Variance function estimation in high-dimensions

Mladen Kolar, James Sharpnack*

May 1, 2014

Abstract

We consider the high-dimensional heteroscedastic regression model, where the mean and the log variance are modeled as a linear combination of input variables. Existing literature on high-dimensional linear regression models has largely ignored non-constant error variances, even though they commonly occur in a variety of applications ranging from biostatistics to finance. In this paper we study a class of non-convex penalized pseudolikelihood estimators for both the mean and variance parameters. We show that the Heteroscedastic Iterative Penalized Pseudolikelihood Optimizer (HIPPO) achieves the oracle property, that is, we prove that the rates of convergence are the same as if the true model was known. We demonstrate numerical properties of the procedure on a simulation study and real world data.

1 Introduction

High-dimensional regression models have been studied extensively in both machine learning and statistical literature. Statistical inference in high-dimensions, where the sample size $n$ is smaller than the ambient dimension $p$, is impossible without assumptions. As the concept of parsimony is important in many scientific domains, most of the research in the area of high-dimensional statistical inference is done under the assumption that the underlying model is sparse, in the sense that the number of relevant parameters is much smaller than $p$, or that it can be well approximated by a sparse model.

Penalization of the empirical loss by the $\ell_1$ norm has become a popular tool for obtaining sparse models and huge amount of literature exists on theoretical properties of estimation procedures [see, e.g., Zhao and Yu, 2006, Wainwright, 2009, Zhang, 2009, Zhang and Huang, 2008 and references therein] and on efficient algorithms that numerically find estimates [see Bach et al., 2011 for an extensive literature review]. Due to limitations of the $\ell_1$ norm penalization, high-dimensional inference methods based on the class of concave penalties have been proposed that have better theoretical and numerical properties [see, e.g., Fan and Li, 2001, Fan and Lv, 2009, Lv and Fan, 2009, Zhang and Zhang, 2011].

*Authors listed alphabetically.
In all of the above cited work, the main focus is on model selection and mean parameter estimation. Only few papers deal with estimation of the variance in high-dimensions [Sun and Zhang, 2011, Fan et al., 2012] although it is a fundamental problem in statistics. Variance appears in the confidence bounds on estimated regression coefficients and is important for variable selection as it appears in Akaike’s information criterion (AIC) and the Bayesian information criterion (BIC). Furthermore, it provides confidence on the predictive performance of a forecaster.

In applied regression it is often the case that the error variance is non-constant. Although the assumption of a constant variance can sometimes be achieved by transforming the dependent variable, e.g., by using a Box-Cox transformation, in many cases transformation does not produce a constant error variance [Carroll and Ruppert, 1988]. Another approach is to ignore the heterogeneous variance and use standard estimation techniques, but such estimators are less efficient. Aside from its use in reweighting schemes, estimating variance is important because the resulting prediction intervals become more accurate and it is often important to explore which input variables drive the variance. In this paper, we will model the variance directly as a parametric function of the explanatory variables.

Heteroscedastic regression models are used in a variety of fields ranging from biostatistics to econometrics, finance and quality control in manufacturing. In this paper, we study penalized estimation in high-dimensional heteroscedastic linear regression models, where the mean and the log variance are modeled as a linear combination of explanatory variables. Modeling the log variance as a linear combination of the explanatory variables is a common choice as it guarantees positivity and is also capable of capturing variance that may vary over several orders of magnitudes [Carroll and Ruppert, 1988, Harvey, 1976]. Main contributions of this paper are as follows. First, we propose HIPPO (Heteroscedastic Iterative Penalized Pseudolikelihood Optimizer) for estimation of both the mean and variance parameters. Second, we establish the oracle property (in the sense of Fan and Li, 2009) for the estimated mean and variance parameters. Finally, we demonstrate numerical properties of the proposed procedure on a simulation study, where it is shown that HIPPO outperforms other methods, and analyze a real data set.

1.1 Problem Setup and Notation
Consider the usual heteroscedastic linear model,

\[ y_i = x_i' \beta + \sigma(x_i, \theta) \epsilon_i, \quad i = 1, \ldots, n, \]

where \( X = (x_1, \ldots, x_n)' = (X_1, \ldots, X_p) \) is an \( n \times p \) matrix of predictors with i.i.d. rows \( x_1, \ldots, x_n \), \( y = (y_1, \ldots, y_n) \) is an \( n \)-vector of responses, the vectors \( \beta \in \mathbb{R}^p \) and \( \theta \in \mathbb{R}^p \) are \( p \)-vectors of mean and variance parameters, respectively, and \( \epsilon = (\epsilon_1, \ldots, \epsilon_n) \) is an \( n \)-vector of i.i.d. random noise with mean 0 and variance 1. We assume that the noise \( \epsilon \) is independent of the predictors \( X \). The function
\( \sigma(x, \theta) \) has a known parametric form and, for simplicity of presentation, we assume that it takes a particular form \( \sigma(x, \theta) = \exp(x' \theta/2) \).

Throughout the paper we use \([n]\) to denote the set \( \{1, \ldots, n\} \). For any index set \( S \subseteq [p] \), we denote \( \beta_S \) to be the subvector containing the components of the vector \( \beta \) indexed by the set \( S \), and \( X_S \) denotes the submatrix containing the columns of \( X \) indexed by \( S \). For a vector \( a \in \mathbb{R}^n \), we denote \( \text{supp}(a) = \{j : a_j \neq 0\} \) the support set, \( \|a\|_q, q \in (0, \infty) \), the \( \ell_q \)-norm defined as \( \|a\|_q = (\sum_{i \in [n]} a_i^q)^{1/q} \) with the usual extensions for \( q \in \{0, \infty\} \), that is, \( \|a\|_0 = |\text{supp}(a)| \) and \( \|a\|_\infty = \max_{i \in [n]} |a_i| \). For notational simplicity, we denote \( \| \cdot \| = \| \cdot \|_2 \) the \( \ell_2 \) norm. For a matrix \( A \in \mathbb{R}^{n \times p} \) we denote \( \|A\|_2 \) the operator norm, \( \|A\|_F \) the Frobenius norm, and \( \lambda_{\min}(A) \) and \( \lambda_{\max}(A) \) denote the smallest and largest eigenvalue respectively.

Under the model in (1), we are interested in estimating both \( \beta \) and \( \theta \). In high-dimensions, when \( p \gg n \), it is common to assume that the support \( \beta \) is small, that is, \( S = \text{supp}(\beta) \) and \( |S| \ll n \). Similarly, we assume that the support \( T = \text{supp}(\theta) \) is small.

### 1.2 Related Work

Consider the model (1) with constant variance, i.e., \( \sigma(x, \theta) \equiv \sigma_0 \). Most of the existing high-dimensional literature is focused on estimation of the mean parameter \( \beta \) in this homoscedastic regression model. Under a variety of assumptions and regularity conditions, any penalized estimation procedure mentioned in introduction can, in theory, select the correct sparse model with probability tending to 1. Literature on variance estimation is not as developed. Fan et al. [2012] proposed a two step procedure for estimation of the unknown variance \( \sigma_0 \), while Sun and Zhang [2011] proposed an estimation procedure that jointly estimates the model and the variance.

Problem of estimation in the heteroscedastic linear regression models have been studied extensively in the classical setting with \( p \) fixed, however, the problem of estimation under the model (1) when \( p \gg n \) has not been adequately studied. Jia et al. [2010] assume that \( \sigma(x, \theta) = |x' \beta| \) and show that Lasso is sign consistent for the mean parameter \( \beta \) under certain conditions. Their study shows limitations of lasso, for which many highly scalable solvers exist. However, no new methodology is developed, as the authors acknowledge that the log-likelihood function is highly non-convex. Dette and Wagener [2011] study the adaptive lasso under the model in (1). Under certain regularity conditions, they show that the adaptive lasso is consistent, with suboptimal asymptotic variance. However, the weighted adaptive lasso is both consistent and achieves optimal asymptotic variance, under the assumption that the variance function is consistently estimated. However, they do not discuss how to obtain an estimator of the variance function in a principled way and resort to an ad-hoc fitting of the residuals. Dave et al. [2011] develop HHR procedure that optimizes the penalized log-likelihood under (1) with the \( \ell_1 \)-norm penalty on both the mean and variance parameters. As the objective is not convex, HHR estimates \( \beta \) with \( \theta \) fixed and then estimates \( \theta \) with \( \beta \) fixed, until convergence. Since the
objective is biconvex, HHR converges to a stationary point. However, no theory is provided for the final estimates.

2 Methodology

In this paper, we propose HIPPO (Heteroscedastic Iterative Penalized Pseudo-likelihood Optimizer) for estimating $\beta$ and $\theta$ under model $(\Pi)$.

In the first step, HIPPO finds the penalized pseudolikelihood maximizer of $\beta$ by solving the following objective

$$
\hat{\beta} = \arg \min_{\beta \in \mathbb{R}^p} ||y - X\beta||^2 + 2n \sum_{j \in [p]} \rho_{\lambda_S}(|\beta_j|),
$$

(2)

where $\rho_{\lambda_S}$ is the penalty function and the tuning parameter $\lambda_S$ controls the sparsity of the solution $\hat{\beta}$.

In the second step, HIPPO forms the penalized pseudolikelihood estimate for $\theta$ by solving

$$
\hat{\theta} = \arg \min_{\theta \in \mathbb{R}^p} \sum_{i \in [n]} x_i'\theta + \sum_{i \in [n]} \hat{\eta}_i^2 \exp(-x_i'\theta) + 4n \sum_{j \in [p]} \rho_{\lambda_T}(|\theta_j|)
$$

(3)

where $\hat{\eta} = y - X\hat{\beta}$ is the vector of residuals.

Finally, HIPPO computes the reweighted estimator of the mean by solving

$$
\hat{\beta}_w = \arg \min_{\beta \in \mathbb{R}^p} \sum_{i \in [n]} \frac{(y_i - x_i'\beta)^2}{\hat{\sigma}_i} + 2n \sum_{j \in [p]} \rho_{\lambda_S}(|\beta_j|)
$$

(4)

where $\hat{\sigma}_i = \exp(x_i'\hat{\theta}/2)$ are the weights.

In classical literature, estimation under heteroscedastic models is achieved by employing a pseudolikelihood objective. The pseudolikelihood maximization principle prescribes the scientist to maximize a surrogate likelihood, i.e., one that is believed to be similar to the likelihood with the true unknown fixed variances (or means alternatively). In classical theory, central limit theorems are derived for many pseudo-maximum likelihood (PML) estimators using generalized estimating equations [Ziegler 2011]. HIPPO fits neatly into the pseudolikelihood framework because the first step is a regularized PML where only the mean structure needs to be correctly specified. The second step and third steps may be similarly cast as PML estimators. Indeed, all our theoretical results are due to the fact that in each step we are optimizing a pseudolikelihood that is similar to the true unknown likelihoods (with alternating free parameters). Moreover, it is known that if the surrogate variances in the mean PML are more similar to the true variances then the resulting estimates will be more asymptotically efficient. With this in mind, we recommend a third reweighting procedure with the variance estimates from the second step.
Fan and Li [2001] advocate usage of penalty functions that result in estimates satisfying three properties: unbiasedness, sparsity and continuity. A reasonable estimator should correctly identify the support of the true parameter with probability converging to one. Furthermore, on this support, the estimated coefficients should have the same asymptotic distribution as if an estimator that knew the true support was used. Such an estimator satisfies the oracle property. A number of concave penalties result in estimates that satisfy this property: the SCAD penalty [Fan and Li, 2001], the MCP penalty [Zhang, 2010] and a class of folded concave penalties [Lv and Fan, 2009]. For concreteness, we choose to use the SCAD penalty, which is defined by its derivative

\[ \rho_\lambda'(t) = \lambda \left[ I\{t \leq \lambda\} + \frac{(a\lambda - t)_+}{(a-1)\lambda} I\{t > \lambda\} \right], \]

where often \( a = 3.7 \) is used. Note that estimates produced by the \( \ell_1 \)-norm penalty are biased, and hence this penalty does not achieve oracle property.

HIPPO is related to the iterative HHR algorithm of [Dave et al., 2011]. In particular, the first two iterations of HHR are equivalent to HIPPO with the SCAD penalty replaced with the \( \ell_1 \) norm penalty. In practice, one can continue iterating between solving (3) and (4), however, establishing theoretical properties for those iterates is a non-trivial task. From our numerical studies, we observe that HIPPO performs well when stopped after the first two iterations.

2.1 Tuning Parameter Selection

As described in the previous section, HIPPO requires selection of the tuning parameters \( \lambda_S \) and \( \lambda_T \), which balance the complexity of the estimated model and the fit to data. A common approach is to form a grid of candidate values for the tuning parameters \( \lambda_S \) and \( \lambda_T \) and chose those that minimize the AIC or BIC criterion

\[
\text{AIC}(\lambda_S, \lambda_T) = \sum_{i \in [n]} \ell(y_i, x_i; \hat{\beta}, \hat{\theta}) + 2\hat{d}f, \\
\text{BIC}(\lambda_S, \lambda_T) = \sum_{i \in [n]} \ell(y_i, x_i; \hat{\beta}, \hat{\theta}) + \hat{d}f \log n
\]

where, up to constants,

\[ \ell(y, x; \beta, \theta) = x'\theta + (y - x'\beta)^2 \exp(-x'\theta) \]

is the negative log-likelihood and

\[ \hat{d}f = |\text{supp}(\hat{\beta})| + |\text{supp}(\hat{\theta})| \]

is the estimated degrees of freedom. In Section 4 we compare performance of the AIC and the BIC for HIPPO in a simulation study.
2.2 Optimization Procedure

In this section, we describe numerical procedures used to solve optimization problems in (2), (3) and (4). Our procedures are based on the local linear approximation for the SCAD penalty developed in Zou and Li [2008], which gives:

\[ \rho(\lambda | \beta_j |) \approx \rho(\lambda | \beta_j^{(k)} |) + \rho'(\lambda | \beta_j^{(k)} |)(|\beta_j| - |\beta_j^{(k)}|), \]

for \( \beta_j \approx \beta_j^{(k)} \).

This approximation allows us to substitute the SCAD penalty \( \sum_{j \in [p]} \rho(\lambda | \beta_j |) \) in (2), (3) and (4) with \( \sum_{j \in [p]} \rho'(\lambda | \hat{\beta}_j^{(k)} |)|\beta_j| \), (8) and iteratively solve each objective until convergence of \( \{\hat{\beta}_j^{(k)}\}_k \). We set the initial estimates \( \hat{\beta}^{(0)} \) and \( \hat{\theta}^{(0)} \) to be the solutions of the \( \ell_1 \)-norm penalized problems. The convergence of these iterative approximations follows from the convergence of the MM (minorize-maximize) algorithms [Zou and Li, 2008].

With the approximation of the SCAD penalty given in (8), we can solve (2) and (4) using standard lasso solvers, e.g., we use the proximal method of Beck and Teboulle [2009]. The objective in (3) is minimized using a coordinate descent algorithm, which is detailed in [Daye et al., 2011].

3 Theoretical Properties of HIPPO

In this section, we present theoretical properties of HIPPO. In particular, we show that HIPPO achieves the oracle property for estimating the mean and variance under the model (1). All the proofs are deferred to Appendix.

We will analyze HIPPO under the following assumptions, which are standard in the literature on high-dimensional statistical learning [see, e.g. Fan et al., 2012].

**Assumption 1.** The matrix \( X = (x_1, \ldots, x_n)' \in \mathbb{R}^{n \times p} \) has independent rows that satisfy \( x_i = \Sigma^{1/2} z_i \), where \( \{z_i\}_i \) are i.i.d. subgaussian random variables with \( \mathbb{E} z_i = 0 \), \( \mathbb{E} z_i z_i' = I \) and parameter \( K \) (see Appendix for more details on subgaussian random variables). Furthermore, there exist two constants \( C_{\min}, C_{\max} > 0 \) such that

\[ 0 < C_{\min} \leq \Lambda_{\min}(\Sigma) \leq \Lambda_{\max}(\Sigma) \leq C_{\max} < \infty. \]

**Assumption 2.** The errors \( \epsilon_1, \ldots, \epsilon_n \) are i.i.d. subgaussian with zero mean and parameter 1.

**Assumption 3.** There are two constants \( \bar{\beta} \) and \( \bar{\theta} \) such that \( ||\beta|| \leq \bar{\beta} < \infty \) and \( ||\theta|| \leq \bar{\theta} < \infty \).

**Assumption 4.** \( |S| = C_S n^{\alpha_S} \) and \( |T| = C_T n^{\alpha_T} \) for some \( \alpha_S \in (0, 1) \) and \( \alpha_T \in (0, 1/3) \) and constants \( C_S, C_T > 0 \).

The following assumption will be needed for showing the consistency of the weighted estimator \( \beta_w \) in (4).
Assumption 5. Define

\[ D_{SS} = n^{-1}X'_S \text{diag}(\exp(-X\theta))X_S. \]

There exist constants \(0 \leq D_{\min}, D_{\max} \leq \infty\) such that

\[ \lim_{n \to \infty} \mathbb{P}[\Lambda_{\max}(D_{SS}) \leq D_{\max}] = 1, \quad \text{and} \]
\[ \lim_{n \to \infty} \mathbb{P}[\Lambda_{\min}(D_{SS}) \geq D_{\min}] = 1. \]

Furthermore, we have that

\[ \lim_{n \to \infty} \|D_{SS} - \mathbb{E}D_{SS}\|_2 = o_P(1). \]

With these assumption, we state our first result, regarding the estimator \(\hat{\beta}\) in \(\text{(2)}\).

**Theorem 1.** Suppose that the assumptions (1)-(4) are satisfied. Furthermore, assume that \(\lambda_S \geq c_1 \sqrt{\log(p) \exp(\sqrt{c_2 \log(n)})/n}, \min_{j \in [S]} |\beta_j| \gg \lambda_S \gg c_3 \sqrt{\log(s) \exp(\sqrt{c_2 \log(n)})/n}\) and \(\log(p) = \mathcal{O}(n^{\alpha_0})\) for some \(\alpha_0 \in (0,1)\). Then there is a strict local minimizer \(\hat{\beta} = (\hat{\beta}'_S, 0'_S)'\) of \(\text{(2)}\) that satisfies

\[ ||\hat{\beta}_S - \beta_S||_\infty \leq c_3 \sqrt{\log(s) \exp(\sqrt{c_2 \log(n)})/n} \]

for some positive constants \(c_1, c_2, c_3\) and sufficiently large \(n\).

In addition, if we suppose that assumption (5) is satisfied, then for any fixed \(a \in \mathbb{R}^s\) with \(\|a\|_2 = 1\) the following weak convergence holds

\[ \frac{\sqrt{n}}{\zeta} a'(\hat{\beta}_S - \beta_S) \xrightarrow{D} N(0,1) \]

where \(\zeta^2 = a' \Sigma_{SS}^{-1} \mathbb{E}D_{SS} \Sigma_{SS}^{-1} a\).

The first result stated in Theorem 1 established that \(\hat{\beta}\) achieves the weak oracle property in the sense of Lv and Fan [2009]. The extra term \(\exp(\sqrt{\log n})\) is subpolynomial in \(n\) and appears in the bound due to the heteroscedastic nature of the errors. The second result establishes the strong oracle property of the estimator \(\hat{\beta}\) in the sense of Fan and Lv [2009], that is, we establish the asymptotic normality on the true support \(S\). The asymptotic normality shows that \(\hat{\beta}_S\) has the same asymptotic variance as the ordinary least squares (OLS) estimator on the true support. However, in the case of a heteroscedastic model the OLS estimator is dominated by the generalized least squares estimator. Later in this section, we will demonstrate that \(\hat{\beta}_w\) has better asymptotic variance. Note that \(\hat{\beta}\) correctly selects the mean model and estimates the parameters at the correct rate. From the upper and lower bounds on \(\lambda_S\), we see how the rate at which \(p\) can grow and the minimum coefficient size are related. Larger the
ambient dimension $p$ gets, larger the size of $\lambda_S$, which lower bounds the size of the minimum coefficient.

Our next result establishes correct model selection for the variance parameter $\theta$.

**Theorem 2.** Suppose that assumptions (1)-(5) are satisfied. Suppose further that $\lambda_T \geq n^{\alpha_T - 1/2} \log(p) \log(n)$ and $\min_{j \in [T]} |\theta_j| \geq \lambda_T$. Then there is a strict local minimizer $\hat{\theta} = (\hat{\theta}_T', 0_{T-c}')'$ with the strong oracle property,

$$||n^{(1-\alpha_T)/2}(\hat{\theta} - \theta)|| = O_p(1)$$

Moreover, for any fixed $a \in \mathbb{R}^t$ with $||a||_2 = 1$ the following weak convergence holds

$$\sqrt{n}a'(\hat{\theta}_T - \theta_T) \xrightarrow{D} N(0, 1)$$

where $\zeta^2 = a'(\Sigma_T)^{-1}a$.

With the convergence result of $\hat{\theta}$ we can prove consistency and asymptotic normality of the weighted estimator $\hat{\beta}_w$ in (4).

**Theorem 3.** Suppose that the assumptions (1)-(5) are satisfied and that there exists an estimator $\hat{\theta}$ satisfying $||\hat{\theta} - \theta||_2 = O(r_n)$, for a sequence $r_n \to 0$ and supp($\hat{\theta}$) = supp($\theta$). Furthermore, assume that $\lambda_S \geq c_1 \sqrt{\log(p) \exp(\sqrt{c_2 \log(n)})/n}$, $\min_{j \in [S]} |\beta_j| \gg \lambda_S \gg c_2 r_n \exp(\sqrt{c_1 \log(n)}) \log(n) \log(p) = O(n^{a_0})$ for some $a_0 \in (0, 1)$. Then there is a strict local minimizer $\hat{\beta}_w = (\hat{\beta}_{w,S}, 0_{Sc})'$ of (4) that satisfies

$$||\hat{\beta}_{w,S} - \beta_S||_\infty \leq c_3 r_n \exp(\sqrt{c_2 \log(n)}) \log(n)$$

(12)

for some positive constants $c_1, c_2,$ and $c_3$ and sufficiently large $n$.

Furthermore, for any fixed $a \in \mathbb{R}^t$ with $||a||_2 = 1$ the following weak convergence holds

$$\sqrt{n}a'(\hat{\beta}_{w,S} - \beta_S) \xrightarrow{D} N(0, 1)$$

where $\zeta_{w}^2 = a'(E_{SS}+)^{-1}a$.

Theorem 3 establishes convergence of the weighted estimator $\hat{\beta}_W$ in (4) and the model selection consistency. The rate of convergence depends on the rate of convergence of the variance estimator, $r_n$. From Theorem 2 we show the parametric rate of convergence for $\hat{\theta}_S$. The second result of Theorem 3 states that the weighted estimator $\hat{\beta}_{w,S}$ is asymptotically normal, with the same asymptotic variance as the generalized least squares estimator which knows the true model and variance function $\sigma(x, \theta)$. 

\[ ||\theta - \hat{\theta}||_2 \quad \text{Pre}_\theta \quad \text{Rec}_\theta \]

| \(\rho = 0\) |            |            |
|----------|------------|------------|
| HHR-AIC  | 0.59(0.13) | 0.4(0.17)  |
| HIPPO-AIC| 0.26(0.15) | 0.6(0.22)  |
| HHR-BIC  | 0.59(0.13) | 0.39(0.16) |
| HIPPO-BIC| 0.26(0.15) | 0.59(0.22) |

| HIPPO-AIC      | 0.38(0.22) | 0.69(0.25) |
| HHR-BIC        | 0.32(0.12) | 0.68(0.21) |
| HIPPO-BIC      | 0.38(0.22) | 0.69(0.25) |

Table 1: Mean (sd) performance of HHR and HIPPO under the model in Example 1 (averaged over 100 independent runs). The mean parameter \(\beta\) is assumed to be known.

4 Monte-Carlo Simulations

In this section, we conduct two small scale simulation studies to demonstrate finite sample performance of HIPPO. We compare it to the HHR procedure [Dave et al., 2011].

Convergence of the parameters is measured in the \(\ell_2\) norm, \(||\hat{\beta} - \beta||\) and \(||\hat{\theta} - \theta||\). We measure the identification of the support of \(\beta\) and \(\theta\) using precision and recall. Let \(\hat{S}\) denote the estimated set of non-zero coefficients of \(S\), then the precision is calculated as \(\text{Pre}_\beta := |\hat{S} \cap S|/|\hat{S}|\) and the recall as \(\text{Rec}_\beta := |\hat{S} \cap S|/|S|\). Similarly, we can define precision and recall for the variance coefficients. We report results averaged over 100 independent runs.

4.1 Example 1

Assume that the data is generated iid from the following model \(Y = \sigma(X)\epsilon\) where \(\epsilon\) follows a standard normal distribution and the logarithm of the variance is given by

\[ \log \sigma(X)^2 = X_1 + X_2 + X_3. \]

The covariates associated with the variance are jointly normal with equal correlation \(\rho\), and marginally \(\mathcal{N}(0,1)\). The remaining covariates, \(X_4, \ldots, X_p\) are iid random variables following the standard Normal distribution and are independent from \((X_1, X_2, X_3)\). We set \((n, p) = (200, 2000)\) and use \(\rho = 0\) and \(\rho = 0.5\). Estimation procedures know that \(\beta = 0\) and we only estimate the variance parameter \(\theta\). This example is provided to illustrate performance of the penalized pseudolikelihood estimators in an idealized situation. When the mean parameter needs to be estimated as well, we expect the performance of the procedures
only to get worse. Since the mean is known, both HHR and HIPPO only solve the optimization procedure in (3), HHR with the $\ell_1$-norm penalty and HIPPO with the SCAD penalty, without iterating between (4) and (3). Table 1 summarizes the results. Under this toy model, we observe that HIPPO performs better than HHR when the correlation between the relevant predictors is $\rho = 0$. However, we do not observe the difference between the two procedures when $\rho = 0.5$. The difference between the AIC and BIC is already visible in this example when $\rho = 0$. The AIC tends to pick more complex models, while the BIC is more conservative and selects a model with fewer variables.

### 4.2 Example 2

The following non-trivial model is borrowed from [Dave et al., 2011]. The response variable $Y$ satisfies

$$Y = \beta_0 + \sum_{j \in [p]} X_j \beta_j + \exp(\theta_0 + \sum_{j \in [p]} X_j \theta_j) \epsilon$$
with \( p = 600, \beta_0 = 2, \theta_0 = 1, \)

\[
\beta_{[12]} = (3, 3, 1.5, 1.5, 0, 0, 0, 2, 2, 2)',
\]

\[
\theta_{[15]} = (1, 1, 0, 0, 0.5, 0.5, 0.5, 0, 0, 0.75, 0.75, 0.75)',
\]

and the remainder of the coefficients are 0. The covariates are jointly Normal with \( \text{cov}(X_i, X_j) = 0.5^{|i-j|} \) and the error \( \epsilon \) follows the standard Normal distribution. This is a more realistic model than the one described in the previous example. We set \( p = 600 \) and the number of samples \( n = 200 \) and \( n = 400 \).

Table 2 summarizes results of the simulation. We observe that HIPPO consistently outperforms HHR in all scenarios. Again, a general observation is that the AIC selects more complex models although the difference is less pronounced when the sample size \( n = 400 \). Furthermore, we note that the estimation error significantly reduces after the first iteration, which demonstrates final sample benefits of estimating the variance. Recall that Theorem 1 proves that the estimate \( \hat{\beta} \) consistently estimates the true parameter \( \beta \). However, it is important to estimate the variance parameter \( \theta \) well, both in theory (see Theorem 3) and practice.

## 5 Real Data Application

Forecasting the gross domestic product (GDP) of a country based on macroeconomic indicators is of significant interest to the economic community. We obtain both the country GDP figures (specifically we use the GDP per capita using current prices in units of a ‘national currency’) and macroeconomic variables from the International Monetary Fund’s World Economic Outlook (WEO) database. The WEO database contains records for macroeconomic variables from 1980 to 2016 (with forecasts).

To form our response variable, \( y_{i,t} \), we form log-returns of the GDP for each country \( i \) for each time point \( t \) after records began and before the forecasting commenced (each country had a different year at which forecasting began). After removing missing values, we obtained 31 variables that can be grouped into a few broad categories: balance of payments, government finance and debt, inflation, and demographics. We apply various transformations, including lagging and logarithms forming the vectors \( x_{i,t} \). We fit the heteroscedastic AR(1) model with HIPPO.

\[
y_{i,t} = x_{i,t-1}'\beta + \exp(x_{i,t-1}'\theta)\epsilon_{i,t}
\]

In order to initially assess the heteroscedasticity of the data, we form the LASSO estimator with the LARS package in R selecting with BIC. It is common practice when diagnosing heteroscedasticity to plot the studentized residuals against the fitted values. We bin the bulk of the samples into three groups by fitted values, and observe the box-plot of each bin by residuals (Figure 2). It is apparent that there is a difference of variances between these bins, which is corroborated by performing a F-test of equal variances across the second and
Table 3: Performance of HIPPO and HHR on WEO data averaged over 10 folds.

|            | HIPPO  | HHR  |
|------------|--------|------|
| MSE        | 0.0089 | 0.0091 |
| $-\ell(y, X; \hat{\beta}, \hat{\theta})$ | 0.4953 | 0.6783 |
| $|\hat{S}|$ | 5.4   | 8.9  |
| $|\hat{T}|$ | 8.2   | 5.1  |

third bins (p-value of $4 \times 10^{-6}$). We further observe differences of variance between country GDP log returns. We analyzed the distribution of responses separated by countries: Canada, Finland, Greece and Italy. The p-value from the F-test for equality of variances between the countries Canada and Greece is 0.008, which is below even the pairwise Bonferroni correction of 0.0083 at 0.05 significance level. This demonstrates heteroscedasticity in the WEO dataset, and we are justified in fitting non-constant variance.

We compare the results from HIPPO and HHR when applied to the WEO data set. The tuning parameters were selected with BIC over a grid for $\lambda_S$ and $\lambda_T$. The metrics used to compare the algorithms are mean square error (MSE) defined by $\frac{1}{n} \sum_i (y_{i,t} - \hat{y}_{i,t})^2$, the partial prediction score defined as the average of the negative log likelihoods, and the number of selected mean parameters and variance parameters. We perform 10-fold cross validation to obtain unbiased estimates of these metrics. In Table 3 we observe that HIPPO outperforms HHR in terms of MSE and partial prediction score.

6 Discussion

We have addressed the problem of statistical inference in high-dimensional linear regression models with heteroscedastic errors. Heteroscedastic errors arise in many applications and industrial settings, including biostatistics, finance and quality control in manufacturing. We have proposed HIPPO for model selection and estimation of both the mean and variance parameters under a heteroscedastic model. HIPPO can be deployed naturally into an existing data analysis work-flow. Specifically, as a first step, a statistician performs penalized estimation of the mean parameters and then, as a second step, tests for heteroscedasticity by running the second step of HIPPO. If heteroscedasticity is discovered, HIPPO can then be used to solve penalized generalized least squares objective. Furthermore, HIPPO is well motivated from the penalized pseudolikelihood maximization perspective and achieves the oracle property in high-dimensional problems.

Throughout the paper, we focus on a specific parametric form of the variance function for simplicity of presentation. Our method can be extended to any parametric form, however, the assumptions will become more cumbersome and the particular numerical procedure would change. It is of interest to develop
general unified framework for estimation of arbitrary parametric form of the variance function. Another open research direction includes non-parametric estimation of the variance function in high-dimensions, which could be achieved with sparse additive models [see Ravikumar et al., 2009].

7 Appendix

In the appendix, we collect some well known results and provide proofs for the results in the main text.

For readers convenience, we summarize the notation again. We use \([n]\) to denote the set \(\{1, \ldots, n\}\). For any index set \(S \subseteq [p]\), we denote \(\beta_S\) to be the subvector containing the components of the vector \(\beta\) indexed by the set \(S\), and \(X_S\) denotes the submatrix containing the columns of \(X\) indexed by \(S\). For a vector \(a \in \mathbb{R}^n\), we denote \(\text{supp}(a) = \{ j : a_j \neq 0 \}\) the support set, \(\|a\|_q\), \(q \in (0, \infty)\), the \(\ell_q\)-norm defined as \(\|a\|_q = (\sum_{i \in [n]} a_i^q)^{1/q}\) with the usual extensions for \(q \in \{0, \infty\}\), that is, \(\|a\|_0 = \text{supp}(a)\) and \(\|a\|_\infty = \max_{i \in [n]} |a_i|\).

For notational simplicity, we denote \(|| \cdot || = || \cdot ||_2\) the \(\ell_2\) norm. The unit sphere of \(\ell_2^p\) is denoted by \(S^{n-1}\). The canonical bases of \(\ell_2^p\) we denote by \(e_1, \ldots, e_n\). For a matrix \(A \in \mathbb{R}^{n \times p}\) we denote \(||A||_2 = \sup\{ ||Ax|| : ||x|| = 1 \}\) the operator norm and \(||A||_F = \sqrt{\sum_{i \in [n]} \sum_{j \in [p]} a_{ij}^2}\) the Frobenius norm. For a symmetric matrix \(A \in \mathbb{R}^{n \times n}\), we use \(\Lambda_{\min}(A)\) to denote \(\Lambda_{\max}(A)\) the smallest and largest eigenvalue respectively.

7.1 Subgaussian random variables

In this section, we define subgaussian random variables and state a few well known properties.

We denote \(||X||_{L_p}\) the \(L_p\) norm of a random variable \(X\), i.e., \(||X||_{L_p} = (EE|X|^p)^{1/p}\). Define \(\Psi_\alpha\) the Orlitz function \(\Psi_\alpha(x) = \exp(|x|^\alpha) - 1\), \(\alpha \geq 1\). Using the Orlitz function, we can define the Orlitz space of real valued random variables, \(L_{\Psi_2}\), equipped with the norm

\[
||X||_{\Psi_2} = \inf\{c > 0 : \mathbb{E}\exp(|X/c|^\alpha) \leq 2\}.
\]

We will focus on the particular choice of \(\alpha = 2\). Define \(B_{\Psi_2}(\gamma)\) the set of real-valued symmetric random variables satisfying

\[
1 \leq ||X||_{L_2} \quad \text{and} \quad ||x||_{\Psi_2} \leq \gamma.
\]

(14)

For \(X \in B_{\Psi_2}(\gamma)\) we have a good control of the tail probability

\[
P[X \geq t] \leq \exp(-t^2/\gamma^2),
\]

(15)

which can be obtained using the Markov inequality

\[
2P[X \geq t] \leq P[|X| \geq t] \leq \frac{\mathbb{E}\exp(X^2/\gamma^2)}{\exp(t^2/\gamma^2)} \leq 2 \exp(-t^2/\gamma^2)
\]

since \(X\) is symmetric and \(\mathbb{E}\exp(X^2/\gamma^2) \leq 2\).

The space \(L_{\Psi_2}\) is the set of subgaussian random variables. A real-valued random variable \(X\) is called subgaussian with parameter \(\nu\), \(\nu > 0\), if

\[
\mathbb{E}\exp(tX) \leq \exp(\nu^2 t^2/2), \quad \text{for all} \ t > 0.
\]

(16)
It follows from this bound on the moment generating function that the following bound on the tail probability holds

$$P[X \geq t] \leq \exp(-t^2/(2\nu^2)) \text{ for any } t \geq 0. \quad (17)$$

We also have that $X \in B_{\Psi_2}(\mu)$ is subgaussian with parameter $\sqrt{2}\mu$ by direct calculation.

The following few facts are useful.

**Lemma 4.** Let $\gamma_i \geq 1$ and $X_i \in B_{\Psi_2}(\gamma_i)$, $i = 1, \ldots, n$, be independent variables, then for any $a_1, \ldots, a_n \in \mathbb{R}$, $\sum_{i \in [n]} a_i X_i$ is subgaussian with parameter $\sqrt{2} \sum_{i \in [n]} \gamma_i^2 a_i^2$.

**Proof.** For any $t > 0$, we have

$$E \exp(t \sum_{i \in [n]} a_i X_i) = \prod_{i \in [n]} E \exp(t a_i X_i) \leq \prod_{i \in [n]} \exp(t^2 a_i^2 \gamma_i^2) = \exp(t^2 \sum_{i \in [n]} a_i^2 \gamma_i^2).$$

The claim follows from (16). $\square$

**Lemma 5.** Let $\gamma \geq 1$ and $X_i \in B_{\Psi_2}(\gamma)$, $i = 1, \ldots, n$, be independent variables, then for any $u \geq 0$,

$$P\left[\sum_{i \in [n]} X_i^2 \geq u^2 n\right] \leq \exp(n(\log(2) - (u/\gamma)^2)). \quad (18)$$

**Proof.** Using Markov inequality we have,

$$P\left[\sum_{i \in [n]} X_i^2 \geq u^2 n\right] \leq \exp(-\gamma^{-2} u^2 n) E \exp(\gamma^{-2} \sum_{i \in [n]} X_i^2) \leq 2^n \exp(-\gamma^{-2} u^2 n),$$

which concludes the proof. $\square$

The notion of subgaussian random variable can be easily extended to vector random variables. Let $Z \in \mathbb{R}^p$ be random variable satisfying $E Z = 0$, $E ZZ' = I_p$. The random variable $Z$ is subgaussian with parameter $\nu$ if it satisfies

$$\sup_{w \in S^{p-1}} ||\langle z, w \rangle||_{\Psi_2} \leq \nu. \quad (19)$$

Let $X = \Sigma^{1/2} Z$ where $\Sigma \in \mathbb{R}^{p \times p}$ positive definite matrix and $\Sigma^{1/2}$ the symmetric matrix square root. The following result is standard in multivariate statistics [Anderson, 2003].

**Lemma 6.** Let $S \subset [p]$ and $j \in [p], j \notin S$. Then

$$X_j = (X_S, (\Sigma_{SS})^{-1} \Sigma_{Sj}) + E_j \quad (20)$$

and $E_j$ is uncorrelated with $X_S$. 

17
The following lemma shows that $E_j$ is subgaussian.

**Lemma 7.** The random variable $E_j$ defined in (20) is subgaussian with parameter $K \sqrt{2 \Sigma_{j|S}}$, where $\Sigma_{j|S} = \Sigma_{jj} - \Sigma_{jS}(\Sigma_{SS})^{-1} \Sigma_{Sj}$.

*Proof.* From the definition of $X$ we have that $X_j = \Sigma_{j} \cdot 1/2 Z$ and $X_S = \Sigma_{S}^{1/2} Z$.

With this, we have

$$E_j = Z' (\Sigma_j^{1/2} - \Sigma_S (\Sigma_{SS})^{-1} \Sigma_{Sj})$$

and

$$||E_j||_{\psi_2} \leq ||\Sigma_j^{1/2} - \Sigma_S^{1/2} (\Sigma_{SS})^{-1} \Sigma_{Sj}||_2 ||Z||_{\psi_2}$$

$$\leq K \sqrt{\Sigma_{jj} - \Sigma_{jS}(\Sigma_{SS})^{-1} \Sigma_{Sj}}$$

$$= K \sqrt{\Sigma_{j|S}}.$$

This concludes the proof. \(\square\)

Next, we present a few results on spectral norms of random matrices obtained as sums of random subgaussian vectors outer products.

**Lemma 8** (Hsu et al. [2011]). Let $z_1, \ldots, z_n \in \mathbb{R}^p$ be i.i.d random subgaussian vectors with parameter $\nu$, then for all $\delta \in (0, 1)$,

$$\mathbb{P}[||n^{-1} \sum_{i \in [n]} z_i z_i' - I||_2 > 2 \epsilon(n, \delta)] \leq \delta$$

where

$$\epsilon(n, \delta) = \nu^2 \left( \sqrt{\frac{8(p \log(9) + \log(2/\delta))}{n}} + \frac{p \log(9) + \log(2/\delta)}{n} \right).$$

The above result can easily be extended to variables with arbitrary covariance matrix.

**Lemma 9.** Let $x_1, \ldots, x_n \in \mathbb{R}^p$ be independent random vectors satisfying $x_i = \Sigma^{1/2} z_i$ with $z_1, \ldots, z_n$ being independent subgaussian vectors with parameter $\nu$ and $\Sigma^{1/2}$ is the symmetric matrix square root of $\Sigma$. If $\Lambda_{\max}(\Sigma) < \infty$ and $\Lambda_{\min}(\Sigma) > 0$, then for all $\delta \in (0, 1)$

$$\mathbb{P}[||n^{-1} \sum_{i \in [n]} x_i x_i' - \Sigma||_2 > 2 \Lambda_{\max}(\Sigma) \epsilon(n, \delta)] \leq \delta$$

and

$$\mathbb{P}[||n^{-1} \sum_{i \in [n]} x_i x_i' - (\Sigma)^{-1}||_2 > 2 \epsilon(n, \delta)/\Lambda_{\min}(\Sigma)] \leq \delta.$$
Proof. We have that
\[ \|n^{-1}X'X - \Sigma\|_2 = \|\Sigma^{1/2}(n^{-1}Z'Z - I_p)\Sigma^{1/2}\|_2 \leq \Lambda_{\text{max}}(\Sigma)\|n^{-1}Z'Z - I_p\|_2 \]
and (22) follows from (21).

Similarly, we can write
\[ \|(n^{-1}X'X)^{-1} - \Sigma^{-1}\|_2 = \|\Sigma^{-1/2}((n^{-1}Z'Z)^{-1} - I_p)\Sigma^{-1/2}\|_2 \leq \Lambda_{\text{min}}(\Sigma)\|(n^{-1}Z'Z)^{-1} - I_p\|_2 \]
and (23) follows from (21). \(\square\)

7.2 Proofs and Technical Results

For convenience, we restate technical conditions used in the paper.

Assumption 1. The matrix \(X = (x_1, \ldots, x_n)' \in \mathbb{R}^{n \times p}\) has independent rows that satisfy \(x_i = \Sigma^{1/2}z_i\), where \(\{z_i\}_i\) are i.i.d. subgaussian random variables with \(Ez_i = 0, Ez_i z_i' = I\) and \(||z_i||_{\psi_2} \leq K\). Furthermore, there exist two constants \(C_{\min}, C_{\max} > 0\) such that

\[ 0 < C_{\min} \leq \Lambda_{\min}(\Sigma) \leq \Lambda_{\max}(\Sigma) \leq C_{\max} < \infty. \]

Assumption 2. The errors \(\epsilon_1, \ldots, \epsilon_n\) are i.i.d. with \(\epsilon_i \in B_{\psi_2}(1)\).

Assumption 3. There are two constants \(\bar{\beta}\) and \(\bar{\theta}\) such that \(||\beta|| \leq \bar{\beta} < \infty\) and \(||\theta|| \leq \bar{\theta} < \infty\).

Assumption 4. \(|S| = C_{S} n^{\alpha_S}\) and \(|T| = C_{T} n^{\alpha_T}\) for some \(\alpha_S \in (0, 1)\) and \(\alpha_T \in (0, 1/3)\) and constants \(C_S, C_T > 0\).

Assumption 5. Define
\[ D_{SS} = n^{-1}X'_S\text{diag}(\exp(-X\theta))X_S. \]

There exist constants \(0 \leq D_{\min}, D_{\max} \leq \infty\) such that
\[ \lim_{n \to \infty} \mathbb{P}[\Lambda_{\text{max}}(D_{SS}) \leq D_{\max}] = 1, \quad \text{and} \quad \lim_{n \to \infty} \mathbb{P}[\Lambda_{\text{min}}(D_{SS}) \geq D_{\min}] = 1. \]

7.3 Proof of Theorem 1

We will split the proof in two parts. In the first part, we show that the vector \(\hat{\beta} = (\hat{\beta}'_S, 0_{SC}')', \) where \(\hat{\beta}_S = (X'_S X_S)^{-1}X'_S y,\) is a strict local minimizer of (2) and \(S = \{j : \beta_j \neq 0\}.\) In the second part, we use results for pseudo-maximum likelihood estimates to establish asymptotic normality of \(\hat{\beta}_S.\)

From Theorem 1 in [Fan and Lv 2009], we need to show that \(\hat{\beta}\) satisfies
\[ X'_S(y - X\hat{\beta}) - n \text{sign}(\hat{\beta}_S) \odot \rho'_\lambda(\hat{\beta}_S) = 0, \quad (24) \]
\[ ||X'_{SC}(y - X\hat{\beta})||_{\infty} < n\rho'_\lambda(0+), \quad (25) \]
and
\[ \Lambda_{\min}(n^{-1}X'_S X_S) > \max_{j \in S} \{ -\rho_j(\|\hat{\beta}_j\|) \}, \] (26)
in order to show that \( \hat{\beta} \) is a strict local minimizer.

Define the events
\[ A_1 = \left\{ \max_{i \in [n]} \exp(|x'_i \theta|) \leq \exp \left( \sqrt{K^2 \Lambda_{\max}(\Sigma_{TT}) \|\theta\|_2^2 \log(2n/\delta)} \right) \right\} \]
where \( T = \{ j : \theta_j \neq 0 \} \) and
\[ A_2 = \{ \Lambda_{\max}((n^{-1}X'_S X_S)^{-1}) \leq 3/\Lambda_{\min}(\Sigma_{SS}) \}. \]

To simplify notation, we define
\[ \bar{\sigma}^2 = \exp \left( \sqrt{K^2 \Lambda_{\max}(\Sigma_{TT}) \|\theta\|_2^2 \log(2n/\delta)} \right). \] (27)

The following two lemma shows that the events \( A_1 \) and \( A_2 \) occur with high probability.

**Lemma 10.** Under the assumptions of Theorem 1, we have that \( P[A_1] \geq 1 - \delta \).

**Proof.** We have
\[ \|x'_i \theta\|_{\Psi_2} \leq \|\Sigma^{1/2} \theta\|_2 \|z_i\|_{\Psi_2} \leq K \|\theta\|_2 \Lambda_{\max}(\Sigma_{TT})^{1/2}. \]
Lemma follows by setting \( t = \sqrt{K^2 \Lambda_{\max}(\Sigma_{TT}) \|\theta\|_2^2 \log(2n/\delta)} \) in (17) and using the union bound. \( \square \)

**Lemma 11.** Suppose that the assumptions of Theorem 1 are satisfied. Furthermore, assume that \( n \) is big enough so that
\[ K^2 \left( \sqrt{8(C_n n^\alpha_S \log(9) + \log(2/\delta)) n} + \frac{C_n n^\alpha_S \log(9) + \log(2/\delta)}{n} \right) < 1. \]
Then \( P[A_2] \geq 1 - \delta \).

**Proof.** We have that
\[ \| (n^{-1}X'_S X_S)^{-1} \|_2 \leq \|\Sigma_{SS}^{-1}\|_2 + \| (n^{-1}X'_S X_S)^{-1} - \Sigma_{SS}^{-1} \|_2 \leq 3/\Lambda_{\min}(\Sigma_{SS}) \]
with probability \( 1 - \delta \) using (23) and the fact that \( n \) is large enough so that \( \epsilon(n, \delta) < 1 \). \( \square \)

Recall that \( \hat{\beta}_S \) is an ordinary least squares estimator using variables in \( S \), so that
\[ \hat{\beta}_S - \beta_S = (X'_S X_S)^{-1}X'_S \eta = (X'_S X_S)^{-1}X'_S \text{diag}(e^{X\theta/2}) \epsilon. \]
Define

\[ M := (X_S^t X_S)^{-1} X_S^t \text{diag}(e^{X\theta}) X_S (X_S^t X_S)^{-1}. \]

Conditioned on \( X \), using Lemma 4 we have that \( e_j'(\hat{\beta}_S - \beta_S) \) is subgaussian with parameter \( \sqrt{2m_{jj}}, j \in S \). Therefore

\[ \mathbb{P}(||\hat{\beta}_S - \beta_S||_\infty > t | X \leq 2s \exp \left( - \frac{t^2}{2 \max_{j \in S} m_{jj}} \right). \] (28)

On the event \( A_1 \cap A_2 \),

\[ \max_{j \in S} m_{jj} \leq n^{-1} \bar{s}^2 \Lambda_{\text{max}}(n^{-1} X_S^t X_S)^{-1} \leq \frac{3 \bar{s}^2}{\Lambda_{\text{min}}(\Sigma_{SS}) n}. \]

Setting \( t = \sqrt{2(\max_{j \in S} m_{jj}) \log(2s/\delta)} \) in (28) and conditioning on the event \( A_1 \cap A_2 \) and its complement, we have

\[ ||\hat{\beta}_S - \beta_S||_\infty \leq \sqrt{\frac{6 \exp(\sqrt{C \log(2n/\delta)}) \log(2s/\delta)}{\Lambda_{\text{min}}(\Sigma_{SS}) n}} \] (29)

where \( C = K^2 \Lambda_{\text{max}}(\Sigma_{TT}) ||\theta||_2^2 \) with probability \( 1 - 3\delta \). Under the assumptions, we have that \( ||\hat{\beta}_S - \beta_S||_\infty \leq \lambda \).

Using the result obtained above, we have that

\[ \min_{j \in S} |\hat{\beta}_j| \geq \min_{j \in S} |\beta_j| - ||\hat{\beta}_S - \beta_S||_\infty \]

\[ \geq \beta_{\text{min}} - ||\hat{\beta}_S - \beta_S||_\infty \]

\[ \geq \beta_{\text{min}}/2 \gg \lambda, \]

since \( \beta_{\text{min}} \geq n^{-\gamma} \log n \) with \( \gamma \in (0, 1/2] \). This gives us that \( \rho'(\hat{\beta}_S) = 0 \) and \( \max_{j \in S} \{-\rho_j''(||\hat{\beta}_j||)\} = 0 \) showing (24) and (26).

Using Lemma 5 and Lemma 7.1, we write \( X_j \in \mathbb{R}^n \) as \( X_j = X_S \tau_j + E_j \), \( j \in S^C \), with \( E_j \) having elements that are subgaussian with parameter \( K \sqrt{\Sigma_{jj}|S} \).

Therefore

\[ n^{-1} X_j'(y - X \hat{\beta}) = n^{-1} (X_S \tau_S + E_j)'(I-P_S)y = n^{-1} E_j'(I-P_S)\text{diag}(\exp(X\theta/2))\varepsilon. \]

Denote

\[ n_j = n^{-2} ||E_j||_2^2 \max_{i \in n} \exp(x_i' \theta) \]

and observe that \( n_j \geq n^{-2}||E_j'(I - P_S)\text{diag}(\exp(X\theta/2))||_2^2 \). Condition on \( X \), then for any \( j \in S^C \),

\[ \mathbb{P}(|n^{-1} E_j'(I - P_S)\text{diag}(\exp(X\theta/2))\varepsilon| > t) \leq 2 \exp(-t^2/n_j). \] (30)

Using the union bound together with Lemma 5

\[ \max_{j \in S^C} ||E_j||_2^2 \leq 3K (\max_{j \in S} \Sigma_{jj}|S) n \]

21
with probability at least 1 − (p − s) \exp(-2n). Conditioning on the event \( A_1 \) and its complement
\[
\max_{j \in \mathcal{S}^c} n_j \leq 3K \left( \max_{j \in \mathcal{S}} \Sigma_{j|\mathcal{S}} \right) n^{-1} \exp \left( \sqrt{C \log(2n/\delta)} \right)
\]
where \( C = K^2 \Lambda_{\max}(\Sigma_{TT}) \| \theta \|_2^2 \) with probability \( 1 - \delta - (p - s) \exp(-2n) \). Picking
\[
t = \sqrt{\left( \max_{j \in \mathcal{S}^c} n_j \right) \log(2(p-s)/\delta)}
\]
in (30) and combining with the above, we have shown that
\[
\| n^{-1} X_{\mathcal{S}^c}' (y - X\hat{\beta}) \|_\infty < \sqrt{\left( \max_{j \in \mathcal{S}^c} n_j \right) \log(2(p-s)/\delta)}
\]
with probability \( 1 - 2\delta - (p-s) \exp(-2n) \). Since
\[
\sqrt{3K \left( \max_{j \in \mathcal{S}} \Sigma_{j|\mathcal{S}} \right) n^{-1} \exp \left( \sqrt{C \log(2n/\delta)} \right) \log(2(p-s)/\delta)} \leq \lambda/2 < \rho'(0+)
\]
we have shown that \( \hat{\beta} \) is a strict local minimizer. This finishes the proof of the first part.

We are now ready to show asymptotic normality of \( \hat{\beta} \). Define \( W = \text{diag}(\exp(-X\theta/2)) \). From the proof of the first part and the assumption (5), we have that
\[
\hat{\beta} - \beta = (X'_S X_S)^{-1} X' W \epsilon = n^{-1/2} (\Sigma_{SS})^{-1} (\mathbb{E} D_{SS})^{1/2} \epsilon + o_p(1),
\]
where the small order term is understood under the \( L_2 \) norm. Write
\[
a'(\hat{\beta} - \beta) = \sum_{i \in [n]} c_i \epsilon_i
\]
where \( c_i = n^{-1/2} a'(\Sigma_{SS})^{-1}(\mathbb{E} D_{SS})^{1/2} \). It follows that
\[
\sum_{i \in [n]} \text{Var}(c_i \epsilon_i) = n^{-1} a'(\Sigma_{SS})^{-1}\mathbb{E} D_{SS}(\Sigma_{SS})^{-1} a,
\]
and
\[
\sum_{i \in [n]} \mathbb{E}|c_i \epsilon_i|^3 = n^{-3/2} \sum_{i \in [n]} |a'(\Sigma_{SS})^{-1}(\mathbb{E} D_{SS})^{1/2} \epsilon_i|^3 \\
\leq C n^{-3/2} \| a'(\Sigma_{SS})^{-1} \|^3 \sum_{i \in [n]} \| (\mathbb{E} D_{SS})^{1/2} \|^3 \\
= o(1).
\]
This allows us to apply the Lyapunov’s theorem to conclude the proof of the theorem.
7.4 Proof of Theorem 2
Consider an oracle that performs the second stage of HIPPO with full knowledge of the sparsity set \( T \), resulting in the estimator \( \hat{\theta}_T \), with \( \lambda_T = 0 \). (viz. \( \hat{\theta}_T \) is the pseudo-likelihood maximizer by forming the likelihood with the estimated residuals from the OLS.) Then \( \hat{\theta} = (\hat{\theta}_T, 0) \)' is a strict local minimizer of the program (3) for \( \lambda_T \approx n^{-1/2+\alpha_T} \log(p) \). We derive necessary and sufficient conditions for \( \hat{\beta} \) to be a strict local minimizer of the program (2) akin to those in Theorem 1 in Fan and Lv [2009]. We show that the PML is asymptotically equivalent to the maximum likelihood estimator through a lemma from Hjort and Pollard [1993] and by following arguments similar to Jobson and Fuller [1980]. As opposed to the classical asymptotic theory, we implicitly construct finite sample results because \( |\hat{T}| \) is allowed to grow with \( n \).

Lemma 12. Let \( M = X(X'X)^{-1}X' \) then,

\[
\text{max}_{i \in [n]} \| M_i \| = O_P \left( \frac{1}{n(3-\alpha s)^4} \log(n) \right)
\]

Proof. It is known by Hsu et al. [2011] that with probability at least \( 1 - \delta \),

\[
\| \frac{1}{n} \sum_{i} x_{i,s} x_{i,s} - \Sigma_{S,S} \| = O_P \left( \| \Sigma_{S,S} \| \sqrt{\frac{s + \log(1/\delta)}{n}} \right)
\]

Then we have that

\[
n\| M_i \| = \| x_{i,s} (\frac{X_S^T X_S}{n})^{-1} X_S^T \| \leq \| x_{i,s} \Sigma_{S,S}^{-1} X_S^T \| + \| x_{i,s} \left( (\frac{X_S^T X_S}{n})^{-1} - \Sigma_{S,S}^{-1} \right) X_S^T \|
\]

Controlling first the rightmost term,

\[
\| x_{i,s} \left( (\frac{X_S^T X_S}{n})^{-1} - \Sigma_{S,S}^{-1} \right) X_S^T \| \leq \frac{\| x_{i,s} \Sigma_{S,S}^{-1} X_S^T \| \| x_{i,s} \| \| X_S \| \| X_S^T \|}{\Lambda_{\min}(\frac{X_S^T X_S}{n}) \Lambda_{\min}(\Sigma_{S,S})}
\]

by a result we obtain below, \( \Lambda_{\min}(\frac{X_S^T X_S}{n}) \) and \( \Lambda_{\min}(\Sigma_{S,S}) \) are bounded below by a constant with high probability. By the result above,

\[
\| \frac{X_S^T X_S}{n} - \Sigma_{S,S} \| = O_P(\sqrt{s \log(1/\delta)})
\]

furthermore we have that \( \| X_S \| = O_P(\sqrt{s \log(1/\delta)}) \). Hence the second term is \( O_P((s \log(1/\delta)^{3/2}/\sqrt{n}) \).

Now consider the first term, \( \| x_{i,s} \Sigma_{S,S}^{-1} X_S^T \| \). And write \( U_j = \Sigma_{S,S}^{-1/2} X_{j,s} \) then we have that

\[
\| x_{i,s} \Sigma_{S,S}^{-1} X_S^T \|^2 \leq \| U_j \|^2 + \left( \sum_{j \neq i} U_i^T U_j \right) \leq \| U_i \|^2 + \| U_i \| \sqrt{2n \log(2/\delta)}
\]

\[23\]
because
\[ \sum_{j \neq i} U_i^\top U_j \leq \|U_i\| \sqrt{2n \log(2/\delta)} \]
with probability $1 - \delta$ by the sub-Gaussianity of $\{U_j\}$. Thus, $\|x_{i,S} \Sigma_{S,S}^{-1} X_S^\top \| = O(s \log(1/\delta) + \sqrt{s n \log(2/\delta)})$. So, assuming that $s << n$ then
\[ \|M_i\| = O_P\left( s^{1/4} \sqrt{\log(1/\delta)} \right) \]

**Lemma 13.** Consider both the empirical residuals, $\hat{\eta}$, and the true residuals, $\eta$. Then
\[ \max_{i \in [n]} |\hat{\eta}_i^2 - \eta_i^2| = o_P\left( \frac{1}{n^{1/2+\gamma}} \right) \]
for any $\gamma \in [0, (1 - \alpha S)/2)$.

**Proof.** First let us expand the terms in question:
\[ \hat{\eta}_i^2 - \eta_i^2 = [(I - M)\eta]_i^2 - \eta_i^2 = [\eta - M\eta]_i^2 - \eta_i^2 = (M\eta)_i^2 - 2\eta_i (M\eta)_i^2 \]
Now we take a closer look at the right hand side,
\[ (M\eta)_i^2 - 2\eta_i (M\eta)_i^2 = \sum_{i}^{|n|} M_{i,j} \eta_j - 2\eta_i \sum_{j}^{|n|} M_{i,j} \eta_j \]
Notice that the true residuals $\eta$ are IID sub-Gaussian with parameter at most $\bar{\sigma}$. Hence, with probability $1 - \delta$
\[ \left| \sum_{i}^{|n|} M_{i,j} \eta_j \right| \leq \|M_i\| \bar{\sigma} \sqrt{2 \log(2/\delta)} \]
Hence, we find that
\[ |(M\eta)_i^2 - 2\eta_i (M\eta)_i^2| = O(\|M_i\|\bar{\sigma}^2 \log(1/\delta)) \]
Below we show that there is a constant $C > 0$ such that
\[ \bar{\sigma}^2 = O(\exp(\sqrt{C\|\theta\|^2 \log(2n/\delta)}) ) \]
with probability at least $1 - \delta$. Hence,
\[ \max_{i \in [n]} |\hat{\eta}_i^2 - \eta_i^2| = O\left( \frac{s^{1/4} (\log(n/\delta))^2}{n^{3/4}} \exp(\sqrt{C\|\theta\|^2 \log(2n/\delta)}) \right) \]
with probability $1 - \delta$. Because $s = n^\alpha$ we have our result then this reduces to,

$$\max_{i \in [n]} |\hat{\eta}_i^2 - \eta_i^2| = \mathcal{O}(\log(n/\delta)^2 \exp(\sqrt{C}\|\theta\|^2\log(2n/\delta)))$$

Because both $\log(n/\delta)^2$ and $\exp(\sqrt{C}\|\theta\|^2\log(2n/\delta))$ are subpolynomial in $n$, so,

$$\max_{i \in [n]} |\hat{\eta}_i^2 - \eta_i^2| = \mathcal{O}_P\left(\frac{1}{n^{1/2+\gamma}}\right)$$

where $\gamma > 0$ may be arbitrarily close to but less than $(1 - \alpha S)/2$.

**Lemma 14.** Consider the difference of the pseudo-likelihood gradient and the true likelihood gradient,

$$\hat{U}_n - U_n = \sum_{i} \frac{\hat{\eta}_i^2 - \eta_i^2}{\sqrt{n}} e^{-x_i^\top \theta} x_i$$

If $\alpha_T < (1 - \alpha_S)/2$ then

$$\|\hat{U}_n - U_n\| = o_P(1)$$

**Proof.** By the above lemma,

$$\max_{i \in [n]} \left|\sqrt{n}(\hat{\eta}_i^2 - \eta_i^2)\right| = o_P\left(\frac{1}{n^{\gamma}}\right)$$

Moreover, we know that $\max_{i \in [n]} e^{-x_i^\top \theta} X_i = O(\sqrt{n} \phi(n))$ where $\phi(n)$ is sub-polynomial in $n$. Because $\sqrt{t} = n^{\alpha_T/2}$ and $\alpha_T < 2\gamma$ then

$$\max_{i \in [n]} \left|\sqrt{n}(\hat{\eta}_i^2 - \eta_i^2)e^{-x_i^\top \theta} X_i\right| = o_P(1)$$

Thus the average of the summands is $o_P(1)$ and we have our result.

**Lemma 15.** Consider the difference of the pseudo-likelihood Hessian and the true Hessian,

$$\hat{V}_n - V_n = \frac{1}{n} \sum_{i} (\hat{\eta}_i^2 - \eta_i^2)e^{-x_i^\top \theta^T x_i}$$

If $\alpha_T < (3 - \alpha_S)/4$ then

$$\|\hat{V}_n - V_n\| = o_P(1)$$

**Proof.** This proof follows in the same way as Lemma 14 mutatis mutandis.

**Lemma 16.** Let $\hat{\theta}_T$ be the pseudo likelihood maximizer and $|T| = n^{\alpha_T}$ with $\alpha_T \in (0, 1)$. And define the gradient and hessian,

$$\hat{U}_n = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} x_{i,T} - \hat{\eta}_i^2 e^{-x_{i,T}^\top \theta_T} x_{i,T}$$

$$\hat{V}_n = \frac{1}{n} \sum_{i} (\hat{\eta}_i^2 - \eta_i^2)e^{-x_i^\top \theta^T x_i}$$
\[
\hat{V}_n = \frac{1}{n} \sum_{i=1}^{n} \eta_i^2 e^{-x_i' \tau \theta} x_i' T
\]
then we have that,
\[
||\sqrt{n}(\hat{\theta}_T - \theta_T) - \hat{V}_n^{-1} \hat{U}_n|| = o_P(1)
\]
Proof. Denote the function \( \hat{L}_n(\hat{\theta}_T) = \sum_{i=1}^{n} \ell(\theta_T + \frac{\hat{\eta}_i}{\sqrt{n}} | x_i, \hat{\eta}) \) which has minimizer \( \sqrt{n}(\hat{\theta}_T - \theta_T) \). Consider the Taylor expansion for \( \hat{L}_n \) about 0,
\[
\hat{L}_n(\hat{\theta}_T) = \hat{L}_n(0) + \hat{U}_n^\top \theta_T + \hat{\theta}_T^\top \hat{V}_n \theta_T + \hat{R}_n(r \theta_T)
\]
for some \( r \in [0, 1] \). In Llemma[12][13] we devoted ourselves to understanding the first and second order terms in this expansion. We now must concern ourselves with the remainder, third order term.
\[
\hat{R}_n(\theta_T) = \frac{-1}{n \sqrt{n}} \sum_{i=1}^{n} \eta_i^2 e^{-x_i' \theta} (x_i' \hat{\theta}_T)^3
\]
Define \( \theta_T = \hat{V}_n^{-1} \hat{U}_n \) and \( \Delta_n(\delta) = \sup_j |\theta_T - \theta_T^\gamma| \leq \delta \hat{R}_n(r \theta_T) \). We control \( \hat{R}_n \) by decomposing it as \( \hat{R}_n = (\hat{R}_n - R_n) + R_n \).
\[
||\hat{R}_n(\theta_T) - R_n(\theta_T)|| \leq \frac{1}{n \sqrt{n}} \sum_{i=1}^{n} \eta_i^2 |e^{-x_i' \theta T}||x_i T|||\theta||^3 \leq O_P \left( \frac{|\theta||^3}{n^{1+\gamma/2}} \right)
\]
We show in Lemma[10] that \( \bar{\sigma} \) is sub-polynomial in \( n \). Moreover, by the sub-Gaussianity of \( x_i, T, \max_{x_i, T} ||x_i T||^3 = O_P(\sqrt{T}/n^{9/2}) \) modulo logarithmic terms. If we assume that \( \delta < 1 \) then \( ||\theta T||^3 < 8||V_n^{-1} \hat{U}_n||^3 \). We have shown in the previous lemmata that \( ||V_n^{-1} \hat{U}_n - V_n^{-1} U_n|| = o_P(1) \) under our assumptions. By standard maximum likelihood estimation analysis \( ||V_n^{-1} U_n|| = O_P(\sqrt{T}) = O_P(n^{\alpha_T/2}) \). Hence, the RHS of eq. [32] is of the order \( O_P(n^{3\alpha_T - 1 - \gamma}) \) modulo sub-polynomial terms. Due to the assumption that \( \alpha_T < 1/3 \) we have that \( ||\hat{R}_n - R_n|| = o_P(1) \). Notice that this convergence is uniform over \( \theta_T \) because of the specific form of eq. [32]

What remains to be shown is that \( R_n(\theta_T) = o_P(1) \) uniformly over \( \bar{\theta}_T - \theta_T^\gamma \) for some small \( \delta \). By identical arguments to those above we see that \( ||e^{-x_i' \tau \theta T}|| = O_P(||x_i T||n^{3\alpha_T/2}) \) uniformly over \( i \) modulo logarithmic terms. So the function \( f_i(\eta_i, x_i, T, \theta) = \eta_i^2 e^{-x_i' \tau \theta T} \) may be bounded uniformly over a domain of radius \( O_P(n^{3\alpha_T/2}) \). \( f_i(\eta_i, x_i, T, \theta) \leq ||\eta_i^2 x_i T n^{3\alpha_T/2}|| \)
and \( \mathbb{E} \eta_T^2 |x_{ij}|^3 n^{3\alpha_T/2} = O_p(\sigma^2 n^{3\alpha_T}) \). Finally, we may invoke the uniform law of large numbers yielding \( \frac{1}{\sqrt{n}} R_n(\theta_T) \overset{P}{\rightarrow} 0 \) if \( \alpha_T < 1/3 \) as \( \hat{\sigma} \) is sub-polynomial in \( n \).

We have shown that \( \Delta(\delta) \overset{P}{\rightarrow} 0 \) if \( \delta \) is decreasing. By Lemma 2 in [Hjort and Pollard 1993], we know that if \( \Lambda_{\text{min}}(\hat{V}_n) \) is bounded below in probability and \( \Delta(\delta) \overset{P}{\rightarrow} 0 \) uniformly then the minimizer of \( L_n \) converges in probability to the minimizer of its quadratic approximation, viz. \( ||\sqrt{n}(\hat{\theta}_T - \theta_T) - \hat{V}_n^{-1} \hat{U}_n|| = O_p(1) \). We have established the latter condition while the former is a direct result of Lemma 15.

Now, we can form the decomposition,

\[
||\sqrt{n}(\hat{\theta}_T - \theta_T) - \hat{V}_n^{-1} \hat{U}_n|| \leq ||\sqrt{n}(\hat{\theta}_T - \theta_T) - \hat{V}_n^{-1} \hat{U}_n|| + ||\hat{V}_n^{-1} \hat{U}_n - \hat{V}_n^{-1} \hat{U}_n||
\]

\[
\leq ||\hat{V}_n^{-1} \hat{U}_n - \hat{V}_n^{-1} \hat{U}_n|| + ||\hat{V}_n^{-1} \hat{U}_n - \hat{V}_n^{-1} \hat{U}_n|| + o_P(1)
\]

\[
\leq ||\hat{V}_n^{-1}|| \|\hat{U}_n - \hat{U}_n\| + ||\hat{V}_n^{-1} - \hat{V}_n^{-1}\| ||\hat{U}_n\| + o_P(1)
\]

(33)

All of these terms are decaying in probability because, \( ||\hat{V}_n^{-1} - \hat{V}_n^{-1}\| ||\hat{V}_n^{-1}|| ||\hat{V}_n^{-1}|| \). Combining these results we find that

\[
||\sqrt{n}(\hat{\theta}_T - \theta_T) - \hat{V}_n^{-1} \hat{U}_n|| = o_P(1)
\]

(34)

We are now in a position to establish the oracle property of \( ||n^{1-\alpha_T}(\hat{\theta}_T - \theta_T)|| = O_P(1) \)

Specifically, by standard MLE analysis we know that for a fixed coordinate in \( j \in T \), \( (\hat{V}_n^{-1} \hat{U}_n)_j = O_P(1) \). Thus, \( ||\sqrt{n}(\hat{\theta}_T - \theta_T)|| \leq ||\sqrt{n}(\hat{\theta}_T - \theta_T) - \hat{V}_n^{-1} \hat{U}_n|| + ||\hat{V}_n^{-1} \hat{U}_n|| = O_P(n^{\alpha_T/2}) \). Finally, we establish that the estimator \( \hat{\theta}_T = (\hat{\theta}_T^T, \hat{\theta}_{SC}^T)^T \) is a strict local minimizer of the program (3).

The first order conditions for a local optima of the SCAD penalized likelihood of \( \sigma \) are,

\[
\sum_j^{[n]} (1 - \eta_j^2 e^{-x_j^T \hat{\theta}}) x_{j,i} - n \rho'_{\lambda_n}(\hat{\theta}_i) = 0, \text{ if } \theta_i \neq 0
\]

(35)

\[
\sum_j^{[n]} (1 - \eta_j^2 e^{-x_j^T \hat{\theta}}) x_{j,i} < n \rho'_{\lambda_n}(0+), \text{ if } \theta_i = 0
\]

(36)

where \( \rho'_{\lambda_n}(a) = \text{sign}(a) \rho'_{\lambda_n}(a) \). The second order condition is given by,

\[
\Lambda_{\text{min}} \left( \frac{1}{n} X_1 \text{diag}\{\exp(-x_i \hat{\theta}_i)\} X_1^T \right) > \kappa_{\lambda_n}(\theta_1)
\]

(37)

where \( \kappa_{\lambda_n}(\theta) = \max_{j \in T \{-\hat{\rho}''_{\lambda_n}(|\theta_j|)\}} \).

By the previous findings we have that uniformly over \( j \), \( |\hat{\theta}_j| > |\theta_j| - O_P(n^{1/2}) \) so if \( \lambda_T = \omega(n^{1/2}) \) and \( \theta_j > C \lambda_T \) for a \( C > 0 \) specific to \( \rho \),

27
eq. (35) follows. Moreover, by assumption 5, and similar arguments eq. (37) holds. What remains to be shown is eq. (36). Recall the decomposition of $x_i$ in Lemma 7

$$
\left\| \sum_{i=1}^{n} (1 - \hat{\eta}_i^2 e^{-x_i(\hat{\theta})}) x_{i,T} \right\|_\infty = \left\| \sum_{i=1}^{n} (1 - \hat{\eta}_i^2 e^{-x_i(\hat{\theta})}) (x_{i,T^\circ \tau_i} + E_i) \right\|_\infty 
$$

$$
= \left\| \sum_{i=1}^{n} (1 - \hat{\eta}_i^2 e^{-x_i(\hat{\theta})}) E_i \right\|_\infty \leq \left\| \sum_{i=1}^{n} (\hat{\eta}_i^2 - \eta_i^2) e^{-x_i(\hat{\theta})} E_i \right\|_\infty + \left\| \sum_{i=1}^{n} (1 - \eta_i^2 e^{-x_i(\hat{\theta})}) E_i \right\|_\infty
$$

(38)

We will soon show that $e^{-x_i(\theta - \hat{\theta})} = o_\nu(1)$ and know by Lemma 10 that $e^{-x_i^2(\theta) - \hat{\theta}}$ is $O_\nu(\phi(n))$ where $\phi(n)$ is subpolynomial in $n$. Hence,

$$
\left\| \sum_{i=1}^{n} (\hat{\eta}_i^2 - \eta_i^2) e^{-x_i(\hat{\theta})} E_i \right\|_\infty \leq \sqrt{\sum_{i=1}^{n} (\hat{\eta}_i^2 - \eta_i^2)^2 \sum_{i=1}^{n} \|E_i\|_\infty^2},
$$

$$
\left\| \sum_{i=1}^{n} (1 - \eta_i^2 e^{-x_i(\hat{\theta})}) E_i \right\|_\infty \leq \sqrt{\sum_{i=1}^{n} (1 - \eta_i^2)^2 \sum_{i=1}^{n} \|E_i\|_\infty^2} \leq O_\nu(\phi(n)) O_\nu(n \log |T^C|) = O_\nu(n^{1/2 - \gamma} \sqrt{\phi(n) \log(p)})
$$

(39)

This follows from the fact that $E_{ij}^2$ is sub-exponential, hence, $\max_j E_{ij}^2 = O(\log |T^C|)$. We now show that $e^{-x_i(\theta - \hat{\theta})} = o_\nu(1)$ from the subgaussianity of $||x_i,T||$. Specifically, because we know that $\theta - \hat{\theta} = O_\nu(n^{\alpha_T-1/2})$ we will prove this uniformly over a neighborhood of radius $O(n^{(\alpha_T-1/2)})$. Notice that over this neighborhood, $e^{-x_i(\theta - \hat{\theta})} \leq \exp(r ||x_i,T||/n^{(1-\alpha_T)/2})$ for some $r > 0$.

$$
P\{r ||x_i,T|| > vn^{\alpha_T/2}\} \leq Ce^{-cr} \Rightarrow P\{r ||x_i,T|| > vn^{\alpha_T/2}\} \leq C e^{-cr}
$$

$$
\Rightarrow P\{r ||x_i,T|| > vn^{\alpha_T/2}\} \leq C \frac{1}{\nu(n^{1-\alpha_T})}
$$

(40)

In a similar way we may bound the square of $\exp(r ||x_i,T||/n^{(1-\alpha_T)/2})$ in probability. Now in a uniform bounding technique similar to eq. (32) we can show that the second term in the RHS of eq. (39) is $O_\nu(n^{\alpha_T-1/2} \log(n))$. Define the variables $\xi_i = e^{-x_i(\theta - \hat{\theta})} - 1$ and $b_n = o(n^{1/2-\alpha_T})$. We see that under the same neighborhood for $\theta - \hat{\theta}$,

$$
P\{\xi_i > \frac{1}{cb_n}\} \leq C[(1 + \frac{1}{cb_n})^{-c}] = o(1)
$$

Hence, $\xi_i = o_\nu(n^{\alpha_T-1/2} \log(n))$ and we may bound the remaining term.

$$
\left| \sum_{i=1}^{n} (1 - \hat{\eta}_i^2 e^{-x_i(\hat{\theta})}) E_{i,j} \right| = \left| \sum_{i=1}^{n} (1 - \eta_i^2 e^{-x_i(\theta - \hat{\theta})}) E_{i,j} \right|
$$

$$
\leq \left| \sum_{i=1}^{n} (1 - \hat{\eta}_i^2) E_{i,j} \right| + \left| \sum_{i=1}^{n} \xi_i E_{i,j} \right| \leq O_\nu(n \sqrt{\alpha_T}) + O_\nu(n^{\alpha_T+1/2} \log(p))
$$

(41)
by the central limit theorem and Cauchy-Schwartz. Similarly, we can bound this uniformly over $j$ and obtain an additional $\log(p)$ factor. Hence, $\lambda_T \asymp n^{-1/2+\alpha_T} \log(p) \log(n)$ for eq. \ref{eq:bound_theta} to hold. Thus $\hat{\theta}$ is the strict local minimizer of the SCAD penalized program.

The weak central limit theorem in \ref{eq:WCLT_theta} is a direct application of the standard CLT to \ref{eq:WCLT_theta}. Specifically, $a' \mathbf{V}_n \mathbf{U}_n \xrightarrow{p} \mathcal{N}(0, \zeta)$ because the Fisher information of the true likelihood with respect to $\theta$ is $\Sigma_T$. While $a' (\sqrt{n}(\hat{\theta} - \theta) - \mathbf{V}_n \mathbf{U}_n) \xrightarrow{p} 0$ by \ref{eq:WCLT_theta} and the construction of $\hat{\theta}$.

### 7.5 Proof of Theorem \[3\]

The proof follows the same lines as the proof of Theorem \ref{thm:1}, however, there are some technical challenges that arise from having only an estimate of the variance.

We define $\hat{\mathbf{W}} = \text{diag}(\exp(-X\hat{\theta}/2))$ and $\mathbf{W} = \text{diag}(\exp(-X\theta/2))$. Furthermore, we will use $\mathbf{D}_{SS} = n^{-1}X'_{S} \mathbf{W}^2 X_{S}$ and $\mathbf{D}_{SS} = n^{-1}X'_{S} \mathbf{W}^2 X_{S}$.

We proceed to show that $\hat{\beta}_w = (\hat{\beta}_w', 0_{S^c}')'$ is a strict local minimizer of \ref{eq:SCAD_penalized_program} where $\hat{\beta}_{w,S} = n^{-1}\mathbf{D}_{SS}^{-1}X'_{S} \mathbf{W}^2 y$, by showing that $\hat{\beta}_w$ satisfies

$$X'_{S} \hat{\mathbf{W}} (\hat{\mathbf{W}} y - \mathbf{W} \hat{\beta}) - n \text{sign}(\hat{\beta}_{w,S}) \odot \rho'(\hat{\beta}_{w,S}) = 0,$$

$$||X'_{S} \hat{\mathbf{W}} (\hat{\mathbf{W}} y - \mathbf{W} \hat{\beta}_w)||_\infty < n \rho'(0+),$$

and

$$\Lambda_{\min}(n^{-1}X'_{S} \hat{\mathbf{W}}^2 X_{S}) > \max_{j \in S} \{-\rho''(||\hat{\beta}_w,j||)\}.$$  \tag{44}

Recall the definition of the event $A_1$ from the proof of Theorem \ref{thm:1}

$$A_1 = \left\{ \max_{i \in [n]} \exp(||x'_i(\theta)||) \leq \exp\left( \sqrt{K^2 \Lambda_{\max}(\Sigma_{TT}) ||\theta||^2_2 \log(2n/\delta)} \right) \right\},$$

with $\mathbb{P}[A_1] \geq 1 - \delta$. Also, recall that

$$\sigma^2 = \exp\left( \sqrt{K^2 \Lambda_{\max}(\Sigma_{TT}) ||\theta||^2_2 \log(2n/\delta)} \right).$$

Next, we define the event

$$A_3 = \{ \max_{i \in [n]} |x'_i(\hat{\theta} - \theta)| \leq K||\hat{\theta} - \theta||_2 \Lambda_{\max}(\Sigma_{TT}) \sqrt{\log(2n/\delta)} \}$$

and note that $||x'_i(\hat{\theta} - \theta)||_2 \leq K||\hat{\theta} - \theta||_2 \Lambda_{\max}^{1/2}(\Sigma_{TT})$, since under the assumptions $\hat{\theta}$ has the same support as $\theta$. Using \ref{eq:bound_theta} and the union bound, we have that $\mathbb{P}[A_3] \geq 1 - \delta$.

We will also use the event

$$A_4 = \{ \max_{i \in [n]} (\hat{\theta} - \theta)'x_{i,T}x'_{i,T}(\hat{\theta} - \theta) \leq K^2 \Lambda_{\max}(\Sigma_{TT}) ||\hat{\theta} - \theta||^2_2 \log(2n/\delta) \}.$$
Setting \( u = K^{1/2} \Lambda_{\text{max}}(\Sigma_{TT}) \| \hat{\theta} - \theta \|_2 \sqrt{\log(2n/\delta)} \) in (18) and applying the union bound, we obtain that \( \mathbb{P}[A_4] \geq 1 - \delta. \)

Finally, define the event

\[
A_5 = \{ \Lambda_{\text{max}}(n^{-1}X'_T X_T) \leq 3\Lambda_{\text{max}}(\Sigma_{TT}) \}.
\]

Similar to the proof of Lemma 11 we have that \( \mathbb{P}[A_5] \geq 1 - \delta \) for \( n \) large enough so that \( \epsilon(n, \delta) < 1 \), with \( \epsilon(n, \delta) \) defined in Lemma 8.

In the following analysis, we condition on the event \( A_1 \cap A_3 \cap A_4. \)

The following decomposition

\[
\beta_{w,S} - \beta_{w,S} = n^{-1}(D_{SS} - D_{SS}^{1}X'_S(W^2 - W^2))\eta \\
+ n^{-1}(D_{SS} - D_{SS}^{1}X'_S W^2)\eta \\
+ n^{-1}D_{SS}X'_S(W^2 - W^2)\eta \\
+ n^{-1}D_{SS}X'_S W^2\eta
\] (45)

will be useful for establishing a bound on \( \| \beta_{w,S} - \beta_{w,S} \|_\infty \). We investigate each of the terms separately.

Let \( \sigma^2(x, \theta) = \exp(x'\theta) \). First, we will need to control the deviation of \( \sigma^{-2}(x, \hat{\theta}) \) from \( \sigma^{-2}(x, \theta) \). Using the Taylor expansion

\[
\frac{1}{\sigma^2(x_i, \hat{\theta})} = \frac{1}{\sigma^2(x_i, \theta)} - \frac{2}{\sigma^3(x_i, \theta)} \frac{\partial \sigma(x_i, \theta)}{\partial \theta}(\hat{\theta} - \theta) \\
+ (\hat{\theta} - \theta)^3 \frac{3[(\partial \sigma / \partial \theta)(x, \xi)]'(\partial \sigma / \partial \theta)(x, \xi) - \sigma(x, \xi)(\partial^2 \sigma / \partial \theta^2)(x, \xi)}{\sigma^4(x, \xi)}(\hat{\theta} - \theta)
\]

where \( \xi \) satisfies \( ||\xi - \theta||_2 \leq ||\xi - \theta||_2. \)

On the event \( A_1 \cap A_3 \), we have

\[
\max_{i \in [n]} \left| \frac{2}{\sigma^3(x_i, \theta)} \frac{\partial \sigma(x_i, \theta)}{\partial \theta}(\hat{\theta} - \theta) \right| \\
= \max_{i \in [n]} |\exp(x_i'\theta)x_i'(\hat{\theta} - \theta)| \\
\leq \hat{\sigma}^2 \max_{i \in [n]} |x_i'(\hat{\theta} - \theta)| \\
\leq C||\theta - \theta||_2 \exp \left( C||\theta||_2 \sqrt{\log(2n/\delta)} \right) \log(2n/\delta)
\] (46)

where \( C = K^{1/2} \Lambda_{\text{max}}(\Sigma_{TT}). \)

Basic calculus gives us that \( T_i = |\tau_{ab}|_{ab} \) with

\[
\tau_{ab} = \frac{\exp(-x'_i \theta)}{2} x_{ia} x_{ib}.
\]

30
On the event $A_1 \cap A_4$

$$\max_{i \in [n]} (\hat{\theta} - \theta)' T_i (\hat{\theta} - \theta) \leq (\sigma^2/2) K^2 \Lambda_{\max}(\Sigma_{TT}) \|\hat{\theta} - \theta\|^2_2 \log(2n/\delta). \quad (47)$$

Combining (46) and (47), we have

$$\| \hat{\bf W}^2 - W^2 \|_2 \leq \sigma^2 C \|\hat{\theta} - \theta\|_2 (1 + C \|\hat{\theta} - \theta\|_2/2) \log(2n/\delta) \quad (48)$$

where $C = K \Lambda_{\max}^{1/2}(\Sigma_{TT})$. With this, we have that

$$\Lambda_{\min}(\hat{\bf D}_{SS}) \geq \Lambda_{\min}(\bf D_{SS}) - \|\hat{\bf D}_{SS} - \bf D_{SS}\|_2 \geq D_{\min}/2$$

for sufficiently large $n$. Combining the last two displays

$$\| \hat{\bf D}_{SS}^{-1} - \bf D_{SS}^{-1} \|_2 = \| \hat{\bf D}_{SS}^{-1} (\bf D_{SS} - \hat{\bf D}_{SS}) \bf D_{SS}^{-1} \|_2$$

$$\leq \| \hat{\bf D}_{SS}^{-1} \|_2 \|\bf D_{SS} - \hat{\bf D}_{SS}\|_2 \|\bf D_{SS}^{-1}\|_2$$

$$\leq \frac{2}{D_{\min}^2} \|\bf D_{SS} - \hat{\bf D}_{SS}\|_2. \quad (50)$$

We are now ready to bound each term in (45). For the first term, we have

$$\frac{n^{-1} \| (\hat{\bf D}_{SS}^{-1} - \bf D_{SS}^{-1}) \bf X_S' (\hat{\bf W}^2 - W^2) \eta \|_{\infty}}{D_{\min}^2 \sqrt{n}}$$

$$\leq \frac{n^{-1} \| (\hat{\bf D}_{SS}^{-1} - \bf D_{SS}^{-1}) \bf X_S' (\hat{\bf W}^2 - W^2) \eta \|_2}{D_{\min}^2 \sqrt{n}}$$

$$\leq \frac{n^{-1/2} \| \hat{\bf D}_{SS}^{-1} - \bf D_{SS}^{-1} \|_2 \| n^{-1} \bf X_S' \bf X_S \|^{1/2}_2 \| \hat{\bf W}^2 - W^2 \|_2 \| \eta \|_2}{D_{\min}^2 \sqrt{n}}$$

$$\leq \frac{2 \sigma^2 \eta^2 (3 \Lambda_{\max}(\Sigma_{SS}))^{3/2}}{D_{\min}^2 \sqrt{n}} \|\hat{\theta} - \theta\|_2^2 (1 + C \|\hat{\theta} - \theta\|_2/2) \log^2 (2n/\delta) \|\epsilon\|_2$$

$$\leq \frac{2 \sqrt{3} \sigma^2 \eta^2 (3 \Lambda_{\max}(\Sigma_{SS}))^{3/2}}{D_{\min}^2} \|\hat{\theta} - \theta\|_2^2 (1 + C \|\hat{\theta} - \theta\|_2/2) \log^2 (2n/\delta) \|\epsilon\|_2$$

with probability at least $1 - \exp(-2n)$. The last inequality follows from Lemma 7 with $u = \sqrt{3}$. \vspace{1cm}

31
Similarly, the second term in (55) yields
\[
n^{-1}||D^{-1}_{SS}X'\mathbf{W}^2\eta||_\infty
\leq n^{-1}||D^{-1}_{SS}X'\mathbf{W}^2\eta||_2
\leq \sqrt{\frac{2}{D_{min}^2n}}\|n^{-1}X'SX\|_2\|W^2 - W'^2\|_2\|X'S\mathbf{W}\|_2
\leq \frac{2}{D_{min}^2n}\|n^{-1}X'SX\|_2\|W^2 - W'^2\|_2\|n^{-1}X'S\mathbf{W}^2X\|_2^{1/2}\|\eta\|_2
\leq \frac{6\sqrt{3C\sigma^2}\Lambda_{max}(\Sigma_{SS})D_{max}^{1/2}D_{min}^{1/2}}{D_{min}^2}||\hat{\theta} - \theta||_2(1 + C||\hat{\theta} - \theta||_2/2)\log(2n/\delta)
\] with probability at least \(1 - \exp(-2n)\).

For the third term, we have
\[
n^{-1}||D^{-1}_{SS}X'(\mathbf{W}^2 - W'^2)\eta||_\infty
\leq n^{-1}||D^{-1}_{SS}X'(\mathbf{W}^2 - W'^2)\eta||_2
\leq \frac{1}{D_{min}n}\|n^{-1}X'SX\|_2^{1/2}\|W^2 - W'^2\|_2\|\eta\|_2
\leq \frac{3C\sigma^2\Lambda_{max}(\Sigma_{SS})}{D_{min}}||\hat{\theta} - \theta||_2(1 + C||\hat{\theta} - \theta||_2/2)\log(2n/\delta)
\] with probability at least \(1 - \exp(-2n)\).

Finally, we deal with the forth term in (55). Proceeding as in the proof of (29) we have that
\[
n^{-1}||D^{-1}_{SS}X'S\mathbf{W}^2\eta||_\infty \leq \sqrt{\frac{2\log(2s/\delta)}{D_{min}n}}
\] with probability \(1 - \delta\).

Combining (51), (52), (53) and (54) we have that
\[
||\hat{\mathbf{w}}_{w,S} - \mathbf{w}_{\mathbf{w},S}||_\infty = O(||\hat{\theta} - \theta||_2\exp(C\sqrt{\log n}\log(n))) \ll \lambda
\] with probability at least \(1 - \exp(-2n) - 5\delta\). This also shows that \(\min_{j\in S}||\hat{\mathbf{w}}_j||_{\infty} > \lambda\). Therefore, we have shown (14) and (44).

Using Lemma 5 and Lemma 7.1 we write \(X_j \in \mathbb{R}^n\) as \(X_j = X_S\tau_S + \mathbf{E}_j\), \(j \in S^C\), with \(\mathbf{E}_j\) having elements that are subgaussian with parameter \(K\sqrt{\Sigma_{j|S}}\).
Denote \(\mathbf{P}_{w,S} = \mathbf{I} - \mathbf{W}X_S(X_S\mathbf{W}^2X_S)^{-1}X_S\mathbf{W}\) the projection matrix. Then
\[
n^{-1}X_j'\hat{\mathbf{W}}(\mathbf{W}\mathbf{w} - \hat{\mathbf{W}}X\hat{\mathbf{w}}) = n^{-1}(X_S\tau_S + \mathbf{E}_j)'\hat{\mathbf{W}}\mathbf{P}_{w,S}^\perp\hat{\mathbf{w}}\mathbf{W}
= n^{-1}\mathbf{E}'_j\mathbf{W}\mathbf{P}_{w,S}^\perp\mathbf{W}\text{diag}(\exp(X\theta/2))\mathbf{e}
= \mathbf{Z}'_j\mathbf{e}.
\]
Conditioned on $X$, we have that

$$\mathbb{P}\left[ \max_{j \in S^c} |Z'_j e| > t \right] \leq 2(p-s) \exp\left( -\frac{t^2}{\max_{j \in S^c} \|Z_j\|_2^2} \right) \tag{56}$$

using Lemma 4 and (15) together with the union bound.

We proceed to bound $\max_{j \in S^c} \|Z_j\|_2^2$. Write

$$Z_j = n^{-1} E'_j (\hat{W} - W) P_{w,S} (\hat{W} - W)^\dagger \text{diag}(\exp(X \theta / 2))$$

$$+ n^{-1} E'_j (\hat{W} - W) P_{w,S}$$

$$+ n^{-1} E'_j W P_{w,S} (\hat{W} - W) \text{diag}(\exp(X \theta / 2))$$

$$+ n^{-1} E'_j W P_{w,S}. \tag{57}$$

Using (48), we have that

$$\|Z_j\|_2 \leq n^{-1} \|E_j\|_2 (\|\hat{W} - W\|_2^2 \bar{\sigma} + 2\|W - W\|_2 + \bar{\sigma})$$

$$\leq \sqrt{3K} (\max_{j \in S} \Sigma_{j(S)}) n^{-1/2} (\|\hat{W} - W\|_2^2 \bar{\sigma} + 2\|W - W\|_2 + \bar{\sigma}) \tag{58}$$

with probability $1 - (p-s) \exp(-2n)$ using Lemma 4 with the union bound. Therefore, we have that

$$\|n^{-1} X'_j \hat{W} (\hat{W} Y - \hat{W} X \hat{\beta}_w)\|_\infty \leq \sqrt{\max_{j \in S^c} \|Z_j\|_2 \log(2(p-s)/\delta)}$$

$$= \mathcal{O}(\sqrt{\bar{\sigma} \log(p-s)n^{-1/2}}).$$

This concludes the proof of the first part.

Second part of Theorem follows similarly to the proof of Theorem\[\square\] We have already shown

$$\hat{\beta}_{w,S} - \beta_{w,S} = n^{-1} D_{SS}^{-1} X'_S W e + o_p(1),$$

and the rest follows as in Theorem\[\square\]
