LACK OF REGULARITY OF THE TRANSPORT DENSITY
IN THE MONGE PROBLEM

SAMER DWEIK

Abstract. In this paper, we provide a family of counter-examples to the regularity of the transport density in the classical Monge-Kantorovich problem. We prove that the $W^{1,p}$ regularity of the source and target measures $f^\pm$ does not imply that the transport density $\sigma$ is $W^{1,p}$, that the BV regularity of $f^\pm$ does not imply that $\sigma$ is BV and that $f^\pm \in C^\infty$ does not imply that $\sigma$ is $W^{1,p}$, for large $p$.

1. Introduction

The mass transport problem dates back to a work from 1781 by Gaspard Monge, Mémoire sur la théorie des déblais et des remblais ([16]), where he formulated a natural question in economics which deals with the optimal way of moving points from one mass distribution to another so that the total work done is minimized. In his work, the cost of moving one unit of mass from $x$ to $y$ is measured with the Euclidean distance $|x - y|$, even though many other cost functions have been studied later on.

In order to explain this problem in full details, let us consider $f^\pm$ two given finite positive Borel measures in $\Omega$ satisfying the mass balance condition $f^+(\Omega) = f^-(\Omega)$, where $\Omega$ is a compact convex set in $\mathbb{R}^d$. Let $|.|$ stand for the Euclidean norm in $\mathbb{R}^d$. Then, the classical Monge optimal transportation problem ([16]) consists in finding a transport map $T : \Omega \mapsto \Omega$ minimizing the functional

$$T \mapsto \int_{\Omega} |x - T(x)| \, df^+,$$

among all Borel measurable maps $T : \Omega \mapsto \Omega$ which satisfy the “push-forward” condition $T#f^+ = f^-$, i.e.

$$f^-(A) = f^+(T^{-1}(A))$$

for every Borel set $A \subset \Omega$.

The existence of optimal maps was addressed by many authors [1], [4], [10], [17] and [20] (see [5] for the most general result, which is valid for arbitrary norms $|x - y|$; however in this paper we will concentrate only on the Euclidean case). Although this problem may have no solutions, its relaxed setting (which is the Kantorovich problem [15]) always has one. The relaxed problem consists in finding a Borel measure $\lambda$ over $\Omega \times \Omega$ (called optimal transport plan) satisfying $\pi^+_\# \lambda = f^\pm$, where $\pi^\pm : \Omega \times \Omega \mapsto \Omega$ being the projections on the first and second factor, respectively (i.e. $\pi^\pm(x^+,x^-) := x^\pm$), which minimizes the functional

$$\lambda \mapsto \int_{\Omega \times \Omega} |x - y| \, d\lambda$$

among all Borel measures $\lambda$ on $\Omega \times \Omega$ satisfying $\pi^+_\# \lambda = f^\pm$. For the details about Optimal Transport theory, its history, and the main results, we refer to [19] and [21]. It is also possible to prove that the maximization of the functional

$$u \mapsto \int_{\Omega} u \, d(f^+ - f^-),$$

among all the 1-Lipschitz functions $u$ on $\Omega$, is the dual to the Kantorovich problem (a maximizer for this problem is called Kantorovich potential). This duality implies that optimal $\lambda$ and $u$ satisfy
The amount of transport taking place in each region of $\Omega$. This measure $\sigma$ is defined by

\begin{equation}
< \sigma, \varphi > := \int_{\Omega} d\lambda(x,y) \int_0^1 \varphi((1-t)x + ty)|x-y|\,dt \quad \text{for all } \varphi \in C(\Omega).
\end{equation}

It is well known that $(\sigma, u)$ solves a particular PDE system, called Monge-Kantorovich system:

\begin{equation}
\begin{cases}
-\nabla \cdot (\sigma \nabla u) = f^+ - f^- & \text{in } \Omega \\
\sigma \nabla u \cdot n = 0 & \text{on } \partial \Omega, \\
|\nabla u| \leq 1 & \text{in } \Omega, \\
|\nabla u| = 1 & \sigma - \text{a.e.}
\end{cases}
\end{equation}

The $L^p$ regularity of the transport density $\sigma$ is proved successively by many authors (see, for instance, [7, 8, 9, 11, 18]). In particular, we have the following

**Proposition 1.1.** Suppose $f^+ \ll \mathcal{L}^d$ or $f^- \ll \mathcal{L}^d$. Then, the transport density $\sigma$ is unique (i.e does not depend on the choice of the optimal transport plan $\lambda$) and $\sigma \ll \mathcal{L}^d$. Moreover, if both $f^+, f^- \in L^p(\Omega)$, then $\sigma$ also belongs to $L^p(\Omega)$.

The higher order regularity of the transport density $\sigma$ is still widely open; the only known results are in $\mathbb{R}^2$: if $f^\pm$ are two positive densities, continuous and have compact, disjoint, convex support, then the “monotone optimal transport map” $T$ is continuous except on a negligible set (the endpoints of transport rays) and the transport density $\sigma$ is actually continuous everywhere ([12]). Moreover, in [13], the authors prove the continuity of the same map $T$ under the assumptions that $f^\pm$ are two positive densities, continuous with $\text{spt}(f^+) \subset \text{spt}(f^-)$ and one of the sets $\{f^+ > f^-, f^- > f^+\}$ is convex (it will be that the transport density $\sigma$ is also continuous in this case). Other results exist as far as the regularity in some directions is concerned: in [10], it has been proven that when $f^\pm$ are Lipschitz continuous with disjoint supports (and with some extra technical condition on the supports), then the transport density is locally Lipschitz continuous “along transport rays”. Also in [3], the authors have a more general result for the case of just summable $f^\pm$ without any extra conditions on supports; they prove that if $f^\pm \in L^p(\Omega)$, then for a.e $x \in \Omega$, the transport density $\sigma \in W^{1,p}(R_x)$, where $R_x$ is the transport ray passing through $x$. As one can see, the $W^{1,p}(\Omega) (C^{0,\alpha}(\Omega), BV(\Omega), ...)$ regularity of the transport density $\sigma$ is an interesting question, and the aim of this paper is to give a (negative) answer to it!

In this paper we focus on examples relating the regularity of the initial data $f^\pm$ with the regularity of the transport density $\sigma$. As a starting point, the following example shows that in general, the transport density $\sigma$ is not more regular than the initial data: consider $\chi^+ := [0,1]^2$, $\chi^- := [2,3] \times [0,1]$ and set $f^+(x_1, x_2) := f_1(x_1)f_2(x_2)$, where we suppose that $f^+$ is concentrated on $\chi^+$, and take $f^-(x_1, x_2) := f^+(x_1 - 2, x_2)$, for every $(x_1, x_2) \in \chi^-$. In this case, it is easy to compute the transport density $\sigma$ between $f^\pm$, so we get $\sigma(x_1, x_2) = (\int_{x_1}^{x_1+1} f_1(t)\,dt)f_2(x_2)$ for every $x \in \chi^+$. Hence, the transport density $\sigma$ has the same regularity as $f^\pm$ in the $x_2$-variable. Yet, we will give examples where the regularity of the transport density $\sigma$ is worse than the regularity of the initial data $f^\pm$. In particular, we will prove among others the following statements:

\begin{align}
(1.3) & \quad f^\pm \in W^{1,p}(\Omega) \not\Rightarrow \sigma \in W^{1,p}(\Omega), \quad \forall \ p > 1, \\
(1.4) & \quad f^\pm \in BV(\Omega) \not\Rightarrow \sigma \in BV(\Omega), \\
(1.5) & \quad f^\pm \in C^\infty(\Omega) \not\Rightarrow \sigma \in W^{1,3}(\Omega).
\end{align}
2. Main Results

Inspired by [6, 14], we will construct a family of counter-examples by, first, choosing which lines will be transport rays. Set $\gamma > 0$ and consider the following transport rays:

\begin{equation}
 l_a := \left\{(x_1, x_2) \in \mathbb{R}^2 : x_2 = \frac{a\gamma}{2} (x_1 + a), x_1 \in (-a, 1)\right\}, \quad a \in [0, 1].
\end{equation}

It is clear that the segments $l_a$ do not mutually intersect. The domain representing both source and target will be $\Delta \subset \mathbb{R}^2$ (see Figure 1), where

\begin{equation}
\Delta := \text{interior of the triangle with vertices } (-1, 0), (1, 0) \text{ and } (1, 1).
\end{equation}

The initial and final density will have the form

\begin{equation}
 f^+(x_1, x_2) = 1, \quad f^-(x_1, x_2) = 1 + \beta(\zeta''(x_1) + \eta''(x_2)) \quad \text{for all } x := (x_1, x_2) \in \Delta,
\end{equation}

where $\zeta(x_1) := -x_1^2(x_1 - 1)^2$ (the choice of $\zeta$ is made essentially in such a way that $\zeta(1) = \zeta'(1) = 0$), $\eta$ is a $C^2$ function with $\eta(0) = \eta'(0) = 0$ and $\beta > 0$ is chosen so that $f^-$ will be a non-negative density. Note that $\eta$ is constructed in such a way that the following mass balance condition for the region in the domain below each $l_a$ is satisfied:

\begin{equation}
\int_{\Delta_a} f^+ = \int_{\Delta_a} f^- \quad \text{for all } a \in [0, 1],
\end{equation}

where $\Delta_a$ is the subgraph of $l_a$ in $\Delta$, namely the triangle formed by $(-a, 0), (1, 0)$ and $(1, \frac{a\gamma}{2}(1 + a))$; or equivalently, (2.4) can be rewritten as

\begin{equation}
-\int_{\Delta_a} \zeta''(x_1) \, dx_1 \, dx_2 = \int_{\Delta_a} \eta''(x_2) \, dx_1 \, dx_2 \quad \text{for all } a \in [0, 1].
\end{equation}

Yet, it is easy to see that

\begin{align*}
-\int_{\Delta_a} \zeta''(x_1) \, dx_1 \, dx_2 &= -\int_0^{\frac{a\gamma}{2}(1+a)} \int_{\frac{a\gamma}{2}x_2 - a}^1 \zeta''(x_1) \, dx_1 \, dx_2 \\
&= \int_0^{\frac{a\gamma}{2}(1+a)} \zeta'\left(\frac{2}{a\gamma}x_2 - a\right) \, dx_2 \\
&= \frac{a\gamma^2}{2}(1 + a)^2
\end{align*}
and as \( \eta(0) = \eta'(0) = 0 \), we have
\[
\int_{\Delta_a} \eta''(x_2) \, dx_1 \, dx_2 = \int_{-a}^{1} \int_{0}^{x_1+a} \eta''(x_2) \, dx_2 \, dx_1
\]
\[
= \int_{-a}^{1} \eta'(\frac{a^\gamma}{2}(x_1 + a)) \, dx_1
\]
\[
= \frac{\eta(\frac{a^\gamma}{2}(1 + a))}{a^\gamma}.
\]
Then,
\[
\eta(s) = s^2 a^2(s), \quad \forall \ s \in (0, 1)
\]
where \( a(s) \) is the unique solution of
\[
(2.5) \quad s = \frac{a^\gamma}{2}(1 + a).
\]
Yet, by the implicit function theorem, it is easy to see that there exists a \( C^\infty \) function \( h \) defined in a neighborhood of \( 0 \) such that
\[
s = \frac{h(s)}{2^\frac{s}{\gamma}}(1 + h(s))^\frac{s}{\gamma}.
\]
Hence, \( h(s^\frac{s}{\gamma}) \) is a solution to \((2.5)\) and \( \eta(s) = s^2 h^2(s^\frac{s}{\gamma}) \). After tedious computations, we can check that
\[
\eta'(s) = 2 s h^2(s^\frac{s}{\gamma}) + \frac{2}{\gamma} s^\frac{s}{\gamma} + h(s^\frac{s}{\gamma}) h'(s^\frac{s}{\gamma}),
\]
\[
\eta''(s) = 2 h^2(s^\frac{s}{\gamma}) + \left( \frac{6}{\gamma} + \frac{2}{\gamma^2} \right) s^\frac{s}{\gamma} h(s^\frac{s}{\gamma}) h'(s^\frac{s}{\gamma}) + \frac{2}{\gamma} s^\frac{s}{\gamma} (h'(s^\frac{s}{\gamma}))^2 + h(s^\frac{s}{\gamma}) h''(s^\frac{s}{\gamma}),
\]
\[
\eta'''(s) = \left( \frac{4}{\gamma} + \frac{6}{\gamma^2} + \frac{2}{\gamma^3} \right) s^{\frac{s}{\gamma} - 1} h(s^\frac{s}{\gamma}) h'(s^\frac{s}{\gamma}) + \left( \frac{6}{\gamma^3} + \frac{6}{\gamma^2} \right) s^{\frac{s}{\gamma} - 1} (h'(s^\frac{s}{\gamma}))^2 + h(s^\frac{s}{\gamma}) h''(s^\frac{s}{\gamma})
\]
\[
+ \frac{6}{\gamma^3} s^{\frac{s}{\gamma} - 1} h'(s^\frac{s}{\gamma}) h''(s^\frac{s}{\gamma}) + \frac{2}{\gamma^3} s^{\frac{s}{\gamma} - 1} h(s^\frac{s}{\gamma}) h'''(s^\frac{s}{\gamma}),
\]
and
\[
\eta''''(s) = \left( \frac{14}{\gamma^4} + \frac{12}{\gamma^3} \right) s^{\frac{s}{\gamma} - 2} (h'(s^\frac{s}{\gamma}))^2 + \left( \frac{2}{\gamma^4} + \frac{4}{\gamma^3} - \frac{2}{\gamma^2} \right) s^{\frac{s}{\gamma} - 2} h(s^\frac{s}{\gamma}) h'(s^\frac{s}{\gamma}) + \frac{4}{\gamma^2} s^{\frac{s}{\gamma} - 2} h(s^\frac{s}{\gamma}) h''(s^\frac{s}{\gamma})
\]
\[
+ \left( \frac{14}{\gamma^3} + \frac{12}{\gamma^2} - \frac{2}{\gamma} \right) s^{\frac{s}{\gamma} - 2} h(s^\frac{s}{\gamma}) h''(s^\frac{s}{\gamma}) + \left( \frac{30}{\gamma^4} + \frac{12}{\gamma^3} \right) s^{\frac{s}{\gamma} - 2} h'(s^\frac{s}{\gamma}) h''(s^\frac{s}{\gamma}) + \frac{8}{\gamma^3} s^{\frac{s}{\gamma} - 2} h'(s^\frac{s}{\gamma}) h'''(s^\frac{s}{\gamma})
\]
\[
+ \left( \frac{12}{\gamma^4} + \frac{4}{\gamma^3} \right) s^{\frac{s}{\gamma} - 2} h(s^\frac{s}{\gamma}) h'''(s^\frac{s}{\gamma}) + \frac{2}{\gamma^4} s^{\frac{s}{\gamma} - 2} h(s^\frac{s}{\gamma}) h''''(s^\frac{s}{\gamma}).
\]
Hence,
\[
\begin{cases}
\eta(\cdot, \cdot) \in C^\infty(\mathbb{R}) & \text{if } \gamma = \frac{1}{2}, \\
\eta \in C^\infty[0, +\infty) \text{ and } \eta(\cdot, \cdot) \in C^{4,1}(\mathbb{R}) & \text{if } \gamma = 1, \\
\eta(\cdot, \cdot) \in C^{3, \frac{1}{2} - 1}(\mathbb{R}) & \text{if } 1 < \gamma < 2, \\
\eta \in C^{3}[0, +\infty) \text{ and } \eta(\cdot, \cdot) \in C^{2,1}(\mathbb{R}) & \text{if } \gamma = 2, \\
\eta(\cdot, \cdot) \in C^{2, \frac{1}{2} - \varepsilon}(\mathbb{R}) \cap W^{3, \frac{1}{2} - \varepsilon}(\mathbb{R}) & \text{if } \gamma > 2, \varepsilon > 0.
\end{cases}
\]
Let \( T \) be an optimal transport map between \( \sigma \) and \( \eta \), and let \( W \equiv \Delta \). To obtain counter-examples to interior regularity of the transport density, it suffices to reflect the domain across the \( x_1 \)-axis on \( \Delta \). Extension of the functions \( f^\pm \) to \( \Omega \) so that they are symmetric with respect to the \( x_1 \)-axis. Let \( T \) be an optimal transport map between \( f^\pm \) and let \( \sigma \) be the transport density between them, then it is easy to prove the map \( S \), which is equal to \( T \) on \( \Delta \) and to the reflection of \( T \) with respect to the \( x_1 \)-axis on \( \Delta \), is an optimal transport map between the extended densities and the transport density between them is equal to \( \sigma \) on \( \Delta \) and to the reflection of \( \sigma \), with respect to the \( x_1 \)-axis, on \( \Delta \).

Using this fact and (2.6), we get the following statements:

- \( f^\pm \in W^{1,p}(\Omega) \not\Rightarrow \sigma \in W^{1,\frac{2p}{p+1}}(\Omega), \forall \varepsilon > 0, p > 1, \) (2.15)
- \( f^\pm \in C^{0,\alpha}(\Omega) \not\Rightarrow \sigma \in C_{loc}^{0,\frac{\alpha}{p+1}+\varepsilon}(\Omega), \forall \varepsilon > 0, \alpha \in (0,1), \) (2.16)
- \( f^\pm \in C^{0,1}(\Omega) \not\Rightarrow \sigma \in H^1(\Omega) \cup C_{loc}^{0,\frac{1}{p+1}+\varepsilon}(\Omega), \forall \varepsilon > 0, \) (2.17)
- \( f^\pm \in C^{1,\alpha}(\Omega) \not\Rightarrow \sigma \in W^{1,2+\alpha}(\Omega) \cup C_{loc}^{0,\frac{1}{p+1}+\varepsilon}(\Omega), \forall \varepsilon > 0, \alpha \in (0,1), \) (2.18)
- \( f^\pm \in C^{2,1}(\Omega) \not\Rightarrow \sigma \in W^{1,3}(\Omega) \cup C_{loc}^{0,\frac{1}{p+1}+\varepsilon}(\Omega), \forall \varepsilon > 0, \) (2.19)
- \( f^\pm \in C^\infty(\Omega) \not\Rightarrow \sigma \in W^{1,5}(\Omega) \cup C_{loc}^{0,\frac{1}{p+1}+\varepsilon}(\Omega), \forall \varepsilon > 0. \) (2.20)
3. Proof

In this section, we want to prove Propositions 2.1 & 2.3. Firstly, we will compute the transport density $\sigma$ between $f^+$ and $f^-$. To do that, let us observe that the family $\{l_a, a \in (0, 1)\}$, where $l_a$ is defined as in (2.1), covers $\Delta$ so that for every $x := (x_1, x_2) \in \Delta$, there exists a unique pair $(t, a) \in (0, 1)^2$ such that $x \in l_a$ and $|x - (-a, 0)| = tl(a)$, where $l(a)$ is the length of $l_a$. In other words, we have

$$x = (-a + (1 + a)t, (1 + a)\frac{ta\gamma}{2}).$$

Fix $(t, a) \in (0, 1)^2$ and set,

$$\omega_\varepsilon := \left\{ \left( -s + (1 + s)t, (1 + s)\frac{ts\gamma}{2} \right), (\tau, s) \in [0, t] \times [a, a + \varepsilon] \right\}$$

where $\varepsilon > 0$ is small enough. Recalling (1.2) and integrating $-\nabla \cdot (\sigma\nabla u) = f$ on $\omega_\varepsilon$, we get

(3.1) $$-\int_{\partial\omega_\varepsilon} \sigma \nabla u \cdot n = \int_{\omega_\varepsilon} f.$$  

Suppose that the family of segments $(l_a)_{a \in (0, 1)}$ are, in fact, all the transport rays on which the optimal transport map, between $f^+$ and $f^-$, acts. In this case, we get that for every $x \in l_a$:

$$\nabla u(x) = \frac{(-a, 0) - (1, (1 + a)\frac{a\gamma}{2})}{||(-a, 0) - (1, (1 + a)\frac{a\gamma}{2})||} = \frac{-(1, \frac{a\gamma}{2})}{\sqrt{1 + (\frac{a\gamma}{2})^2}}$$

which means that $\nabla u(x) \cdot n = 0$ if $n$ is the unit orthogonal vector to $l_a$. Hence, (3.1) becomes

(3.2) $$-\int_{s_\varepsilon} \sigma \nabla u \cdot n = \int_{\omega_\varepsilon} f$$

where $s_\varepsilon := \left\{ (-s + (1 + s)t, (1 + s)\frac{ts\gamma}{2}), s \in [a, a + \varepsilon] \right\}$. Yet, we have
\[
\int_{\omega} f(x_1, x_2) \, dx_1 \, dx_2 = \int_{\omega} -\beta(\zeta''(x_1) + \eta''(x_2)) \, dx_1 \, dx_2
\]

\[
= \int_{a}^{a+\varepsilon} \int_{0}^{t} -\beta \left( \zeta''(-s + (1 + s)\tau) + \eta'' \left( (1 + s)\frac{\tau s^\gamma}{2} \right) \right) J(\tau, s) \, d\tau \, ds,
\]

where \( J := |\det(D_{(\tau,s)}(x_1, x_2))| \). Yet,

\[
D_{(t,a)}(x_1, x_2) := \begin{pmatrix}
\frac{\partial x_1}{\partial t} & \frac{\partial x_1}{\partial a} \\
\frac{\partial x_2}{\partial t} & \frac{\partial x_2}{\partial a}
\end{pmatrix} = \begin{pmatrix}
1 + a & -1 + t \\
(1 + a)\gamma & (\gamma (1 + a) + a)\frac{a^{-\gamma - 1}}{2}
\end{pmatrix}.
\]

Then,

\[
(3.3) \quad J(t, a) = (1 + a)(\gamma (1 + a) t + a)\frac{a^{-\gamma - 1}}{2}.
\]

On the other hand,

\[
-\nabla u \cdot n = \frac{\partial_t x}{|\partial_t x|} \cdot R \frac{\partial_a x}{l(a)} = \frac{J(t, a)}{l(a)}
\]

where \( R := \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \) is the rotation matrix. Hence,

\[
-\int_{s_*}^{a+\varepsilon} \sigma \nabla u \cdot n = \int_{a}^{s_*} \sigma \left( -s + (1 + s)\tau, (1 + s)\frac{ts^\gamma}{2} \right) J(t, s) \frac{l(t)}{l(s)} \, ds.
\]

By (3.2), we infer that

\[
\lim_{\varepsilon \to 0^+} \frac{1}{\varepsilon} \int_{a}^{a+\varepsilon} \sigma \left( -s + (1 + s)\tau, (1 + s)\frac{ts^\gamma}{2} \right) J(t, s) \frac{l(t)}{l(s)} \, ds
\]

\[
= \lim_{\varepsilon \to 0^+} \frac{1}{\varepsilon} \int_{a}^{a+\varepsilon} \int_{0}^{t} -\beta \left( \zeta''(-s + (1 + s)\tau) + \eta'' \left( (1 + s)\frac{\tau s^\gamma}{2} \right) \right) J(\tau, s) \, d\tau \, ds.
\]

Finally, we get

\[
(3.4) \quad \sigma(x) = \frac{l(a) \int_{0}^{t} -\beta(\zeta''(-a + (1 + a)\tau) + \eta''((1 + a)\frac{a^{-\gamma - 1}}{2})) J(\tau, a) \, d\tau}{J(t, a)}.
\]

Now, we are ready to prove Proposition 2.3. Indeed, for every \( \varepsilon > 0 \), let \( (t_\varepsilon, a_\varepsilon) \) be in \( (0, 1)^2 \) such that

\[
x_\varepsilon := (0, \varepsilon) = \left( -a_\varepsilon + (1 + a_\varepsilon)t_\varepsilon, (1 + a_\varepsilon)\frac{t_\varepsilon a_\varepsilon^{-\gamma - 1}}{2} \right).
\]

As \( \zeta''(0) < 0 \) and \( \eta''(0) = 0 \), then, from (3.4), we can see easily that, close to the origin, we have

\[
\sigma \approx \frac{\int_{0}^{t} J(\tau, a) \, d\tau}{J(t, a)}
\]
where \( f \approx g \) means that there exist \( c^\pm > 0 \) such that \( c^- g \leq f \leq c^+ g \). Yet, by (3.3), one has
\[
\int_0^t J(\tau, a) \, d\tau = \frac{t}{2} \left( J(t, a) + (1 + a) \frac{a^\gamma}{2} \right).
\]

As \( t_\varepsilon = \frac{a^\varepsilon}{1 + a^\varepsilon} \) and \( \varepsilon = \frac{a^\gamma}{2} \), we infer that \( t_\varepsilon \approx \varepsilon^{\frac{1}{\gamma + 1}} \). Hence,
\[
\sigma(x_\varepsilon) \approx \varepsilon\frac{1}{\gamma + 1}.
\]

This completes the proof of the proposition 2.3. Next, to prove Proposition 2.1, we will only look at \( \partial x \sigma \) close to the origin and to do that, we want to compute, firstly, \( \partial_t \sigma \) and \( \partial_a \sigma \). Differentiating (3.4) with respect to \( t \) and \( a \) respectively, we get
\[
(3.5) \quad \partial_t \sigma(x) = l(a) f(x) - \frac{\partial_t J(t, a)}{J(t, a)} \sigma(x),
\]
and
\[
(3.6) \quad \partial_a \sigma(x) = \frac{\partial_a l(a)}{l(a)} \sigma(x) - \frac{\partial_a J(t, a)}{J(t, a)} \sigma(x) + K_1(t, a) + K_2(t, a)
\]
where,
\[
K_1(t, a) := \frac{l(a) \int_0^t - \beta(\zeta''(-a + (1 + a)\tau) + \eta''((1 + a)\frac{\tau a^\gamma}{2})) \partial_a J(\tau, a) \, d\tau}{J(t, a)}
\]
and
\[
K_2(t, a) := \frac{l(a) \int_0^t - \beta(-1 - \tau) \zeta''''(-a + (1 + a)\tau) + \frac{\tau a^\gamma - 1}{2}(\gamma(1 + a) + a) \eta''''((1 + a)\frac{\tau a^\gamma}{2})) J(\tau, a) \, d\tau}{J(t, a)}.
\]

Now, we claim that, for any \( \gamma \geq \frac{1}{2} \),
\[
(3.7) \quad \partial_a \sigma \approx t + \left( \frac{t}{t + a} \right)^2.
\]
From Section 2, we have
\[
(3.8) \quad |\eta'''(x_2)| \leq C x_2^{\frac{3}{2} - 1}, \quad \text{for all } x_2 \in (0, 1)
\]
where \( C := C(\gamma) \). Then,
\[
\left| \frac{\tau a^\gamma - 1}{2}(\gamma(1 + a) + a) \eta'''' \left( (1 + a)\frac{\tau a^\gamma}{2} \right) \right| \leq C \tau^{\frac{3}{2}} a.
\]
As \( \zeta'''(0) > 0 \), we infer that
\[
K_2(t, a) \approx t.
\]
In addition, it is easy to see that
\[
\frac{\partial_a l(a)}{l(a)} \sigma(x) = \frac{4 + a^{2\gamma} + \gamma(1 + a) a^{2\gamma - 1}}{(1 + a)(4 + a^{2\gamma})} \sigma(x) \approx t.
\]
On the other hand,

\[
K_1(t,a) \frac{\partial_a J(t,a)}{J(t,a)} \sigma(x) = \frac{l(a) \int_0^t f(-a + (1 + a)\tau, (1 + a)\frac{\tau}{2}) (J(t,a) \partial_a J(\tau,a) - J(\tau,a) \partial_a J(t,a)) d\tau}{J(t,a)^2}.
\]

Yet, by (3.3), we have

\[
\partial_a J(t,a) = (\gamma (\gamma - 1) (1 + a)^2 t + (\gamma (1 + a) (1 + 2t) + a) a^{\gamma^2} \frac{t}{2}.
\]

Then, it is not difficult to check that

\[
J(t,a) \partial_a J(\tau,a) - J(\tau,a) \partial_a J(t,a) = \frac{\gamma}{4} (1 + a)^2 (t - \tau) a^{2\gamma^2}.
\]

Using (3.3) again, we infer that

\[
K_1(t,a) - \frac{\partial_a J(t,a)}{J(t,a)} \sigma(x) \approx \left( \frac{t}{t + a} \right)^2.
\]

This completes the proof of (3.7). Now, our aim is to prove that

\[
\partial_t \sigma \approx 1.
\]

Fix \( \delta > 0 \). As \( \eta''(0) = 0 \), then, near the origin, we can assume that

\[
|f(x) - 2\beta| < \delta.
\]

From (3.5), we get

\[
\partial_t \sigma(x) \geq l(a) \left( 2\beta - \delta - \frac{\int_0^t \partial_t J(t,a) J(\tau,a) d\tau}{J(t,a)^2} (2\beta + \delta) \right).
\]

Yet,

\[
\partial_t J(t,a) = \frac{\gamma}{2} (1 + a)^2 a^{\gamma^2 - 1}
\]

and then,

\[
\frac{\int_0^t \partial_t J(t,a) J(\tau,a) d\tau}{J(t,a)^2} = \frac{1}{2} \left( 1 - \frac{a^2}{(\gamma (1 + a) t + a)^2} \right).
\]

Hence,

\[
\partial_t \sigma(x) \geq \beta - \frac{3\delta}{2} > 0.
\]

In the same way, we can prove that \( \partial_t \sigma \) is bounded from above and then, (3.9) follows. Yet,

\[
\partial_{x^2} \sigma := \partial_t \sigma \partial_{x^2} t + \partial_a \sigma \partial_{x^2} a
\]

and

\[
D_{(x_1,x_2)}(t,a) := \begin{pmatrix}
\partial_{x_1} t & \partial_{x_2} t \\
\partial_{x_1} a & \partial_{x_2} a
\end{pmatrix} = \frac{1}{J(t,a)} \begin{pmatrix}
(\gamma (1 + a) + a) \frac{a^{\gamma - 2}}{2} & 1 - t \\
-(1 + a) a^{\gamma - 2} & 1 + a
\end{pmatrix}.
\]
Hence, by (3.7) & (3.9), we get
\[ \partial_x \sigma \approx \frac{1}{J}, \]
and
\[ \|\partial_x \sigma\|^p L^p(\Delta) \approx \int_0^\delta \int_0^\delta \frac{1}{a(\gamma-1)(p-1)(t + a)^{p-1}} dt \, da \]
where \( \delta > 0 \) small enough. From (3.3), we get
\[ \|\partial_x \sigma\|^p L^p(\Delta) \approx \int_0^\delta \int_0^\delta \frac{1}{a(\gamma-1)(p-1)(t + a)^{p-1}} dt \, da \]
\[ \approx \int_0^\delta dr \int_0^{\frac{\pi}{r}} \frac{1}{r^{\gamma(p-1)} \sin(\theta)(\gamma-1)(p-1)(\cos(\theta) + \sin(\theta))(p-1)} d\theta \]
\[ \approx \int_0^\delta dr \int_0^{\frac{\pi}{r}} \frac{1}{\sin(\theta)(\gamma-1)(p-1)} d\theta. \]

Then, the proposition 2.1 is proved. As in [6, 14], it is not difficult to prove the existence of a Kantorovich potential \( u \) to assert that the rays \( (l_a)_{a \in (0,1)} \) are, in fact, all the transport rays between \( f^+ \) and \( f^- \). This follows immediately from the fact that the unit vector of any transport ray \( l_a \) is an irrotational vector field, which implies that there is a 1-Lipschitz function \( u \) such that
\[ u(x) - u(y) = |x - y| \quad \forall \, x, y \in l_a. \]
In addition, by [4, 20], one can show that there is a unique measure preserving map \( T \) from \( (f^+, \Delta) \) to \( (f^-, \Delta) \) such that \( x \) and \( T(x) \) lie in a common \( l_a \), for all \( x \in \Delta \). Now, it is classical to infer that \( T \) is an optimal transport map between \( f^\pm \) and \( u \) is the corresponding Kantorovich potential.

4. BV counter-example

In this section, we will prove the statement (1.4). This means that we want to construct two densities \( f^\pm \in BV(\Omega) \) such that the transport density \( \sigma \) between them is not in \( BV(\Omega) \). First of all, we can see easily that for any \( \gamma > 0 \), the densities \( f^\pm \), which are constructed in Section 2, are in \( BV(\Omega) \), but it will be also the same for the transport density \( \sigma \) between them. Indeed, to get a counter-example to the \( W^{1,p} \) regularity of the transport density, for \( p \to 1 \), we need a \( \gamma \to \infty \). Hence, to get a \( BV \) counter-example, we could collect an infinity of triangles (constructed as in Section 2) with a sequence of exponents \( \gamma_n \to \infty \) (where \( \gamma_n \) is the exponent of the slopes of the transport rays in the \( n \)-th triangle, see 2.1). Actually, if we play on other parameters, we just need to take \( \gamma_n = \gamma > 1 \). To do that, let us define \( \Delta_n \) as follows:
\[ \Delta_n := \text{triangle with vertices } (-l_n, 0), \left( 1, -\frac{l_n^2}{2}(1 + l_n) \right) \text{ and } \left( 1, \frac{l_n^2}{2}(1 + l_n) \right) \]
where \( l_n := \frac{1}{n} \). Set, \( \Delta'_1 := \Delta_1 \) and, for all \( n \geq 2 \), define \( \Delta'_n \) as a suitable roto-translation of \( \Delta_n \):
\[ \Delta'_n := \{(x_1, x_2) \in \mathbb{R}^2 : (\cos(\theta_n)(x_1 + l_1) + \sin(\theta_n)x_2 - l_n, -\sin(\theta_n)(x_1 + l_1) + \cos(\theta_n)x_2) \in \Delta_n\}, \]
where
\[ \theta_n := \sum_{k=1}^{n-1} \alpha_k + \alpha_{k+1} \]
and
\[ \sin(\alpha_k) := \frac{l_k}{\sqrt{1 + \left(\frac{l_k}{2}\right)^2}}, \quad \alpha_k \in \left(0, \frac{\pi}{2}\right). \]

Finally, set
\[ \Omega := \bigcup_{n=1}^{\infty} \Delta'_n. \]

Fix \( n \in \mathbb{N}^* \). Then, after a suitable roto-translation of axis, we can assume that \( \Delta'_n = \Delta_n \). Set,
\[ f^+(x_1, x_2) := 1 \]
and
\[ f^-(x_1, x_2) := f^-_n(x_1, x_2) := 1 + \beta(\zeta''(x_1) + \eta''(|x_2|)), \quad \text{for all } (x_1, x_2) \in \Delta'_n \]
where \( \zeta \) and \( \eta \) are the same functions which are constructed in the section 2. Let us denote by \( \sigma \) the transport density between \( f^+ \) and \( f^- \). Then, the restriction of \( \sigma \) to \( \Delta'_n \) is the transport density \( \sigma_n \) between \( f^+_n := 1_{\Delta_n} \) and \( f^-_n \). Indeed, for all \( n \in \mathbb{N}^* \), if \( T_n \) is an optimal transport map between \( f^+_n \) and if \( u_n \) is the corresponding Kantorovich potential such that \( u_n(-1, 0) = 0 \), for all \( n \in \mathbb{N}^* \), then it is not difficult to check that
\[ T(x) := T_n(x), \quad \text{for a.e } x \in \Delta'_n \]
is an optimal transport map between \( f^\pm \) and the corresponding Kantorovich potential will be
\[ u(x) := u_n(x), \text{ for all } x \in \Delta'_n. \]

By (1.1), we infer that the restriction of \( \sigma \) to \( \Delta'_n \) is \( \sigma_n \). Yet, by Section 3, we have already shown that

\[ |\nabla \sigma_n| \approx \frac{1}{J_n} \]

where \( J_n \) is defined as in (3.3) on \( \Delta_n \). Hence,

\[
\sum_{n=1}^{\infty} ||\nabla \sigma_n||_{L^1(\Delta'_n)} \approx \sum_{n=1}^{\infty} \int_0^l_n \int_0^\delta |\nabla \sigma_n(t,a)| J_n(t,a) \, dt \, da \\
\approx \sum_{n=1}^{\infty} l_n \sum_{n=1}^{\infty} \frac{1}{n} = +\infty
\]

where \( \delta > 0 \) small enough. Hence, the transport density \( \sigma \notin BV(\Omega) \). On the other hand, we will show that the target mass \( f^- \) is in \( BV(\mathbb{R}^2) \). Using (3.8), it is easy to prove that

\[
\sum_{n=1}^{\infty} ||\nabla f^-_n||_{L^1(\Delta'_n)} \leq C \sum_{n=1}^{\infty} (l_n^1 + l_n^2) < +\infty.
\]

In addition, for a fixed \( n \in \mathbb{N}^* \) and after a suitable roto-translation of axis so that \( \Delta'_n = \Delta_n \), we can assume that

\[ f^-_n(x_1, x_2) = 1 + \beta(\zeta''(x_1) + \eta''(|x_2|)) \]

and

\[ f^-_{n+1}(x_1, x_2) = 1 + \beta(\zeta''(\cos(\theta_{n+1})(x_1 + l_n) + \sin(\theta_{n+1})x_2 - l_{n+1}) + \eta''(|-\sin(\theta_{n+1})(x_1 + l_n) + \cos(\theta_{n+1})x_2|)) \]

where

\[ \theta_{n+1} := \alpha_n + \alpha_{n+1} \approx l_{n+1}^\gamma. \]

Hence, it is not difficult to check that

\[
\left| f^-_{n+1} \left( x_1, \frac{l_n^2}{2}(x_1 + l_n) \right) - f^-_n \left( x_1, \frac{l_n^2}{2}(x_1 + l_n) \right) \right| \leq C(l_n^1 + l_n^2).
\]

Finally, we get

\[
\sum_{n=1}^{\infty} \int_{\partial \Delta_n \cap \partial \Delta_{n+1}} |f^-_{n+1}(z) - f^-_n(z)| \, dz \leq C \sum_{n=1}^{\infty} (l_n^1 + l_n^2) < +\infty.
\]

As \( f^- \) is bounded and \( Per(\Omega) \approx \sum_n (l_n^1 + l_n^2) < +\infty \), we infer that the target mass \( f^- \in BV(\mathbb{R}^2) \) and the statement (1.4) follows.
In this section, we want to show that is also possible to construct the target measure \( f^- \) so that it will be regular on \( \mathbb{R}^2 \). Firstly, let us observe that the function \( \zeta \) (see Section 2) can be replaced by \( \psi \zeta \), where \( \psi \) is a \( C^\infty \) function such that \( \psi = 1 \) on \([-1, 1 - \varepsilon']\) and \( \psi = 0 \) on \([1 - \varepsilon, 1]\), \((0 < \varepsilon < \varepsilon' < 1)\).

Let \( \chi_1, \chi_2 \) be two cutoff functions supported on \( \Delta \cup R(\Delta) \), where \( R \) is the reflection map with respect to the \( x_1 \)-axis, such that \( \text{spt}(\chi_2) \subset \{ \chi_1 = 1 \} \), \( \Delta_{a_0} \cap \{ x : x_1 \leq 1 - \varepsilon \} \subset \{ \chi_1 = 1 \} \) (where \( a_0 \in (\varepsilon, 1) \) is such that \( \text{spt}(\chi_2) \subset \Delta_{a_0} \cup R(\Delta_{a_0}) \), \( \Delta_{\varepsilon} \cap \{ x : x_1 \leq 1 - \varepsilon \} \subset \{ \chi_2 = 1 \} \) and \( \chi_1, \chi_2 \) are symmetric with respect to the \( x_1 \)-axis. Set,

\[
f^+ := \chi_1
\]

and

\[
f^- := \chi_1 + \beta((\psi \zeta)'(x_1) + \eta''(x_2) )\chi_2 + \varphi(x_1)c(a(x_1, |x_2|)),
\]

where \( \varphi \) is a non-negative \( C^\infty \) function such that \( \text{spt}(\varphi) \subset (1 - \varepsilon', 1 - \varepsilon) \) and \( c \) is to be determined in such a way that

\[
\int_{\Delta_{a}} f^+ = \int_{\Delta_{a}} f^- \quad \text{for all } a \in (0, 1),
\]

which is equivalent to say that

\[
- \int_{\Delta_{a}} ((\psi \zeta)'(x_1) + \eta''(x_2))\chi_2(x_1, x_2) = \int_{\Delta_{a}} \varphi(x_1)c(a(x_1, x_2)), \quad \text{for all } a \in (0, 1).
\]

Differentiating this equality with respect to \( a \), we get

\[
c(a) = - \frac{\int_{-a}^1 (\gamma(x_1 + a) + a)((\psi \zeta)'(x_1) + \eta''(\frac{a^2}{2}(x_1 + a)))\chi_2(x_1, \frac{a^2}{2}(x_1 + a)) \, dx_1}{\int_{-a}^1 (\gamma(x_1 + a) + a)\varphi(x_1) \, dx_1}, \quad \text{for all } a \in (0, 1).
\]

By (2.4), we have

\[
- \int_{-a}^1 (\gamma(x_1 + a) + a)(\psi \zeta)'(x_1) \, dx_1 = \int_{-a}^1 (\gamma(x_1 + a) + a)\eta''(\frac{a^2}{2}(x_1 + a)) \, dx_1, \quad \text{for all } a \in (0, 1).
\]

Hence, for \( a < \varepsilon \), we get

\[
c(a) = \frac{\int_{-a}^1 (\gamma(x_1 + a) + a)(\gamma(x_1 + a) + a)\eta''(\frac{a^2}{2}(x_1 + a))(1 - \chi_2(x_1, \frac{a^2}{2}(x_1 + a))) \, dx_1}{\int_{-a}^1 (\gamma(x_1 + a) + a)\varphi(x_1) \, dx_1}
\]

and

\[
c'(a) = \frac{1}{\int_{-a}^1 (\gamma(x_1 + a) + a)\varphi(x_1) \, dx_1} \left( \gamma + 1 \right) \int_{-a}^1 \eta''(\frac{a^2}{2}(x_1 + a))(1 - \chi_2(x_1, \frac{a^2}{2}(x_1 + a))) \, dx_1 + \frac{a^{\gamma - 1}}{2} \int_{-a}^1 (\gamma(x_1 + a) + a)\eta''(\frac{a^2}{2}(x_1 + a))(1 - \chi_2(x_1, \frac{a^2}{2}(x_1 + a))) \, dx_1 - (\gamma + 1) \left( \int_{-a}^1 \varphi(x_1) \, dx_1 \right) c(a)
\]

\[
- \frac{a^{\gamma - 1}}{2} \int_{-a}^1 (\gamma(x_1 + a) + a)^2 \eta''(\frac{a^2}{2}(x_1 + a)) \partial_{x_2}\chi_2(x_1, \frac{a^2}{2}(x_1 + a)) \, dx_1.
\]
By (3.8), we infer that
\[ c'(a) \leq Ca \]
and
\[ \|\nabla (\varphi c(a))\|_{L^p(\Delta)}^p \approx \int_{1-\varepsilon}^{1-\varepsilon} \left( \varphi(x_1)^p |c'(a)|^p + \|\nabla \varphi(x_1)|^p |c(a)|^p \right) \, dx_2 \, dx_1 \approx \int_0^\varepsilon \frac{1}{a^{(\gamma-(\gamma-2)p)}} \, da. \]

Hence, for $\gamma > 2$,
\[ f^- \in W^{1,\frac{2}{\gamma-2}-\varepsilon}(\mathbb{R}^2), \text{ for all } \varepsilon > 0. \]

Similarly, we get that for $\gamma = \frac{1}{2}$: $f^- \in C^\infty(\mathbb{R}^2)$, for $\gamma = 1$: $f^- \in C^{2,1}(\mathbb{R}^2)$, for $1 < \gamma < 2$: $f^- \in C^{1,\frac{1}{\gamma-1}}(\mathbb{R}^2)$ and, finally, for $\gamma = 2$: $f^- \in C^{0,1}(\mathbb{R}^2)$.
