(Dated: November 25, 2010)

We study the single transverse spin asymmetries in the single inclusive particle production within the framework of the generalized parton model (GPM). By carefully analyzing the initial- and final-state interactions, we include the process-dependence of the Sivers functions into the GPM formalism. The modified GPM formalism has a close connection with the collinear twist-3 approach. Within the new formalism, we make predictions for inclusive $\pi^0$ and direct photon productions at RHIC energies. We find the predictions are opposite to those in the conventional GPM approach.

I. INTRODUCTION

Single transverse-spin asymmetries (SSAs) in both high energy lepton-hadron and hadronic scattering processes have attracted considerable attention from both experimental and theoretical communities over the years. Generally, defined as $A_N \equiv (\sigma(S_\perp) - \sigma(-S_\perp))/\left(\sigma(S_\perp) + \sigma(-S_\perp)\right)$, the ratio of the difference and the sum of the cross sections when the hadron’s spin vector $S_\perp$ is flipped, SSAs have been consistently observed in various experiments at different collision energies.

Much theoretical progress has been achieved in the recent years. An important realization is the crucial role of the initial- and final-state interactions between the struck parton and the target remnant, which provide the necessary phases that leads to the non-vanishing SSAs. These interactions can be accounted for by including the appropriate color gauge links in the gauge invariant transverse momentum dependent (TMD) parton distribution functions (PDFs). An important example is the quark Sivers function, which represents the distribution of unpolarized quarks in a transversely polarized nucleon, through a correlation between the quark’s transverse momentum and the nucleon polarization vector. They are believed to be (partially) responsible for the SSAs observed in the experiments.

The details of the initial- and final-state interactions depend on the scattering process, thus the form of the gauge link in the Sivers function is process dependent. As a result, the Sivers function itself is non-universal. For example, it is the difference between the final-state interactions (FSIs) in semi-inclusive deep inelastic scattering (SIDIS) and the initial-state interactions (ISIs) in Drell-Yan (DY) process in proton collision that leads to an opposite sign in the Sivers function probed in these two processes. For hadron production in proton collision, typically the Sivers function has a more complicated relation relative to those probed in SIDIS and DY processes; that is, there are only FSIs (ISIs) in the SIDIS (DY) process, while both ISIs and FSIs exist for single inclusive particle production.

The SSAs for inclusive single particle production in hadronic collisions are among the earliest processes studied in experiments, starting from the fixed-target experiments in 1980s. Recently the experiments at Relativistic Heavy Ion Collider (RHIC) have also measured the SSAs of inclusive hadron production in proton collisions over a wide range of energies. Theoretically a QCD collinear factorization formalism at next-to-leading-power (twist-3) has been developed and been used in the phenomenological studies. Alternatively, a more phenomenological approach has also been formulated in the context of generalized parton model (GPM), with the inclusion of spin and transverse momentum effects. In this approach TMD factorization is assumed as a reasonable starting point; at the same time, the leading twist TMD distributions (Sivers functions) are assumed to be universal (process-independent), thus the same as those in SIDIS process.

In this paper we formulate the SSAs in inclusive single particle production within the framework of the GPM approach. However, instead of using a process-independent Sivers function, we will carefully examine the initial- and final-state interaction effects, and determine the process-dependent Sivers function. Further we find one can shift the...
process-dependence of the Sivers function to the squared hard partonic scattering amplitude under one-gluon exchange approximation, and these modified hard parts are very similar in form as those in the twist-3 collinear approach \cite{19} in terms of Mandelstam variables $s, t, u$ (as we will demonstrate). This suggests a close connection between this modified GPM formalism and the twist-3 approach. However, it is important to mention that Mandelstam variables $s, t, u$ are themselves a function of partonic intrinsic transverse momentum in the GPM approach. We comment on these issues at the end of Section II, where we also show the modified GPM formalism can reproduce the twist-3 process-dependence of the Sivers function to the squared hard partonic scattering amplitude under one-gluon exchange approximation, and these modified hard parts are very similar in form as those in the twist-3 collinear approach \cite{15}.

The rest of the paper is organized as follows: In Sec. II, we introduce the GPM approach, demonstrate how to formulate the ISI and FSI effects, and discuss the connection to the twist-3 collinear factorization approach. In Sec. III, we estimate the FSI effects, and compare our predictions with those from the conventional GPM approach. We conclude our paper in Sec. IV.

II. INITIAL- AND FINAL-STATE INTERACTIONS IN SINGLE INCLUSIVE PARTICLE PRODUCTION

In this section, we introduce the basic ideas and assumptions of the GPM approach. Then we discuss how to formulate the initial- and final-state interactions for single inclusive particle production. Within the same framework of GPM approach, we thus derive a new formalism for the SSAs of single inclusive particle production, with the process-dependence of the Sivers function taken into account.

A. Generalized Parton Model

The generalized parton model was introduced by Feynman and collaborators \cite{23} as a generalization of the usual collinear pQCD approach. It was adapted and used to describe the SSAs for inclusive particle production \cite{17–19}, which has had considerable phenomenological success \cite{18}. According to this approach, for the inclusive production of large $P_{hT}$ hadrons (or photons), $A^I(P_A) + B(P_B) \rightarrow h(P_h) + X$, the differential cross section can be written as

$$E_h \frac{d\sigma}{d^3P_h} = \frac{\alpha^2}{S} \sum_{a,b,c} \int \frac{dx_a}{x_a} \frac{d^2k_{aT}f_{a/A'}(x_a, \vec{k}_{aT})}{d^2k_{bT}f_{b/B}(x_b, \vec{k}_{bT})} \int \frac{d\zeta_c}{\zeta_c} \frac{D_{h/c}(\zeta_c)H_{h\rightarrow h}(\hat{s}, \hat{t}, \hat{u})\delta(\hat{s} + \hat{t} + \hat{u})}{\zeta_c},$$

(1)

where $S = (P_A + P_B)^2$, $f_{a/A'}(x_a, \vec{k}_{aT})$ is the TMD parton distribution functions with $k_{aT}$ the intrinsic transverse momentum of parton $a$ with respect to the light-cone direction of hadron $A$, and $D_{h/c}(\zeta_c)$ is the fragmentation function. Since we will only consider the SSAs generated from the parton distribution functions in this paper, we have neglected the $t, u$-dependence in the fragmentation function. $H_{h\rightarrow h}(\hat{s}, \hat{t}, \hat{u})$ is the hard part coefficients with $\hat{s}, \hat{t}, \hat{u}$ the usual partonic Mandelstam variables. Eq. (1) can also be used to describe direct photon production, in which one replaces the fragmentation function $D_{h/c}(\zeta_c)$ by $\delta(\zeta_c - 1)$, and $\alpha^2$ by $\alpha_{em}^2 \alpha_s$.

To clearly specify the kinematics, we consider the center-of-mass frame of the two initial hadrons, in which one has $P_A^\mu = \sqrt{S}/2 \bar{n}^\mu$ and $P_B^\mu = \sqrt{S}/2 n^\mu$, with $\bar{n}^\mu = [1^+, 0^-, 0_1, 0_2]$ and $n^\mu = [0^+, 1^-, 0_1, 0_2]$ in light-cone components. For future convenience we also define the hadronic Mandelstam invariants, $T = (P_A - P_h)^2$ and $U = (P_B - P_h)^2$. Additionally, the momenta of the partons in the partonic process $a(p_a) + b(p_b) \rightarrow c(p_c) + d(p_d)$ can be written as

$$p_a^\mu = \left[ x_a \sqrt{S} \frac{k^2_{aT}}{2S}, \frac{k^2_{aT}}{x_a \sqrt{S}}, \vec{\bar{k}}_{aT} \right], \quad p_b^\mu = \left[ \frac{k^2_{bT}}{x_b \sqrt{2S}}, x_b \sqrt{\frac{S}{2}}, \vec{k}_{bT} \right],$$

(2)

where the momentum of parton $c$ is related to the final hadron as: $p_c = P_h/\zeta_c$.

To study the SSAs, the PDFs $f_{a/A'}(x_a, \vec{k}_{aT})$ in the transversely polarized hadron $A$ can be expanded as \cite{17–20}

$$f_{a/A'}(x_a, \vec{k}_{aT}) = f_{a/A}(x_a, k^2_{aT}) + f_{1T}^{aA}(x_a, k^2_{aT}) \frac{\epsilon_{aT} S_A \bar{n}}{M},$$

(3)

where $S_A$ is the transverse polarization vector, $M$ is the mass of hadron $A$, $f_{a/A}(x_a, k^2_{aT})$ is the spin-averaged PDFs, and $f_{1T}^{aA}(x_a, k^2_{aT})$ is the Sivers functions. Thus in GPM approach, the spin-averaged differential cross section is given by Eq. (1) with $f_{a/A'}(x_a, \vec{k}_{aT})$ replaced by $f_{a/A}(x_a, k^2_{aT})$, while the spin-dependent cross section is given by

$$E_h \frac{d^2\sigma}{d^2P_h} = \frac{\alpha^2}{S} \sum_{a,b,c} \int \frac{dx_a}{x_a} \frac{d^2k_{aT}f_{1T}^{aA}(x_a, k^2_{aT})}{d^2k_{bT}f_{b/B}(x_b, k^2_{bT})} \epsilon_{aT} S_A \bar{n} M \int \frac{d\zeta_c}{\zeta_c} \frac{D_{h/c}(\zeta_c)\delta(\zeta_c - 1)}{\zeta_c},$$

(4)
corresponding partonic scattering

For the SIDIS process and the initial-state interaction for DY process. To the leading order (one-gluon exchange), they are shown in Fig. 1.

The struck parton and the spectators from the polarized nucleon through the gluon exchange. Thus by analyzing the existence of the Sivers function in the polarized nucleon relies on the initial- and final-state interactions between gauge link (in an expansion of the coupling $g$) is the color index for this gluon. The eikonal part (the term in the bracket) is the first order contribution of the

\[ \frac{d\sigma}{dx} = \alpha_s^2 \sum_{a,b,c} \int \frac{dx_a}{x_a} (\frac{d^2k_a}{2\pi})_{\perp} f_{1_T}^{a,ab-\rightarrow cd}(x_a, k_{aT}^2) \frac{\epsilon_{k_aT}^a S_{\perp aT}}{M} \int \frac{dx_b}{x_b} d^2k_b f_{h/B}(x_b, k_{bT}^2) \]

in which a \textit{process-dependent Sivers function} denoted as $f_{1_T}^{a,ab-\rightarrow cd}(x_a, k_{aT}^2)$ is used rather than that from SIDIS $f_{1_T}^{\perp a,\text{SIDIS}}(x_a, k_{aT}^2)$ as in the conventional GPM approach.

B. Initial- and final-state interactions

In this subsection, we will discuss how to formulate the initial- and final-state interactions. The crucial point is that the existence of the Sivers function in the polarized nucleon relies on the initial- and final-state interactions between the struck parton and the spectators from the polarized nucleon through the gluon exchange. Thus by analyzing these interactions, one can determine the process dependent Sivers function $f_{1_T}^{a,ab-\rightarrow cd}(x_a, k_{aT}^2)$ to be used for the corresponding partonic scattering $ab \rightarrow cd$. We start with the classic examples: the final-state interaction in SIDIS, and the initial-state interaction for DY process. To the leading order (one-gluon exchange), they are shown in Fig. 1.

For the SIDIS process $e(\ell) + p(P_A, S_T) \rightarrow e(\ell') + h + X$ with $Q^2 = -q^2 = -((\ell' - \ell)^2)$, under the eikonal approximation,

\[ p_a \rightarrow \gamma_a(p_a) \rightarrow T^a \]

where the gamma matrix $\gamma^-$ appears because of the interaction with a longitudinal polarized gluon ($\sim A^+$), and $a$ is the color index for this gluon. The eikonal part (the term in the bracket) is the first order contribution of the gauge link (in an expansion of the coupling $g$) in the definition of a gauge-invariant TMD PDFs in SIDIS process, see Fig. 2(a). The imaginary part of the eikonal propagator $1/(-k^+ + i\epsilon)$ provides the necessary phase for the SSAs.

On the other hand, for DY process, the initial-state interaction (as in Fig. 1(right)) leads to

\[ \bar{v}(p_b)(-ig)\gamma^- T^a \frac{-i(p_b + \hat{k})}{(p_b + \hat{k})^2 + i\epsilon} \approx \bar{v}(p_b) \frac{g}{-k^+ - i\epsilon} T^a, \]

where $\gamma^-$ appears because of the interaction with a longitudinal polarized gluon ($\sim A^+$), and $a$ is the color index for this gluon. The eikonal part (the term in the bracket) is the first order contribution of the gauge link (in an expansion of the coupling $g$) in the definition of a gauge-invariant TMD PDFs in SIDIS process, see Fig. 2(a). The imaginary part of the eikonal propagator $1/(-k^+ + i\epsilon)$ provides the necessary phase for the SSAs.

On the other hand, for DY process, the initial-state interaction (as in Fig. 1(right)) leads to

\[ \bar{v}(p_b)(-ig)\gamma^- T^a \frac{-i(p_b + \hat{k})}{(p_b + \hat{k})^2 + i\epsilon} \approx \bar{v}(p_b) \frac{g}{-k^+ - i\epsilon} T^a, \]

the final-state interaction (as in Fig. 1(left)) leads to

\[ \bar{u}(p_c)(-ig)\gamma^- T^a \frac{i(p_c - \hat{k})}{(p_c - \hat{k})^2 + i\epsilon} \approx \bar{u}(p_c) \frac{g}{k^+ + i\epsilon} T^a, \]
which has the same real part and opposite imaginary part compared to SIDIS process. This leads to the fact that the spin-averaged TMD PDFs are the same, while the Sivers function will be opposite in SIDIS and DY processes. This conclusion can be generalized to all order, and has been proven to be true using parity and time-reversal invariant arguments \[6, 8\].

Now let us turn to the case for inclusive single particle production in hadronic collisions, in which 2 → 2 partonic scattering is the leading order contribution, where both initial- and final-state interactions contribute. We will start with a simple example: \(qq' \rightarrow qq'\). Here the initial-quark \(q\) is from the polarized nucleon, and the final-quark \(q\) fragments to the final-state hadron. The one-gluon exchange approximation for the initial- and final-state interactions are shown in Fig. 3. Under the eikonal approximation, for ISI Fig. 3(a),

\[
\frac{i(p_b + k)}{(p_b + k)^2 + i\epsilon}(-ig)\gamma^a T^a u(p_b) = \left[\frac{-g}{-k^+ + i\epsilon} T^a\right] u(p_b).
\]

Likewise, for the FSI Fig. 3(b), we have

\[
\bar{u}(p_c)(-ig)\gamma^a T^a \left[\frac{g}{g - k^+ + i\epsilon} T^a\right] = \bar{u}(p_c) u(p_b).
\]

Thus both interactions contribute to the phase \(-i\pi \delta(k^+)\), which is the same as in the SIDIS process as in Eq. (7). However, they will have different color flow. To extract the extra color factors for Fig. 3(a) and (b) as compared to the usual \(qq' \rightarrow qq'\) without gluon attachments, we resort to the method developed in \[14, 15, 26\]. We obtain the color factors \(C_I, C_{F_c}\) for initial (final)-state interaction

\[
C_I = -\frac{1}{2N_c^2}, \quad C_{F_c} = -\frac{1}{4N_c^2},
\]

while the color factors for unpolarized cross section is given by

\[
C_u = \frac{N_c^2 - 1}{4N_c^2}.
\]

In other words, the Sivers function in \(qq' \rightarrow qq'\) should be the one as shown in Fig. 4, which comes from the sum of the ISIs and FSIs with the corresponding color factors \(C_I\) and \(C_{F_c}\) respectively. Thus by comparing the imaginary part of the eikonal propagators in Eq. (7) for SIDIS and those in Eqs. (9) and (10) for ISI and FSI for \(qq' \rightarrow qq'\), we immediately find the Sivers function probed in \(qq' \rightarrow qq'\) process is related to those in SIDIS as follows

\[
f_{1T}^{\perp_a, qq' \rightarrow qq'} = \frac{C_I + C_{F_c}}{C_u} f_{1T}^{\perp_a, \text{SIDIS}}.
\]
Thus in the GPM model, using the process dependent Sivers function, one should replace

\[ f_{1T}^{\perp a,\text{SIDIS}} H_{qq'\rightarrow qq}^U \equiv f_{1T}^{\perp a,\text{SIDIS}} [C_u h_{qq'\rightarrow qq}], \tag{14} \]

by the following form

\[ f_{1T}^{\perp a,qq'\rightarrow qq'} H_{qq'\rightarrow qq}^U = \frac{C_I + C_F}{C_u} f_{1T}^{\perp a,\text{SIDIS}} H_{qq'\rightarrow qq}^U = f_{1T}^{\perp a,\text{SIDIS}} [C_I h_{qq'\rightarrow qq} + C_F h_{qq'\rightarrow qq'}], \tag{15} \]

where \( h_{qq'\rightarrow qq'} \) is the partonic cross section without color factors included. For \( qq' \rightarrow qq' \), one has

\[ h_{qq'\rightarrow qq'} = \frac{2 \hat{s}^2 + \hat{u}^2}{t^2}. \tag{16} \]

Alternatively one can use \( f_{1T}^{\perp a,\text{SIDIS}} \) for the single inclusive particle production while accounting for the process-dependence of the Sivers function, by shifting the process-dependence to the hard parts. In other words, instead of using \( H_{qq'\rightarrow qq'}^U \) in Eq. (4) for the spin-dependent cross section, one should use

\[ H_{qq'\rightarrow qq'}^{\text{Inc}} \\equiv H_{qq'\rightarrow qq'}^{\text{Inc}-I} + H_{qq'\rightarrow qq'}^{\text{Inc}-F}, \tag{17} \]

where

\[ H_{qq'\rightarrow qq'}^{\text{Inc}-I} = C_I h_{qq'\rightarrow qq'}, \quad H_{qq'\rightarrow qq'}^{\text{Inc}-F} = C_F h_{qq'\rightarrow qq'}, \tag{18} \]

are the corresponding hard parts related to initial- and final-state interactions, respectively.

There are many other partonic processes contributing to the single inclusive particle production. Similar to the analysis in \( qq' \rightarrow qq' \), one needs to analyze each individual Feynman diagram accordingly, carefully moving the extra factors (process-dependence) from the corresponding Sivers function to the hard parts, thus obtaining \( H_{ab\rightarrow cd}^{\text{Inc}-I} \) and \( H_{ab\rightarrow cd}^{\text{Inc}-F} \) for every channel. The modified formalism will be given in the next subsection.

There are some comments to our results presented to this point: in particular those displayed in Fig. 4. It looks like Figs. 3(a), (b) can be factorized into a convolution of Sivers function and a hard part function as shown in Fig. 4. However, this is not a TMD factorization in the strict sense. Currently TMD factorization theorems have been established for both SIDIS and DY processes \[24, 25\]. To the order we are studying, this means, the one-gluon exchange diagram for SIDIS in Fig. 1 can be factorized into a convolution of a Sivers function \( f_{1T}^{\perp a, \text{SIDIS}}(x_a, k_{aT}^2) \) and a hard part function \( H(Q) \), as shown in Fig. 2. Here all the soft physics (those depending on \( k_{aT} \)) has been absorbed into the Sivers function \( f_{1T}^{\perp a, \text{SIDIS}}(x_a, k_{aT}^2) \), and the hard part function \( H(Q) \) only depends on the hard scale \( Q \), not \( k_{aT} \). On the other hand, for \( qq' \rightarrow qq' \), we write the corresponding diagram Fig. 3(a) into a similar form: a product of a Sivers function \( f_{1T}^{\perp a,qq'\rightarrow qq'}(x_a, k_{aT}^2) \) and a hard part function \( H_{qq'\rightarrow qq'}(\hat{s}, \hat{t}, \hat{u}) \), as shown in Fig. 4. But as we will comment later, besides the \( k_{aT} \) dependence from the Sivers function, one will also need to keep the \( k_{aT} \) dependence in the hard part functions \( H_{qq'\rightarrow qq'} \), without which the SSAs will vanish in both the conventional GPM and this modified GPM formalism. Even though this is not a TMD factorization, one hopes this formalism is a reasonable approximation. There are two reasons to suggest this might be the case. First of all, from phenomenological point of view, this formalism had some success \[18\]. Secondly, as we will show in Section 11 this formalism has a connection with the well-established collinear twist-3 approach \[15\]. In this respect, our identification of the color factors with the hard cross-sections is reminiscent of the results of the twist 3 approach (see in particular \[15\]). Indeed we will see that upon calculating all partonic processes that contribute from each channel, they have the same form in terms of Mandelstam variables \( \hat{s}, \hat{t}, \hat{u} \), as compared to those in the twist-3 collinear factorization approach \[15\] (up to a prefactor associated with final state interactions).
To close this subsection, we want to point out the following important fact: the interaction with the unobserved particle (the quark $q'$ for $qq' \rightarrow qq'$) vanishes after summing different cut diagrams \([14, 15, 27]\). To see this clearly, we have for Figs. 3(c) and 3(d)

\[
\frac{1}{(p_d - k)^2 + i\epsilon} \delta(p_d^2) \rightarrow -i\pi \delta((p_d - k)^2)\delta(p_d^2), \quad \text{and} \quad \frac{1}{p_d^2 - i\epsilon} \delta((p_d - k)^2) \rightarrow +i\pi \delta((p_d - k)^2)\delta(p_d^2),
\]

(19)

respectively. Since the remaining parts of the scattering amplitudes for these two diagrams are exactly the same except for the above pole contributions which are opposite to each other, the contribution from the unobserved particle vanishes. This could also be used to explain why the inclusive DIS process, the SSA vanishes. As shown in Fig. 11(left), we don’t observe the final-state quark for the inclusive DIS process, thus the contribution from the cut to the left and to the right will cancel which results in a vanishing asymmetry.

We want to emphasize that the above analysis holds true only under one-gluon exchange approximation. Going beyond one-gluon exchange, the Sivers functions are typically more complicated, there seems no simple relation (as extra color factors) to those in the SIDIS process \([28]\).

C. Single inclusive hadron production

Now after carefully taking into account both initial- and final-state interactions, the more appropriate GPM formalism for spin-dependent cross section should be written as

\[
E_k \frac{d\Delta \sigma}{d^3p_h} = \frac{\alpha_s^2}{\hat{S}} \sum_{a,b,c} \int \frac{d^3x_a}{x_a} d^2k_a f_{aT}^{La,SIDIS}(x_a, k_a^2) \frac{\epsilon_{aT}^S A_nT}{M} \int \frac{d^3x_b}{x_b} d^2k_b f_{b/B}(x_b, k_b^2) \times \int \frac{dz}{z^2} D_{h/c}(z)c H_{ab\rightarrow c}^{Inc}(\hat{s}, \hat{t}, \hat{u}) \delta(\hat{s} + \hat{u}),
\]

(20)

where we have a new hard part function $H_{ab\rightarrow c}^{Inc}$ instead of $H_{ab\rightarrow c}^{U}$ used in the conventional GPM approach. Here the process dependence in the Sivers function has been absorbed into $H_{ab\rightarrow c}^{Inc}$, which can be written as

\[
H_{ab\rightarrow c}^{Inc}(\hat{s}, \hat{t}, \hat{u}) = H_{ab\rightarrow c}^{Inc-1}(\hat{s}, \hat{t}, \hat{u}) + H_{ab\rightarrow c}^{Inc-F}(\hat{s}, \hat{t}, \hat{u}),
\]

(21)

where $H_{ab\rightarrow c}^{Inc-1}$ and $H_{ab\rightarrow c}^{Inc-F}$ are associated with initial- and final-state interactions, respectively. The contributions for the various contributing partonic subprocesses are given by

\[
H_{qq\rightarrow qq}^{Inc-1} = -H_{qq'\rightarrow qq'}^{Inc-1} = -\frac{N_c^2}{2}\left[\frac{\hat{s}^2 + \hat{u}^2}{t^2}\right], \quad H_{qq'\rightarrow qq'}^{Inc-F} = -H_{qq\rightarrow qq}^{Inc-F} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{u}^2}{t^2}\right],
\]

(22)

\[
H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -\frac{N_c^2}{2}\left[\frac{\hat{s}^2 + \hat{u}^2}{t^2}\right], \quad H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{u}^2}{t^2}\right],
\]

(23)

\[
H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -\frac{1}{N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right], \quad H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -H_{qq'\rightarrow q\bar{q}}^{Inc-F} = \frac{N_c^2}{2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right],
\]

(24)

\[
H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -\frac{1}{N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right], \quad H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -\frac{1}{N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right],
\]

(25)

\[
H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right], \quad H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right],
\]

(26)

\[
H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right], \quad H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right],
\]

(27)

\[
H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -H_{qq'\rightarrow q\bar{q}}^{Inc-1} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right], \quad H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -H_{qq'\rightarrow q\bar{q}}^{Inc-F} = -\frac{1}{2N_c^2}\left[\frac{\hat{s}^2 + \hat{t}^2}{\hat{u}^2}\right],
\]

(28)
However, there are two differences in the formalisms. First, in the twist-3 collinear approach, all the interactions. However, in our modified GPM formalism as in Eq. (21), there is no such factor. This difference can be suggested that there are close connections between our modified GPM formalism and the twist-3 collinear factorization formalism, respectively. However, there are two differences in the formalisms. First, in the twist-3 collinear factorization approach. We explore this potential connection in the next subsection.

As pointed out in the last subsection, it is the linear in $k_{aT}$ dependence from the rest of the integral in Eq. (20) that contributes to the asymmetry. We thus make an expansion and keep only the linear in $k_{aT}$ terms. We will show that the leading term in this expansion has a close connection to the twist-3 collinear factorization formalism.

\[ H_{qg \rightarrow \gamma q}^{\text{inc-F}} = -H_{qg \rightarrow \gamma q}^{\text{inc-F}} = \frac{1}{2N_c^2} \left[ \frac{s^2 + u^2}{t^2} + \frac{N_c^2 - 2}{2N_c^2} \left[ \frac{t^2 + u^2}{s^2} \right]^2 + \frac{1}{N_c^2} \frac{\hat{u}^2}{s t} \right] \]

\[ H_{qg \rightarrow \gamma q}^{\text{inc-1}} = -H_{qg \rightarrow \gamma q}^{\text{inc-1}} = \frac{N_c^2 - 2}{2N_c^2} \left[ \frac{s^2 + u^2}{t^2} + \frac{1}{2N_c^2} \left[ \frac{t^2 + u^2}{s^2} \right] + \frac{1}{N_c^2} \frac{\hat{u}^2}{s u} \right] \]

\[ H_{qg \rightarrow \gamma g}^{\text{inc-F}} = -H_{qg \rightarrow \gamma q}^{\text{inc-F}} = \frac{1}{2N_c^2 (N_c^2 - 1)} \left[ -\frac{s}{u} + \frac{u}{s} \right] \frac{1}{N_c^2 - 1} \left[ \frac{s^2 + u^2}{t^2} \right] \]

\[ H_{qg \rightarrow \gamma g}^{\text{inc-1}} = -H_{qg \rightarrow \gamma g}^{\text{inc-1}} = \frac{1}{2N_c^2 (N_c^2 - 1)} \left[ -\frac{s}{u} + \frac{u}{s} \right] \frac{1}{N_c^2 - 1} \left[ \frac{s^2 + u^2}{t^2} \right] \]

\[ H_{qg \rightarrow \gamma g}^{\text{inc-F}} = -H_{qg \rightarrow \gamma g}^{\text{inc-F}} = \frac{1}{2N_c^2} \left[ \frac{\hat{u}}{u} + \frac{\hat{t}}{u} \right] + \frac{N_c}{2} \left[ \frac{t^2 + u^2}{s^2} - \frac{1}{N_c^2} \right] \]

\[ H_{qg \rightarrow \gamma g}^{\text{inc-1}} = -H_{qg \rightarrow \gamma g}^{\text{inc-1}} = \frac{1}{2N_c^2} \left[ \frac{\hat{u}}{u} + \frac{\hat{t}}{u} \right] + \frac{N_c}{2} \left[ \frac{t^2 + u^2}{s^2} - \frac{1}{N_c^2} \right] \]

We also calculate the corresponding hard part functions for direct photon production, and they are given by

\[ H_{qg \rightarrow \gamma q}^{\text{inc}} = -H_{qg \rightarrow \gamma q}^{\text{inc}} = -\frac{N_c}{N_c^2 - 1} \left[ \frac{-\hat{s}}{\hat{u} - \hat{s}} \right] \frac{1}{N_c} \left[ \frac{\hat{s}^2 + \hat{u}^2}{\hat{t}} \right], \quad H_{qg \rightarrow \gamma g}^{\text{inc}} = -H_{qg \rightarrow \gamma g}^{\text{inc}} = \frac{1}{N_c^2} \left[ \frac{\hat{t}}{u} + \frac{\hat{u}}{t} \right] \]

Here again we note that all these hard part functions have the same form in terms of Mandelstam variables $\hat{s}$, $\hat{t}$, $\hat{u}$, compared to those in the twist-3 collinear factorization approach. \[ H_{ab \rightarrow c}^{\text{inc-1}} \] and \[ H_{ab \rightarrow c}^{\text{inc-F}} \] have the same functional form as the corresponding ones \[ H_{ab \rightarrow c}^{\text{twist-3-1}} \] and \[ H_{ab \rightarrow c}^{\text{twist-3-F}} \] (defined below) in the twist-3 collinear factorization formalism, respectively. However, there are two differences in the formalisms. First, in the twist-3 collinear approach, the hard part functions are given by

\[ H_{ab \rightarrow c}^{\text{twist-3-1}}(\hat{s}, \hat{t}, \hat{u}) = H_{ab \rightarrow c}^{\text{twist-3-1}}(\hat{s}, \hat{t}, \hat{u}) + H_{ab \rightarrow c}^{\text{twist-3-F}}(\hat{s}, \hat{t}, \hat{u}) \left( 1 + \frac{\hat{u}}{\hat{t}} \right) \]

i.e., there is an extra factor \((1 + \frac{\hat{u}}{\hat{t}})\) accompanying the hard part functions \(H_{ab \rightarrow c}^{\text{twist-3-F}}\) associated with final state interactions. However, in our modified GPM formalism as in Eq. (21), there is no such factor. This difference can be traced back to the eikonal approximation we are using, see, e.g., Eq. (10), where we only keep the pole contribution $-k^+ + i\epsilon$ in the denominator under this approximation. However, there is an extra term linear in $k_{aT} \cdot k_{bT}$ which exists in the twist-3 collinear factorization formalism. This leads to the extra factor \((1 + \frac{\hat{u}}{\hat{t}})\) for the final-state interaction contribution (for details, see Ref. [15]). Second, in the twist-3 collinear factorization approach, all the parton momenta are collinear to the corresponding hadrons, thus \(s, t, u\) does not depend on the parton intrinsic transverse momentum. On the other hand, in the GPM approach the parton momenta involve intrinsic transverse momentum, thus \(s, t, u\) all depend on the the parton transverse momentum, $k_{aT}$ and $k_{bT}$. In fact, because of the existence of the linear $k_{aT}$-dependence in $e^{k_{aT} S_a n_a}$, one has to keep another linear $k_{aT}$-dependence from the rest of the integrand in Eq. (20), otherwise the integral over $d^2k_{aT}$ vanishes. In other words, it is the linear in $k_{aT}$ term in the hard part functions $H_{ab \rightarrow c}^{\text{inc}}(s, t, u)$ and $\delta(\hat{s} + \hat{t} + \hat{u})$ that contributes to the asymmetry. Even with these two differences, the similarities in terms of $\hat{s}, \hat{t}, \hat{u}$ suggest that there are close connections between our modified GPM formalism and the twist-3 collinear factorization approach. We explore this potential connection in the next subsection.

**D. Connection to the twist-3 collinear factorization formalism**

As pointed out in the last subsection, it is the linear in $k_{aT}$ dependence from the rest of the integral in Eq. (20) that contributes to the asymmetry. We thus make an expansion and keep only the linear in $k_{aT}$ terms. We will show that the leading term in this expansion has a close connection to the twist-3 collinear factorization formalism.
We start by specifying the partonic kinematics. Keeping the linear in $k_{aT}$ terms and dropping all the $k_{bT}$-dependence we have $p_h^a \approx x_a P_A^u + k_{aT}$ and $p_h^b \approx x_b P_B^u$, thus

$$\hat{s} \approx x_a x_b S, \quad \hat{t} \approx \frac{x_a}{z_c} T - \frac{2 P_{hT} \cdot k_{aT}}{z_c}, \quad \hat{u} = \frac{x_b}{z_c} U.$$  \hspace{1cm} (36)

Thus we can write the $\delta$-function as

$$\delta(\hat{s} + \hat{t} + \hat{u}) = \frac{1}{x_b S + T/z_c} \delta \left( x_a - x - \frac{2 P_{hT} \cdot k_{aT}}{z_c x_b S + T} \right) \quad \text{where,} \quad x_a = x + \frac{2 P_{hT} \cdot k_{aT}}{z_c x_b S + T},$$  \hspace{1cm} (37)

and $x = -x_b U/(z_c x_b S + T)$ is independent of $k_{aT}$. Now performing the integrate over $x_a$ in Eq. (21) and using the $\delta$-function we get,

$$E_h \frac{d\Delta \sigma}{d^3 P_h} = \frac{\alpha_s^2}{S} \sum_{a,b,c} \int d^2 k_{aT} \frac{e^{k_{aT} S A n n}}{M} \frac{1}{x_a} f_{1a,SIDIS}^{\perp}(x_a, k_{aT}) \int \frac{d x_b}{x_b} f_{b/B}(x_b) \times \left[ \frac{d z_c}{x_c} D_{h/c}(z_c) H_{ab-c}^{inc}(\hat{s}, \hat{t}, \hat{u}) \frac{1}{x_b S + T/z_c} \right]_{x_a = x + 2 P_{hT} \cdot k_{aT} / z_c x_b S + T}.$$  \hspace{1cm} (38)

After replacing $x_a$ as above, one has

$$\hat{s} = \hat{s} - \frac{\hat{s}}{\hat{u}} 2 P_{hT} \cdot k_{aT} / z_c, \quad \hat{t} = \hat{t} + \frac{\hat{s}}{\hat{u}} 2 P_{hT} \cdot k_{aT} / z_c, \quad \hat{u} = \hat{u},$$  \hspace{1cm} (39)

where $\hat{s} = x_b S, \hat{t} = x T / z_c, \hat{u} = x_b U / z_c$ and they are all independent of $k_{aT}$. Note $\hat{s} + \hat{t} + \hat{u} = 0$ implies $\hat{s} + \hat{t} + \hat{u} = 0$. Now besides the $e^{k_{aT} S A n n}$, the linear in $k_{aT}$ contributions in Eq. (38) can come from, either (a) $x_a$-dependence in $f_{1a,SIDIS}^{\perp}(x_a, k_{aT}^2)$, or (b) the $\hat{s}$- and $\hat{t}$-dependence in $H_{ab-c}^{inc}(\hat{s}, \hat{t}, \hat{u})$. This is because $x_a, \hat{s}$, and $\hat{t}$ are the only terms in Eq. (38) which depend linearly in $k_{aT}$. We now make $k_{aT}$ expansion one by one. First for contribution (a), since

$$\frac{\partial x_a}{\partial k_{aT}} = \frac{2 P_{hT a}}{z_c x_b S + T},$$  \hspace{1cm} (40)

to the linear term in $k_{aT}$, we have

$$E_h \frac{d\Delta \sigma^{(a)}}{d^3 P_h} = \frac{\alpha_s^2}{S} \sum_{a,b,c} \int d^2 k_{aT} \frac{e^{k_{aT} S A n n}}{M} \frac{2 P_{hT a}}{z_c x_b S + T} \frac{d}{d x_a} \left[ f_{1a,SIDIS}^{\perp}(x_a, k_{aT}) \right]_{x_a \rightarrow x} \int \frac{d x_b}{x_b} f_{b/B}(x_b) \times \left[ \frac{d z_c}{x_c} D_{h/c}(z_c) H_{ab-c}^{inc}(\hat{s}, \hat{t}, \hat{u}) \frac{1}{x_b S + T/z_c} \right]_{x_a = x + 2 P_{hT} \cdot k_{aT} / z_c x_b S + T},$$  \hspace{1cm} (41)

where we have dropped all $k_{aT}$ dependence in $H_{ab-c}^{inc}$, thus replacing the $k_{aT}$-dependent $\hat{s}, \hat{t}, \hat{u}$ by the $k_{aT}$-independent $\hat{s}, \hat{t}, \hat{u}$ in $H_{ab-c}^{inc}$. Then using

$$\int d^2 k_{aT} k_{aT}^\beta k_{aT}^\alpha f_{1T}^{inc}(x_a, k_{aT}^2) = -\frac{1}{2} \int d^2 k_{aT} \epsilon^{\alpha \beta \gamma} | \vec{k}_{aT} |^2 f_{1T}^{inc}(x_a, k_{aT}^2),$$  \hspace{1cm} (42)

and the relation between the Sivers function and the Efremov-Teryaev-Qiu-Sterman function $T_{a,F}(x, x)$ \[^{[S]}\]

$$T_{a,F}(x, x) = -\frac{1}{M} \int d^2 k_{aT} | \vec{k}_{aT} |^2 f_{1T}^{inc}(x, k_{aT}^2),$$  \hspace{1cm} (43)

one can rewrite Eq. (41) as

$$E_h \frac{d\Delta \sigma^{(a)}}{d^3 P_h} = \frac{\alpha_s^2}{S} \sum_{a,b,c} \int \frac{d z_c}{x_c} D_{h/c}(z_c) \frac{P_{hT} S A n n}{z_c} \left[ T_{a,F}(x, x) - \frac{d}{d x} T_{a,F}(x, x) \right] \int \frac{d x_b}{x_b} f_{b/B}(x_b) H_{ab-c}^{inc}(\hat{s}, \hat{t}, \hat{u}) \frac{1}{x_b S + T/z_c}.$$  \hspace{1cm} (44)

We observe that this form is the same as that in the twist-3 collinear factorization approach. In particular, note that there is no $k_{aT}$-dependence in the hard part functions $H_{ab-c}^{inc}$. The difference to the twist-3 collinear factorization formalism \[^{[12]}\] (as mentioned above) is the extra factor $(1 + \hat{u}/\hat{t})$ accompanying the hard part functions associated with final-state interactions, see Eqs. (21) and (35).
However, in our modified GPM formalism, we have another contribution from (b), due to the \(k_{aT}\)-dependence from \(H_{ab\rightarrow c}^{inc}(\hat{s}, \hat{t}, \hat{u})\) in Eq. (43). Let’s now study this contribution (b). As is explicit in Eq. (43), \(\hat{u}\) is independent of \(k_{aT}\) while both \(\hat{s}\) and \(\hat{t}\) depend on \(k_{aT}\). Since \(\hat{s} + \hat{t} + \hat{u} = 0\), one could then set \(\hat{t} = -\hat{s} - \hat{u}\) in \(H_{ab\rightarrow c}^{inc}\) and then expand only \(\hat{s}\) in \(k_{aT}\). That is,

\[
\left. \frac{\partial}{\partial k_{aT}^a} H_{ab\rightarrow c}^{inc}(\hat{s}, \hat{t}, \hat{u}) \right|_{k_{aT}\rightarrow 0} = \left. \frac{\partial \hat{s}}{\partial k_{aT}^a} \frac{\partial \hat{t}}{\partial \hat{s}} H_{ab\rightarrow c}^{inc}(\hat{s}, -\hat{s} - \hat{u}, \hat{u}) \right|_{k_{aT}\rightarrow 0} = \frac{2s}{u} \frac{P_{hT}}{\hat{u}} \frac{\partial}{\partial 3} H_{ab\rightarrow c}^{inc}(\hat{s}, -\hat{s} - \hat{u}, \hat{u}).
\] (45)

Then we have the contribution (b)

\[
E_h \frac{d\Delta\sigma^{(b)}}{d^3P_h} = \frac{2s}{S} \sum_{a,b,c} \int \frac{dz}{z_c} D_{h/c}(z_c) \hat{P}_{hT}^{S_A} \frac{1}{\hat{u}} \left[ T_{a,F}(x, x) \int \frac{dz_b}{\hat{u}} j_{b/B}(x_b) \left[ -\frac{\partial}{\partial \hat{s}} H_{ab\rightarrow c}^{inc}(\hat{s}, -\hat{s} - \hat{u}, \hat{u}) \right] \right] \frac{1}{x_b S + T/z_c}.
\] (46)

Thus to the leading order (linear in \(k_{aT}\) terms), the spin-dependent cross section in our modified GPM formalism can be written as

\[
E_h \frac{d\Delta\sigma}{d^3P_h} = E_h \frac{d\Delta\sigma^{(a)}}{d^3P_h} + E_h \frac{d\Delta\sigma^{(b)}}{d^3P_h},
\] (47)

with the contributions (a) and (b) given by Eqs. (44) and (45), respectively. The term (a) almost reproduces the twist-3 collinear factorization formalism in Ref. [15] modulating the extra factor \((1 + \hat{u}/\hat{t})\) associated with final state interactions, for which the origin of the difference is understood in last subsection. On the other hand, for the extra term (b), theoretically how to interpret this “mismatch” and why the term (b) does not appear in the usual twist-3 collinear factorization formalism deserves further investigation [29]. Here it is important to note, from the phenomenological perspective, as already shown in [15], the derivative of the correlation function \(T_{a,F}(x, x)\) is the dominant contribution to the SSAs, thus we expect the term (b), which contains no derivative, to play a less important role in generating the SSAs compared with term (a). In other words, even though this modified GPM has an extra piece compared with the well-known twist-3 collinear factorization formalism, phenomenologically (numerically) this formalism could give a good approximation to the SSAs. This remains to be confirmed [29] because there is still a difference in term (a) on the extra factor \((1 + \hat{u}/\hat{t})\) associated with the final state interactions between the twist-3 collinear factorization approach and our modified GPM formalism. If this were the case, it will provide further support to the modified GPM approach to the SSAs.

To close this section, we want to emphasize that the contribution calculated in Ref. [15] only comes from the so-called soft-gluon-pole (SGP) in the twist-3 collinear factorization approach. However, there are also contributions from so-called soft-fermon-pole (SFP) [30]. Even though our modified GPM formalism might capture the main feature of SGP contributions, it seems unlikely to reproduce the SFP contributions. In this respect the twist-3 formalism is “internally complete” in the sense that the collinear factorization is expected to hold for this formalism [31]. Finally, while TMD factorization is assumed in both GPM and our modified GPM formalisms, it is likely not to hold in these processes [28]. However, the extent to which it is broken is not known numerically. Thus, calculations within (modified) GPM formalisms should bear this in mind and thus be used with extra care.

### III. NUMERICAL ESTIMATE OF THE SSAS

In this section, we will estimate the SSAs for single inclusive hadron and direct photon production in \(pp\) collisions at RHIC energy by using our modified GPM formalism in Eq. (20). We will compare our results with those calculated from the conventional GPM formalism as in Eq. (1).

To calculate the spin-averaged cross section, we use GRV98 LO parton distribution functions [32] along with a Gaussian-type \(k_T\)-dependence [21, 22]. The hard part functions for different partonic scattering channels are available in the literature [15, 32, 34]. For the spin-dependent cross section, we use the latest Sivers functions from [22] which are extracted from the recent SIDIS experiments. To consistently use this set of Sivers function, we will use DSS fragmentation function [35]. For the numerical predictions below, we work in a frame in which the polarized hadron moves in the +z-direction, choosing \(S_z, P_{h\perp}\) along y- and z-directions, respectively, where all the relevant distribution functions and fragmentation functions are evaluated at the scale \(P_{h\perp}\) [17].

In Fig. 5 we plot the \(A_N\) as a function of \(x_F\) for inclusive \(\pi^0\) (left) and direct photon (right) production at rapidity \(y = 3.3\) for RHIC energy \(\sqrt{s} = 200\) GeV. The estimates using the conventional GPM formalism in Eq. (1) are shown as dashed lines, while those using our modified GPM formalism in Eq. (20) are shown as solid lines. One immediately see that for both inclusive \(\pi^0\) and direct photon, \(A_N\) change signs compared to the conventional GPM formalism. For
the conventional GPM predicts a negative asymmetry (though very small from this set of Sivers functions), while the modified GPM formalism predicts a positive asymmetry. On the other hand, for direct photon, conventional GPM formalism predicts a positive asymmetry, while modified GPM formalism predicts that the asymmetry is negative, which is consistent with the predictions from twist-3 collinear factorization approach \cite{15}. This can also be easily understood as follows. In the conventional GPM approach, one use $H_U$ in the calculation of the spin-dependent cross section. For direct photon production, the dominant channel comes from $qg \rightarrow \gamma q$, with \cite{15, 33}:

$$H_{qg \rightarrow \gamma q}^U = \frac{1}{N_c^2} \left[ -\frac{\hat{t}}{s} - \frac{\hat{s}}{t} \right] \tag{48}$$

while the hard part in the modified GPM formalism is given by

$$H_{qg \rightarrow \gamma q}^{\text{Inc}} = -\frac{N_c}{N_c^2 - 1} \frac{\hat{t}}{s} \left[ -\frac{\hat{t}}{s} - \frac{\hat{s}}{t} \right]. \tag{49}$$

This introduces an extra color factor $-N_c^2/(N_c^2 - 1)$, thus opposite to the conventional GPM formalism. This prediction comes from the process-dependence of the Sivers functions, and has the same origin as in the photon+jet calculation \cite{30}. On the other hand, for the inclusive $\pi^0$ production, the dominant channel comes from $\gamma g \rightarrow qg$, particularly in the forward direction, one has

$$H_{\gamma g \rightarrow qg}^{\text{Inc}} = H_{\gamma g \rightarrow qg}^{\text{Inc}-1} + H_{\gamma g \rightarrow qg}^{\text{Inc}-F} \rightarrow -\frac{N_c^2}{2(N_c^2 - 1)} \frac{2\hat{s}^2}{t^2} \frac{1}{N_c^2 - 1} \frac{2\hat{t}^2}{t^2} = -\frac{N_c^2 + 2\hat{s}^2}{N_c^2 - 1} \frac{2\hat{t}^2}{t^2}, \tag{50}$$

where we have used that in the forward direction, $\hat{t}$ is small, while $\hat{u} \sim -\hat{s}$, whereas \cite{15, 33}:

$$H_{\gamma g \rightarrow qg}^U = -\frac{N_c^2 - 1}{2N_c^2} \left[ -\frac{\hat{s}}{u} - \frac{\hat{u}}{s} \right] + \frac{\hat{s}^2 + \hat{u}^2}{t^2} \rightarrow \frac{2\hat{s}^2}{t^2}. \tag{51}$$

We thus also see the sign is reversed in our modified GPM formalism compared with the conventional GPM approach.

We observe that the $x_F$-dependence in both modified and conventional GPM formalisms are different from those observed in the RHIC experiments where larger asymmetries have been observed in the forward direction (large $x_F$) \cite{14}. Of course, in order to have a comparison with the experimental data for inclusive hadron production at RHIC experiments, one must include both Sivers (as studied in this paper) and Collins effects \cite{37}. The latter describes a transversely polarized quark jet fragmenting into an unpolarized hadron, whose transverse momentum relative to the jet axis correlates with the transverse polarization vector of the fragmenting quark. This latter correlation can also generate the transverse spin asymmetry (which is not studied here). Currently attempts at global fitting with both SIDIS and $pp$ experimental data are ongoing \cite{10}. We encourage the use of the modified GPM formalism in such a global analysis, to study the effect of the associated ISIs and FSIs (process-dependence of the Sivers functions). We also emphasize \cite{36} that there is only Sivers contribution in direct photon production. Since the modified and conventional GPM predict opposite asymmetries, direct photon production presents a favorable opportunity to test the process dependence of the Sivers function, or the effect of the associated ISIs.
IV. SUMMARY

In this paper, we have studied the single transverse spin asymmetries in the single inclusive particle production in hadronic collisions. We point out the Sivers functions in such processes are generally different from those probed in the SIDIS process because of different initial- and final-state interactions. By carefully taking into account the process-dependence in the Sivers functions (under one-gluon exchange approximation), we derive a new formalism within the framework of GPM approach. We find this formalism has close connections with the collinear twist-3 approach. With our modified GPM formalism, we make predictions for the inclusive $\pi^0$ and direct photon production in $pp$ collisions at RHIC energies. We find that the asymmetries predicted from the modified GPM formalism are opposite to those in the conventional GPM approach. This sign difference comes from the color gauge interaction, which has the same origin as the sign change for Sivers functions between SIDIS and DY processes. Our predictions about the sign are consistent with those from the twist-3 collinear factorization approach. We encourage a global analysis of both SIDIS and $pp$ experimental data using this modified GPM formalism.
