of the second sum in the last line of equation above converges to zero and hence so does their Cesaro mean. Proposition 2.8 implies that, as $n \to \infty$, the first summand $n^{-k/2} \sum_{y \in \mathbb{Z}^k/\sqrt{n}\Omega} \nu(y)$ converges to $\delta \int_{\Omega} \nu d\lambda = \delta_{\mathcal{N}}(\Omega)$.

□
We can now compute the strict asymptotic density of $\tilde{S} = \alpha^{-1}(S)$ in $F$ and obtain Theorem A.

Proof of Theorem A. Recall that $S \subseteq \mathbb{Z}^k$ is an $SL(k, \mathbb{Z})$-invariant set and that $\delta = \varpi_{\infty}(S)$. Proposition B.2 implies that in fact $\rho_{\infty}(S)$ exists and $\delta = \rho_{\infty}(S)$. Moreover, as we have seen in Remark B.4, for every $1 \leq p \leq \infty$ the strict asymptotic density $\rho_p(S)$ exists and $\rho_p(S) = \delta = \rho_{\infty}(S)$. This proves part (1) of Theorem A.

To prove part (2) of Theorem A we need to establish that the strict annular density $\sigma_A(S)$ exists and that $\sigma_A(S) = \delta$.

For $c > 0$ denote $\Omega_c := \{x \in \mathbb{R}^k : ||x|| < c\}$. Then $\lim_{c \to \infty} \mathcal{H}(\Omega_c) = 1$. Let $\epsilon > 0$ be arbitrary. Choose $c > 0$ such that

$$|\mathcal{H}(\Omega_c) - 1| \leq \epsilon/3$$

and such that

$$\lim_{n \to \infty} \sum \{p_n(x) : x \in \mathbb{Z}^k/\sqrt{n} \text{ and } ||x|| \geq c\} \leq \epsilon/6.$$

By Theorem B.2 and the above formula there is some $n_0 \geq 1$ such that for all $n \geq n_0$ we have

$$\left| \sum_{x \in S \cap \sqrt{n}\Lambda_c} p_n(x/\sqrt{n}) - \delta\mathcal{H}(\Omega_c) \right| \leq \epsilon/3$$

and

$$\sum \{p_n(x) : x \in \mathbb{Z}^k/\sqrt{n} \text{ and } ||x|| \geq c\} \leq \epsilon/3.$$

Let

$$Q(n) := \frac{\gamma_A(n-1, \{w \in F : \overline{w} \in S\})}{2\gamma_A(n-1, F)} + \frac{\gamma_A(n, \{w \in F : \overline{w} \in S\})}{2\gamma_A(n, F)}.$$

For $n \geq n_0$ we have

$$Q(n) = \frac{\# \{w \in F : \overline{w} \in S, |w|_A = n-1 \text{ and } ||\overline{w}|| < c\sqrt{n} \}}{2\gamma_A(n-1, F)} + \frac{\# \{w \in F : \overline{w} \in S, |w|_A = n \text{ and } ||\overline{w}|| < c\sqrt{n} \}}{2\gamma_A(n, F)} + \frac{\# \{w \in F : \overline{w} \in S, |w|_A = n-1 \text{ and } ||\overline{w}|| \geq c\sqrt{n} \}}{2\gamma_A(n-1, F)} + \frac{\# \{w \in F : \overline{w} \in S, |w|_A = n \text{ and } ||\overline{w}|| \geq c\sqrt{n} \}}{2\gamma_A(n, F)}$$

$$= \sum_{x \in S \cap \sqrt{n}\Lambda_c} p_n(x/\sqrt{n}) + \sum_{x \in S \cap \sqrt{n}\mathbb{R}^k}\overline{\Lambda_c} p_n(x/\sqrt{n}).$$

In the last line of the above equation, the first sum differs from $\delta\mathcal{H}(\Omega_c)$ by at most $\epsilon/3$ since $n \geq n_0$ and the second sum is $\leq \epsilon/3$ by the choice of $c$ and $n_0$. Therefore, again by the choice of $c$, we have $|Q(n) - \delta| \leq \epsilon$. Since $\epsilon > 0$ was arbitrary, this implies that $\lim_{n \to \infty} Q(n) = \delta$, as claimed.

The following observation shows how to estimate the asymptotic density in terms of the annular density.
Proposition 2.9. Let \( Y \subseteq F \) be a subset such that the strict annular density \( \delta = \sigma_A(Y) \) exists. Then

\[
\frac{4k - 4}{(2k - 1)^2} \delta \leq \liminf_{n \to \infty} \frac{\rho_A(n, S)}{\rho_A(n, F)} \leq \limsup_{n \to \infty} \frac{\rho_A(n, S)}{\rho_A(n, F)} \leq 1 - \frac{4k - 4}{(2k - 1)^2}(1 - \delta).
\]

In particular, if \( 0 < \delta < 1 \) then

\[
0 < \liminf_{n \to \infty} \frac{\rho_A(n, S)}{\rho_A(n, F)} \leq \limsup_{n \to \infty} \frac{\rho_A(n, S)}{\rho_A(n, F)} < 1.
\]

Proof. Note that for \( n \geq 1 \) we have \( \gamma_A(n, F) = 2k(2k - 1)^n \) and that, up to an additive constant, \( \rho_A(n, F) = \frac{k}{k - 1}(2k - 1)^n \). Denote \( a_n = \gamma_A(n, Y) \). We have

\[
\delta = \lim_{n \to \infty} \frac{1}{2} \left( \frac{a_{n-1}}{2k(2k - 1)^{n-2}} + \frac{a_n}{2k(2k - 1)^{n-1}} \right) = \frac{1}{2} \lim_{n \to \infty} \frac{a_{n-1} \frac{2k-1}{2k} + a_n \frac{2k-1}{2k} - 1}{k(2k - 1)^{n-1}}.
\]

Therefore

\[
\liminf_{n \to \infty} \frac{\rho_A(n, Y)}{\rho_A(n, F)} = \liminf_{n \to \infty} \frac{a_1 + \cdots + a_n}{k(2k - 1)^n} \geq \liminf_{n \to \infty} \frac{a_{n-1} + a_n}{k(2k - 1)^n} = \frac{2k - 2}{2k - 1} \liminf_{n \to \infty} \frac{a_{n-1} \frac{2k-1}{2k} + a_n \frac{2k-1}{2k} - 1}{k(2k - 1)^{n-1}} = \frac{4k - 4}{(2k - 1)^2} \liminf_{n \to \infty} \frac{1}{2} \left( \frac{a_{n-1} \frac{2k-1}{2k} + a_n \frac{2k-1}{2k}}{k(2k - 1)^{n-1}} \right) = \frac{4k - 4}{(2k - 1)^2} \delta.
\]

Applying the same argument to the set \( F - Y \), we get

\[
\liminf_{n \to \infty} \frac{\rho_A(n, F - Y)}{\rho_A(n, F)} = 1 - \frac{4k - 4}{(2k - 1)^2}(1 - \delta).
\]

Therefore

\[
\limsup_{n \to \infty} \frac{\rho_A(n, Y)}{\rho_A(n, F)} = 1 - \liminf_{n \to \infty} \frac{\rho_A(n, F - Y)}{\rho_A(n, F)} \leq 1 - \frac{4k - 4}{(2k - 1)^2}(1 - \delta).
\]

\( \square \)

3. Spherical densities

In this section we will prove Theorem 3 from the Introduction and, for the case of \( k = 2 \), compute the “spherical densities”

\[
\lim_{m \to \infty} \frac{\gamma_A(2m, V_1)}{\gamma_A(2m, F)}
\]

and

\[
\lim_{m \to \infty} \frac{\gamma_A(2m - 1, V_1)}{\gamma_A(2m - 1, F)}.
\]

This is done by computing the “spherical densities” for the set \( V_1(\epsilon) \subseteq F \) consisting of all points of \( V_1 \) of even length and comparing it with the strict asymptotic density of the set \( U_1(\epsilon) \subseteq \mathbb{Z}^k \) of all elements of \( \mathbb{Z}^k \) of even \( \| \cdot \|_{\infty} \)-length. The key point is that for \( n = 2m \) we have \( \gamma_A(2m - 1, V_1(\epsilon)) = 0 \) and \( \gamma_A(2m, V_1) = \gamma_A(2m, V_1(\epsilon)) \). Therefore for the quantities from the definition of annular density we have

\[
\frac{1}{2} \left( \frac{\gamma_A(2m, V_1(\epsilon))}{\gamma_A(2m, F)} + \frac{\gamma_A(2m - 1, V_1(\epsilon))}{\gamma_A(2m - 1, F)} \right) = \frac{\gamma_A(2m, V_1(\epsilon))}{2\gamma_A(2m, F)} = \frac{\gamma_A(2m, V_1)}{2\gamma_A(2m, F)}.
\]
This allows us to essentially repeat the proof of Theorem 2.1, applied to the sets \( U_1(e) \) and \( V_1(e) = \alpha^{-1}(U_1(e)) \), except that instead of ergodicity of the action of \( SL(k, \mathbb{Z}) \) we use the ergodicity of the action on \( \mathbb{R}^k \) of a congruence subgroup of \( SL(k, \mathbb{Z}) \) that leaves \( U_1(e) \) invariant.

**Convention 3.1.** We say that an element \( z = (z_1, \ldots, z_k) \in \mathbb{Z}^k \) is even if \( ||z||_1 = |z_1| + \cdots + |z_k| \) is even and that \( z \) is odd if \( ||z||_1 \) is odd. Similarly, \( w \in F \) is even if \( |w|_A \) is even and \( w \in F \) is odd if \( |w|_A \) is odd. Note that \( w \in F \) is even if and only if \( \alpha(w) \in \mathbb{Z}^k \) is even.

Let \( G_k \) be the set of all \( M \in SL(k, \mathbb{Z}) \) such that \( M = I_k \) in \( SL(k, \mathbb{Z}/2\mathbb{Z}) \). Thus \( G_k \) is a finite index subgroup of \( SL(k, \mathbb{Z}) \) also known as the 2-congruence subgroup. Denote by \( \mathbb{Z}^k(e) \) the set of all even elements in \( \mathbb{Z}^k \). Also denote \( U_1(e) := U_1 \cap \mathbb{Z}^k(e) \). Observe that \( \mathbb{Z}^k(e) \) and \( U_1(e) \) are \( G_k \)-invariant and that \( V_1(e) = \alpha^{-1}(U_1(e)) \). (The actual set-wise stabilizer of \( \mathbb{Z}^k(e) \) in \( SL(k, \mathbb{Z}) \) contains \( G_k \) as a subgroup of finite index.)

**Proposition 3.2.** Let \( S \subseteq \mathbb{Z}^k \) be a subset such that \( \delta = \rho_\infty(S) \) exists and such that \( S \) is \( G_k \)-invariant. Then for every bounded nice open set \( \Omega \subseteq \mathbb{R}^k \) we have

\[
\lim_{r \to \infty} \mu_{r,S}(\Omega) = \delta \lambda(\Omega).
\]

**Proof.** The proof is the same as for Proposition 2.8. The only difference is that instead of ergodicity of the \( SL(k, \mathbb{Z}) \)-action on \( \mathbb{R}^k \) we use ergodicity of the \( G_k \)-action on \( \mathbb{R}^k \) with respect to the Lebesgue measure (see 15 for the proof of this ergodicity). \( \square \)

Let \( p_n(x) \) be defined exactly as in Notation 2.10.

**Theorem 3.3.** Let \( \Omega \subseteq \mathbb{R}^k \) be a nice bounded open set. Let \( S \subseteq \mathbb{Z}^k \) be a \( G_k \)-invariant subset such that \( \delta := \rho_\infty(S) \) exists. Then

\[
\lim_{n \to \infty} \sum_{x \in S \cap \sqrt{n}\Omega} p_n(x/\sqrt{n}) = \delta \Omega(\Omega).
\]

**Proof.** The proof is exactly the same as that of Theorem 2.8 with the only change that instead of Proposition 2.8 we use Proposition 3.2 \( \square \)

**Convention 3.4.** From now and until the end of this section we assume that \( k = 2 \).

**Proposition 3.5.** We have

\[
\rho_\infty(U_1(e)) = \frac{1}{3} \rho_\infty(U_1) = \frac{1}{3\zeta(2)}.
\]

**Proof.** Let \( r, s \geq 1 \) be real numbers. For \( X, Y \in \{ A, O, E \} \) we denote by \( XY(r, s) \) the number of all \( z = (z_1, z_2) \in U_1 \) such that \( 0 \leq z_1 < r, 0 \leq z_2 < s \) and such that the parity of \( z_1 \) is \( X \) and the parity of \( z_2 \) is \( Y \). Here \( A \) stands for “any”, \( E \) stands for “even” and \( O \) stands for “odd”.

Let \( n \gg 1, m \gg 1 \) be integers. Then \( AA(n, m) = nm \). We will also use \( =' \) to signify the equality up to an additive error term that is \( o(nm) \). Note that
$EE(n,m) = 0$. Then we have

$$EO(n,m) = AO(n/2, m) = AA(n/2, m) - AE(n/2, m) = 
\frac{1}{2} AA(n, m) - \frac{1}{2} EO(n, m).$$

Therefore

$$\frac{3}{2} EO(n, m) = \frac{1}{2} AA(n, m) \implies EO(n, m) = \frac{1}{3} AA(n, m).$$

Hence $EO(n, m) + OE(n, m) = \frac{2}{3} AA(n, m)$ which implies

$$OO(n, m) = OO(n, m) + EE(n, m) = \frac{1}{3} AA(n, m).$$

Since $\rho_{\infty}(U_1) = \frac{1}{\zeta(2)}$, we have

$$\lim_{n \to \infty} \frac{AA(n,n)}{n^{3/2}} = \frac{1}{\zeta(2)}$$

Therefore

$$\lim_{n \to \infty} \frac{EE(n,n) + OO(n,n)}{n^{3/2}} = \frac{1}{3\zeta(2)},$$

which implies $\rho_{\infty}(U_1(e)) = \frac{1}{3\zeta(2)}$, as required.

We can now compute the limits for the spherical densities of the set of visible points for even and odd $n$ tending to infinity for the case $k = 2$.

**Theorem 3.6.** Let $k = 2$. We have

$$\lim_{m \to \infty} \frac{\gamma_A(2m, V_1)}{\gamma_A(2m, F)} = \frac{2}{3\zeta(2)} = \frac{4}{\pi^2}$$

and

$$\lim_{m \to \infty} \frac{\gamma_A(2m - 1, V_1)}{\gamma_A(2m - 1, F)} = \frac{8}{\pi^2}.$$  

**Proof.** The proof is essentially the same as that of Theorem A. We present the details for completeness.

For $c > 0$ denote $\Omega_c := \{ x \in \mathbb{R}^2 : ||x|| < c \}$. Then $\lim_{c \to \infty} \mathcal{M}(\Omega_c) = 1$. Let $\epsilon > 0$ be arbitrary. Choose $c > 0$ such that

$$|\mathcal{M}(\Omega_c) - 1| \leq \epsilon/3$$

and such that

$$\lim_{n \to \infty} \sum_{x \in \mathbb{Z}^2/\sqrt{n}} \{ p_n(x) : x \in \mathbb{Z}^2/\sqrt{n} \text{ and } ||x|| \geq c \} \leq \epsilon/6.$$

By Theorem 3.3 and the above formula there is some $n_0 \geq 1$ such that for all $n \geq n_0$ we have

$$\left| \sum_{x \in \mathbb{Z}^2/\sqrt{n}} p_n(x/\sqrt{n}) - \frac{1}{3\zeta(2)} \mathcal{M}(\Omega_c) \right| \leq \epsilon/3$$

and

$$\sum_{x \in \mathbb{Z}^2/\sqrt{n}} \{ p_n(x) : x \in \mathbb{Z}^2/\sqrt{n} \text{ and } ||x|| \geq c \} \leq \epsilon/3.$$
For an even $n \geq 2$ let

$$Q(n) := \frac{\gamma_A(n-1, \{w \in F : \|w\|_A = n-1, \|w\| < c\sqrt{n}\})}{2\gamma_A(n-1, F)} + \frac{\gamma_A(n, \{w \in F : \|w\|_A = n, \|w\| < c\sqrt{n}\})}{2\gamma_A(n, F)} + \frac{\gamma_A(n, \{w \in F : \|w\|_A = n-1, \|w\| \geq c\sqrt{n}\})}{2\gamma_A(n-1, F)} + \frac{\gamma_A(n, \{w \in F : \|w\|_A = n, \|w\| \geq c\sqrt{n}\})}{2\gamma_A(n, F)} + \sum_{x \in U_1(e) \cap \sqrt{n} \Omega_c} p_n(x/\sqrt{n}) + \sum_{x \in U_1(e) \cap [\mathbb{R}^2 - \sqrt{n} \Omega_c]} p_n(x/\sqrt{n})$$

In the above equality we use the fact that $n$ is even and all the points of $U_1(e)$ are even.

For an even $n \geq n_0$ we have

$$Q(n) = \frac{\#\{w \in F : \|w\|_A = n-1, \|w\| < c\sqrt{n}\}}{2\gamma_A(n-1, F)} + \frac{\#\{w \in F : \|w\|_A = n, \|w\| < c\sqrt{n}\}}{2\gamma_A(n, F)} + \frac{\#\{w \in F : \|w\|_A = n-1, \|w\| \geq c\sqrt{n}\}}{2\gamma_A(n-1, F)} + \frac{\#\{w \in F : \|w\|_A = n, \|w\| \geq c\sqrt{n}\}}{2\gamma_A(n, F)} + \sum_{x \in U_1(e) \cap \sqrt{n} \Omega_c} p_n(x/\sqrt{n}) + \sum_{x \in U_1(e) \cap [\mathbb{R}^2 - \sqrt{n} \Omega_c]} p_n(x/\sqrt{n})$$

In the last line of the above equation, the first sum differs from $\frac{1}{\zeta(2)} \Re(\Omega_c)$ by at most $\epsilon/3$ since $n \geq n_0$, and the second sum is $\leq \epsilon/3$ by the choice of $c$ and $n_0$. Therefore, again by the choice of $c$, we have $|Q(n) - \frac{1}{\zeta(2)}| \leq \epsilon$. Since $\epsilon > 0$ was arbitrary, this implies that $\lim_{m \to \infty} Q(2m) = \frac{1}{3\zeta(2)}$. Therefore

$$\lim_{m \to \infty} \frac{\gamma_A(2m, V_1)}{\gamma_A(2m, F)} = 2 \lim_{m \to \infty} Q(2m) = \frac{2}{3\zeta(2)} = \frac{4}{\pi^2}.$$ 

Together with the conclusion of Theorem [3] this implies that

$$\lim_{m \to \infty} \frac{\gamma_A(2m-1, V_1)}{\gamma_A(2m-1, F)} = \frac{8}{\pi^2},$$

as claimed. \qed

4. Test elements in the free group of rank two

A subgroup $H$ of a group $G$ is called a retract of $G$ if there exists a retraction from $G$ to $H$, that is, an endomorphism $\phi : G \to G$ such that $H = \phi(G)$ and that $\phi|_H = \text{Id}_H$. A retract $H \leq G$ is proper if $H \neq G$ and $H \neq 1$.

The following result is due to Turner [43]:

**Proposition 4.1.** Let $F$ be a free group of finite rank $k \geq 2$ and let $w \in F$. Then $w$ is a test element in $F$ if and only if $w$ does not belong to a proper retract of $F$. 
If $F$ is a free group of rank two, then a proper retract of $F$ is necessarily cyclic. The following explicit characterization of retracts in this case is actually Exercise 25 on page 103 of Magnus, Karrass, Solitar [20]. We present a proof here for completeness.

**Lemma 4.2.** Let $F$ be a free group of rank two and let $H = \langle h \rangle \leq F$ be an infinite cyclic subgroup of $F$.

Then $H$ is a retract of $F$ if and only if there is a free basis $\{a, b\}$ of $F$ such that $b$ belongs to the normal closure of $a$ in $F$. In particular, if $H$ is a retract of $F$ then $H$ is a maximal cyclic subgroup of $F$.

**Proof.** Suppose first that $H$ is a retract of $F$ and that $\phi : F \to F$ is a retraction with $\phi(F) = H$. Choose a free basis $x, y$ of $F$. Since $H = \langle h \rangle = \langle \phi(x), \phi(y) \rangle \leq F$ is infinite cyclic, the pair $(x, y)$ is Nielsen equivalent to the pair $(h, 1)$. Applying the same sequence of Nielsen transformations to $(x, y)$ we obtain a free basis $(a, b)$ of $F$ such that $\phi(a) = h$ and $\phi(b) = 1$. Then the kernel of $\phi$ is the normal closure of $b$ in $F$.

Since $\phi$ is a retraction onto $H$, we have $\phi(b) = h = \phi(a)$. Hence $a^{-1}h \in \ker(\phi)$ and therefore $h = ac$, where $c$ belongs to the kernel of $\phi$, that is, to the normal closure of $b$, as required.

Suppose now that for some free basis $a, b$ of $F$ we have $h = ac$ where $c$ belongs to the normal closure of $b$ in $F$. Consider the endomorphism $\psi : F \to F$ defined by $\psi(a) = h$, $\psi(b) = 1$. Then, clearly, $\psi(h) = h$ and $\psi$ is a retraction from $F$ to $H$. $\Box$

We can now obtain an explicit characterization of test elements in free group $F$ of rank with free basis $A = \{a, b\}$. We identify the abelianization of $F$ with $\mathbb{Z}^2$ so that $\overline{a} = (1, 0)$ and $\overline{b} = (0, 1)$. If $x \in A$ and $w \in F$, then $w_x$ denotes the exponent sum on $x$ in $w$ when $w$ is written as a freely reduced word in $A$ and $\overline{w}$ denotes the image of $w$ in the abelianization of $F$. Thus $\overline{w} = (w_a, w_b)$.

**Proposition 4.3.** Let $F$ be a free group of rank two. Let $w \in F$ be a nontrivial element that is not a proper power in $F$.

Then $w$ is a test element in $F$ if and only if there exists an integer $n \geq 2$ such that $\overline{w}$ is an $n$-th power in $\mathbb{Z}^2$. That is, $w$ is not a test element if and only if $w$ is visible in $F$.

**Proof.** Suppose first that $w$ is a test element but that $\overline{w}$ cannot be represented as an $n$-th power in $\mathbb{Z}^2$ for $n \geq 2$. Then $\gcd(w_a, w_b) = 1$. Hence there exist integers $p$ and $q$ such that $pw_a + qw_b = 1$. Consider an endomorphism $\phi : F \to F$ defined by $\phi(a) = w^p$ and $\phi(b) = w^q$. Then $\phi(w) = w$ and $\phi$ is not an automorphism of $F$ since $\phi(F)$ is cyclic. Hence, by definition, $w$ is not a test element in $F$, yielding a contradiction.

Suppose now that $\overline{w}$ is an $n$-th power in $\mathbb{Z}^2$ for some $n \geq 2$ but that $w$ is not a test element. Then by Proposition 4.1 $w$ belongs to an infinite cyclic proper retract $H$ of $F$. Since by assumption $w$ is not a proper power in $F$, it follows that $w$ generates $H$. Lemma 4.2 implies that for some free basis $(a_1, b_1)$ of $F$ we have $w = a_1c$ where $c$ belongs to the normal closure of $b_1$ in $F$. Hence when $w$ is expressed as a word in $a_1, b_1$, the exponent sum on $a_1$ in $w$ is equal to 1, which contradicts the assumption that $\overline{w}$ is an $n$-th power in the abelianization of $F$. $\Box$
Note that if \( w \in F = F(a, b) \) then \( w \) is an \( n \)-th power in \( \mathbb{Z}^2 \) for some \( n \geq 2 \) if and only if \( \gcd(w_a, w_b) > 1 \). By convention we set \( \gcd(0, 0) = \infty \).

It is well-known and easy to prove that the set of proper powers in a free group is negligible [1]:

**Proposition 4.4.** Let \( F = F(A) \) be a free group of finite rank \( k \geq 2 \) with free basis \( A = \{a_1, \ldots, a_k\} \). Let \( P \) be the set of all nontrivial elements of \( F \) that are proper powers.

Then
\[
\lim_{n \to \infty} \gamma_A(n, P) = \lim_{n \to \infty} \rho_A(n, P) = 0.
\]

and the convergence in both limits is exponentially fast.

**Proof of Theorem 5.** Since \( \zeta(2) = \frac{\pi^2}{6} \), Theorem 5 now follows directly from Theorem 3 Proposition 4.3 and Proposition 4.4. \( \square \)

5. Open Problems

As before, let \( F = F(A) \) be a free group of rank \( k \geq 2 \) with free basis \( A = \{a_1, \ldots, a_k\} \) and let \( \alpha : F \to \mathbb{Z}^k \) be the abelianization homomorphism.

**Problem 5.1.** Let \( k \geq 3 \). Is the set of test elements negligible in \( F \)? In view of Proposition 4.4 this is equivalent to asking if the union of all proper retracts of \( F \) is generic in \( F \).

The proof of Proposition 4.4 shows that a visible element in \( F \) is never a test element and therefore by Theorem 3 the asymptotic density of the set of test elements in \( F \) is at most \( 1 - \frac{1}{\zeta(k)} \). For \( k \geq 2 \) we have \( 0 < 1 - \frac{1}{\zeta(k)} < 1 \) and
\[
\lim_{k \to \infty} 1 - \frac{1}{\zeta(k)} = 0.
\]
Thus the asymptotic density of the set of test elements of \( F \) tends to zero as the rank \( k \) of \( F \) tends to infinity.

Note that every free factor of \( F \) is a retract, but the converse is not true. As mentioned in the Introduction, the union of all proper free factors is negligible in \( F \), whereas the union of all proper retracts is not since every visible element of \( F \) belongs to a proper retract.

**Problem 5.2.** For \( k \geq 2 \) find a subset \( S \subseteq \mathbb{Z}^k \) such that \( \overline{\mathcal{P}_{||.||}}(S) \neq \sigma_A(\alpha^{-1}(S)) \).

Note that if such a set \( S \) exists then it is not invariant under the action of \( SL(k, \mathbb{Z}) \) in view of Theorem A.

**Problem 5.3.** For \( w \in F \) define \( T(w) = 0 \) if \( \alpha(w) = 0 \) and define \( T(w) \) to be the greatest common divisor of the coordinates of \( \alpha(w) \) if \( \alpha(w) \neq 0 \). Let \( T'_n \) be the expected value of \( T \) over the sphere of radius \( n \) in \( F \) with respect to the uniform distribution on that sphere and let \( T_n = (T'_{n-1} + T'_n)/2 \). What can one say about the behavior of \( T_n \) as \( n \to \infty \)?

Using the results of this paper we can show that \( \lim_{n \to \infty} T_n = \infty \) for the case \( k = 2 \). It also seems plausible that for each \( k \geq 3 \) we have \( \limsup_{n \to \infty} T_n < \infty \) and heuristic considerations allow us to conjecture that in fact \( \lim_{n \to \infty} T_n = \frac{\zeta(k-1)}{\zeta(k)} \). A similar question for \( \mathbb{Z}^2 \) has been studied in detail by Diaconis and Erdős [10], who computed the precise asymptotics, as \( n \to \infty \), of the expected value for the greatest common divisor of the coordinates, computed for the uniform distribution on the \( n \times n \)-square in \( \mathbb{Z}^2 \).
Problem 5.4. Let $G$ be a torsion-free one-ended word-hyperbolic group. Is it true that the set of test elements in $G$ is generic with respect to the word-length?

Although we do not know the asymptotic density of the set of test elements in a free group of rank $k \geq 3$, one may still expect a positive answer to Problem 5.4, especially if the hyperbolic group $G$ is not just one-ended but also does not admit essential $\mathbb{Z}$-splittings. In this case the structure of endomorphisms and automorphisms of $G$ is much more restricted than in free groups.

As we have seen, the set of proper powers is negligible in free groups of rank $k \geq 2$ but has positive asymptotic density in free abelian groups of finite rank. This raises the corresponding question about free groups in other varieties. It is possible to show that if $G$ is a finitely generated nilpotent group and $t \geq 2$ then the set of $t$-th powers has positive asymptotic density in $G$.

Problem 5.5. Let $G$ be a finitely generated nonabelian free solvable group. What can be said about the asymptotic density of the set of all proper powers in $G$?
