Parabolic Conjugation and Commuting Varieties

Magdalena Boos $^1$ and Michael Bulois $^2$

Abstract

We consider the conjugation-action of an arbitrary upper-block parabolic subgroup of the general linear group on the variety of nilpotent matrices in its Lie algebra. Lie-theoretically, it is natural to wonder about the number of orbits of this action. We translate the setup to a representation-theoretic one and obtain a finiteness criterion which classifies all actions with only a finite number of orbits over an arbitrary infinite field. These results are applied to commuting varieties and nested punctual Hilbert schemes.

1 Introduction

The Lie-theoretical question whether an action of an algebraic group on an affine variety admits only finitely many orbits, is a very natural and basic one. For instance, the conjugation-action of the general linear group $\text{GL}_n$ on all square-sized nilpotent matrices is finite in this way and representatives of the orbits are given by so-called Jordan normal forms [18].

Many further actions have been examined in detail, some involving a parabolic subgroup $P$ of $\text{GL}_n$. For example, the action of $P$ on the nilradical $n_p$ of its Lie algebra $p$ [16]; or on varieties of nilpotent matrices of a certain nilpotency degree (and, in particular, on the nilpotent cone $N$ of $\text{GL}_n$) [4].

Let us assume first that $K$ is an arbitrary infinite field. In this work, we fix an upper-block parabolic subgroup $P$ of $\text{GL}_n(K)$ of block sizes $b_P := (b_1, \ldots, b_p)$ which acts on its Lie algebra $p$ and on the irreducible affine variety $N_p := p \cap N$.

The main aim of this article is to prove Theorem 5.1 and Proposition 4.3 which classifies all parabolic subgroups $P$ which act with only a finite number of orbits in $N_p$.

This gives

**Main Theorem.** *The parabolic subgroup $P$ acts finitely on $N_p$ if and only if its block size vector appears (up to symmetry) in the diagram [2.2]. The complementary cases to diagram [2.2] are displayed in diagram [2.7].*

In particular, $P$ acts infinitely if $P$ has at least 6 blocks, if $P$ has at least 3 blocks of size at least 2 or if $P$ has at least 2 blocks of size at least 6.

We also consider the same questions for the actions of a Levi subalgebra $L_P$ of $P$ on the nilpotent cone $N_p$, or on the nilradical $n_p$. Answers are given in Section [3.3].

For simplicity, most of the intermediate results of the paper are only stated with the additional assumption that $K$ is algebraically closed. Unless otherwise specified, we will assume that this is always the case.
The first step in order to prove our main theorem is to translate the Lie-theoretic setup to a setup in the representation theory of finite-dimensional algebras in Section 3. Thus, we define a quiver with relations and a certain subcategory of its representations such that the isomorphism classes in this category correspond bijectively to $P$-orbits in $N_p$. One difficulty of this correspondence is that we have to look for the number of isomorphism classes for each dimension vector.

The proof of the main theorem is approached from two directions, then. On the one hand, we use covering techniques [3, 11] in Section 4. This leads us to the study of a subcategory of representations of an acyclic quiver. Several ad-hoc infinite families of representations of this covering quiver are pointed out which allow us to find the infinite cases of our original problem in Proposition 4.3. We advance the theory of representations of our covering quiver, especially via the notion of $\Delta$-filtered representations [9]. This yields the partial results of Proposition 4.2 and 4.11.

On the other hand, we show that every remaining case is finite in Section 5. The main idea is to reduce the problem to only four cases by reduction techniques (Section 3.2). These four cases are proved by base-change-methods which make use of the representation-theoretic context and can be visualized nicely by combinatorial data.

Our results have quite interesting implications on commuting varieties and nested punctual Hilbert schemes which we discuss in Section 6. For instance, we explain how finiteness of the action of $P$ on $N_p$ is related to the dimension of the nilpotent commuting variety of $p$. We also give an example of a maximal parabolic having a reducible commuting variety.

Acknowledgments: The authors would like to thank K. Bongartz for his valuable ideas for approaching and visualizing the proof of the finite cases. M. Reineke is being thanked for helpful discussions concerning the methods of this work. The authors are grateful to Claus Michael Ringel and Gerhard Röhrle for very interesting remarks and to J. Küllshammer and U. Thiel for debating the possible use of bocs calculations.

2 Theoretical background

We include some facts about the representation theory of finite-dimensional algebras [2]. In all the definition below, $K$ can be assumed to be an arbitrary field. However, some of the results and techniques mentioned might require that $K = \overline{K}$.

Let $Q$ be a finite quiver, that is, a directed graph $Q = (Q_0, Q_1, s, t)$ of finitely many vertices $i \in Q_0$ and finitely many arrows $(\alpha : s(\alpha) \rightarrow t(\alpha)) \in Q_1$ with source map $s : Q_1 \rightarrow Q_0$ and target map $t : Q_1 \rightarrow Q_0$. A path in $Q$ is defined to be a sequence of arrows $\omega = \alpha_l \ldots \alpha_1$, such that $t(\alpha_k) = s(\alpha_{k+1})$ for all $k \in \{1, \ldots, l - 1\}$; formally we include a path $\varepsilon_i$ of length zero for each $i \in Q_0$ starting and ending in $i$. We define the path algebra $KQ$ of $Q$ to be the $K$-vector space with a basis given by the set of all paths in $Q$. The multiplication of two paths $\omega = \alpha_l \ldots \alpha_1$ and $\omega' = \beta_q \ldots \beta_1$ is defined by

$$\omega \cdot \omega' = \begin{cases} \omega \omega' & \text{if } t(\beta_q) = s(\alpha_1), \\ 0 & \text{otherwise}, \end{cases}$$

where $\omega \omega'$ is the concatenation of paths.
Let \( \text{rad}(KQ) \) be the path ideal of \( KQ \) which is the (two-sided) ideal generated by all paths of positive length. An ideal \( I \subseteq KQ \) is called admissible if there exists an integer \( s \) with \( \text{rad}(KQ)^s \subset I \subset \text{rad}(KQ)^s \).

Let us denote by \( \text{rep}(Q) \) the abelian \( K \)-linear category of finite-dimensional \( K \)-representations of \( Q \), that is, tuples
\[
((M_i)_{i \in Q_0}, (M_\alpha : M_i \to M_j)_{(i \to j) \in Q_1}),
\]
of \( K \)-vector spaces \( M_i \) and \( K \)-linear maps \( M_\alpha \). A morphism of representations \( M = ((M_i)_{i \in Q_0}, (M_\alpha)_{i \to j \in Q_1}) \) and \( M' = ((M'_i)_{i \in Q_0}, (M'_\alpha)_{i \to j \in Q_1}) \) consists of tuples of \( K \)-linear maps \( (f_i : M_i \to M'_i)_{i \in Q_0} \), such that \( f_j M_\alpha = M'_\alpha f_i \) for every arrow \( \alpha : i \to j \) in \( Q_1 \).

For a representation \( M \) and a path \( \omega \) in \( Q \) as above, we denote \( M_\omega = M_{a_1} \cdots M_{a_t} \). A representation \( M \) is called bound by \( I \) if \( \sum_{\omega} \lambda_\omega M_\omega = 0 \) whenever \( \sum_{\omega} \lambda_\omega \omega \in I \). We denote by \( \text{rep}(Q, I) \) the category of representations of \( Q \) bound by \( I \), which is equivalent to the category of finite-dimensional \( KQ/I \)-representations.

Given a representation \( M \) of \( Q \), its dimension vector \( \text{dim} M \in \mathbb{N}Q_0 \) is defined by \( (\text{dim} M_i)_{i \in Q_0} = \text{dim}_K M_i \) for \( i \in Q_0 \). For a fixed dimension vector \( d \in \mathbb{N}Q_0 \), we denote by \( \text{rep}(Q, I)(d) \) the full subcategory of \( \text{rep}(Q, I) \) of representations of dimension vector \( d \).

For certain classes of finite-dimensional algebras, a convenient tool for the classification of the indecomposable representations is the Auslander-Reiten quiver \( \Gamma(Q, I) \) of \( \text{rep}(Q, I) \). Its vertices \( [M] \) are given by the isomorphism classes of indecomposable representations of \( \text{rep}(Q, I) \); the arrows between two such vertices \( [M] \) and \( [M'] \) are parametrized by a basis of the space of irreducible maps \( f : M \to M' \). One standard technique to calculate the Auslander-Reiten quiver for certain algebras is the knitting process (see, for example, [12], IV.4). In some cases, large classes of representations or even the whole Auslander-Reiten quiver \( \Gamma(Q, I) \) can be calculated by using covering techniques: results about the connection between representations of the universal covering quiver (with relations) of \( KQ/I \) and the representations of \( KQ/I \) are available by P. Gabriel [11] and others.

A finite-dimensional \( K \)-algebra \( A := KQ/I \) is called of finite representation type, if the number of isomorphism classes of indecomposable representations is finite; otherwise it is of infinite representation type. The minimal quiver algebras of infinite representation type have been discussed by K. Bongartz; and by D. Happel and D. Vossieck, which lead to the famous Bongartz-Happel-Vossieck list (abbreviated by BHV-list), see for example [13]. If a quiver with relations contains one of the listed quivers as a subquiver, then the corresponding algebra is of infinite representation type; and the given so-called nullroots determine concrete one-parameter families of these dimension vectors.

For a fixed dimension vector \( d \in \mathbb{N}Q_0 \), we define the affine space
\[
R_d(Q) := \bigoplus_{a : i \to j} \text{Hom}_K(K^d_i, K^d_j).
\]
Its points \( m \) naturally correspond to representations \( M \in \text{rep}(Q)(d) \) with \( M_i = K^d_i \) for \( i \in Q_0 \). Via this correspondence, the set of representations bound by \( I \) corresponds to a closed subvariety \( R_d(Q, I) \subset R_d(Q) \). The group \( \text{GL}_d = \prod_{i \in Q_0} \text{GL}_{d_i} \) acts on \( R_d(Q) \)
and on $R_d(Q, I)$ via base change, furthermore the $GL_d$-orbits $O_M$ of this action are in bijection with the isomorphism classes of representations $M$ in $\text{rep}(Q, I)(d)$.

The following fact on associated fibre bundles sometimes makes it possible to translate an algebraic group action into another algebraic group action that is easier to understand (see, amongst others, [25]).

**Theorem 2.1.** Let $G$ be a linear algebraic group, let $X$ and $Y$ be $G$-varieties, and let $\pi: X \to Y$ be a $G$-equivariant morphism. Assume that $Y$ is a single $G$-orbit, $Y = G \cdot y_0$. Let $H$ be the stabilizer of $y_0$ and set $F := \pi^{-1}(y_0)$. Then $X$ is isomorphic to the associated fibre bundle $G \times^H F$, and the embedding $\phi: F \hookrightarrow X$ induces a bijection $\Phi$ between the $H$-orbits in $F$ and the $G$-orbits in $X$ preserving orbit closures and types of singularities.

Given a $G$-variety $X$, we say that $G$ acts infinitely on $X$, if the number of orbits of the action is infinite; and finitely, otherwise. We also speak about infinite or finite actions.

### 3 Actions in the quiver context

We denote by $GL_n := GL_n(K)$ the general linear group for a fixed integer $n \in \mathbb{N}$ regarded as an affine variety and by $\mathfrak{gl}_n$ its Lie algebra.

Fix an upper-block parabolic subgroup $P$ of $GL_n$ of block sizes $b_P := (b_1, \ldots, b_p)$. We denote by $L_P$ the Levi subgroup of $P$ and by $\mathfrak{p} := \text{Lie}(P)$ its Lie algebra. Given $x \leq n$, we define $N_p^{(x)}$ as the variety of $x$-nilpotent matrices in $\mathfrak{p}$. As a special case, we obtain $N_p$ for $x = n$, which is the irreducible variety of nilpotent matrices in $\mathfrak{p}$. Define $n_p$ to be the nilradical of $\mathfrak{p}$. The groups $L_P$ and $P$ act on $N_p^{(x)}$ and on $n_p$ via conjugation.

Our main aim is to answer the following question:

"For which $P$ is the number of $P$-orbits in $N_p$ finite?"

It is natural to look at a broader context and we will also consider the Levi subgroup $L_P$ as the acting group; and the nilradical $n_p$ as the variety on which our groups act. Every such action is translated to a representation-theoretic setup by defining a suitable finite-dimensional algebra in 3.1. We prove certain reduction methods in 3.2 and proceed in 3.3 by classifying all Levi-actions which admit only a finite number of orbits.

#### 3.1 Translations to a quiver settings

The $P$-action on $N_p$

Consider the quiver

\[
Q_p: \begin{align*}
&\begin{array}{cccccccc}
\beta_1 & \beta_2 & \beta_3 & \beta_{p-2} & \beta_{p-1} & \beta_p \\
\alpha_1 & \beta_2 & \alpha_3 & \alpha_{p-3} & \alpha_{p-2} & \alpha_{p-1} & \alpha_p
\end{array} \\
&\begin{array}{cccc}
1 & 2 & 3 & p-2 \\
p-1 & p
\end{array}
\end{align*}
\]
together with the admissible ideal
\[ I_ε := (β^i_j, 1 \leq j \leq p; \ β_{i+1}α_i - α_iβ_i, 1 \leq i \leq p - 1), \]
that is, the ideal generated by all commutativity relations and a nilpotency condition at each loop. The corresponding path algebra \( A(p, x) := KQ_p/I_ε \) with relations is finite-dimensional. Let us fix the dimension vector
\[ d_p := (d_1, \ldots, d_p) := (b_1, b_1 + b_2, \ldots, b_1 + \ldots + b_p) \]
and formally set \( b_0 = 0 \). As explained in Section 3, the algebraic group \( GL_{d_p} \) acts on \( R_{d_p}(Q_p, I_ε) \); the orbits of this action are in bijection with the isomorphism classes of representations in \( rep(Q_p, I_ε) \).

Remark 3.2. The conjugation-action of \( P \) on its nilradical has been classified by L. Hille and G. Röhrle [16]. In particular the number of \( P \)-orbits on \( n_γ \) is shown to be finite if and only if \( p \leq 5 \).

The result is proved by translating the setup to a quiver-theoretic one, as well. The authors consider the quiver

**Theorem 2.1**, yielding the claimed bijection
\[ \Phi : \text{bijection} \]

where \( N_1 \subset N_2 \subset N_3 \subset \cdots \subset N_{p-2} \subset N_{p-1} \subset N_p \subset N \)

The stabilizer \( H \) of \( y_0 \) is isomorphic to \( P \) and the fibre of \( π \) over \( y_0 \) is isomorphic to \( N^{(3)}_p \). Thus, \( R_{d_p}(Q_p, I_ε) \) is isomorphic to the associated fibre bundle \( GL_{d_p} \times^P N^{(3)}_p \) by Theorem 2.1, yielding the claimed bijection \( Φ \).

**Remark 3.2.** The conjugation-action of \( P \) on its nilradical has been classified by L. Hille and G. Röhrle [16]. In particular the number of \( P \)-orbits on \( n_γ \) is shown to be finite if and only if \( p \leq 5 \).

The result is proved by translating the setup to a quiver-theoretic one, as well. The authors consider the quiver

3
together with the relations \( \beta_1 \alpha_1 = 0 \) and \( \beta_i \alpha_i = \alpha_{i-1} \beta_{i-1} \) for \( i \in \{2, \ldots, p-1\} \) which generate an ideal \( I'_p \). They prove that the orbits of the action are in bijection with certain isomorphism classes of \( KQ'_p/I'_p \)-representations and classify the latter.

**The Levi-action on the nilradical**

Consider the quiver \( Q'_L \) of \( p \) vertices, such that there is an arrow \( i \to j \), whenever \( i < j \). For example, \( Q'_L \) is given by

\[
Q'_L: \quad \bullet \longrightarrow \bullet \longrightarrow \bullet \longrightarrow \bullet \longrightarrow \bullet
\]

We define \( \mathcal{A}^L_{p} := KQ'_p/I' \) to be the corresponding finite-dimensional algebra.

As explained in Section 2, the algebraic group \( L_P \cong \text{GL}_b \) acts on \( \text{rep}(Q'_L) \); the orbits of this action are in bijection with the isomorphism classes of representations in \( \text{rep}(Q'_L) \). These are in bijection with the \( L_P \)-orbits in \( n_p \).

**The Levi-action on \( N_p \)**

Consider the quiver \( Q'_L \) defined above and add a loop \( \beta_i \) at each vertex \( 1 \leq i \leq p \); we denote the resulting quiver by \( Q_{L,p} \). Define the ideal \( I \) to be generated by the relations \( \beta_i \beta_i \) for all \( i \). Then the algebra \( A_{L,p} := KQ_{L,p}/I \) is finite-dimensional.

As explained in Section 2 and similarly to the previous case, the algebraic group \( L_P \cong \text{GL}_b \) acts on \( \text{rep}(Q_{L,p}, I) \) and the orbits of this action are in bijection with the isomorphism classes of representations in \( \text{rep}(Q_{L,p}, I) \). These are in bijection with the \( L_P \)-orbits in \( n_p \).

Note that these last constructions are easily generalized to \( x \)-nilpotent matrices.

### 3.2 Reductions

Here, we prove three lemmas in order to compare actions of different parabolics or Levi’s. That is, we show three kinds of reductions which are classical from a Lie-theoretical point of view. Analogues of these statements are available for the \( P \)-action on \( n_p \) in [24].

Given two tuples \((b_1, \ldots, b_p)\) and \((b'_1, \ldots, b'_q)\), we define \((b_1, \ldots, b_p) \leq_c (b'_1, \ldots, b'_q)\) if and only if there is an increasing sequence \( i_1 < \ldots < i_p \), such that \( b_j \leq b'_{i_j} \) for all \( j \).

**Lemma 3.3.** Let \( P \) and \( P' \) be respective parabolic subgroups of \( \text{GL}_n \) and \( \text{GL}_{n'} \) with respective block sizes \( b_p \) and \( b_{p'} \) such that \( b_p \leq_c b_{p'} \). Assume that \( P \) acts infinitely on \( N_p \) (or \( L_P \) acts infinitely on \( N_p \) or \( n_p \), respectively). Then \( P' \) acts infinitely on \( N_{p'} \) (or \( L_{P'} \) acts infinitely on \( N_{p'} \) or \( n_{p'} \), respectively).
Proof. Denote $b_P$ by $(b_1, \ldots, b_p)$ and $b_{\mu'}$ by $(\mu_1', \ldots, \mu_q')$. As seen before, the orbits of each action translate to certain isomorphism classes of representations. Let $(M_i)_{i \in I}$ be an infinite family of non-isomorphic such representations.

Assume first that the acting group is $L_P$. Let $M'_i$ be the corresponding $Q_{L_P}$ (or $Q_{L_{\mu'}}$) representation with dimension vector $\overline{\alpha} \in \mathbb{N}^P$, where $c_{ij} = b_j$ and $c_\lambda = 0$, otherwise. Denote by $S$, the simple module supported at the vertex $i$. Then the family $(N_{ij})_{i \in I}$, where $N_i = M_i \oplus \bigoplus_{j=1}^{P} S_{ij}^{b_j}$, contains pairwise non-isomorphic representations.

Consider now the action of $P$ on $N_P$. Formally set $t_{p+1} := q + 1$. Let $(M'_i)_{i \in I}$ be the naturally induced family of pairwise non-isomorphic representations in $\text{rep}^{\mu}(Q_\mu, I_n)$ defined by

$$(M'_i)_j := \begin{cases} (M_i)_j & \text{if } i_j \leq i < i_{j+1} \\ 0 & \text{if } i < i_1, \end{cases}$$

together with the induced maps $\beta'_{ij} := \beta_{ij}$ (if $i_j \leq i < i_{j+1}$) and $\alpha'_{ij-1,j} := \alpha_{ij}$, further $\alpha'_{ij} := 0$ if $i < i_1$ and $\alpha'_{ij}$ the obvious isomorphism, otherwise.

For $1 \leq i \leq q$, define a representation $U_i$ in $\text{rep}^{\mu}(Q_\mu, I_n)$ via $(U_i)_k = K^{\mathbb{N}^P}$ with injective $\alpha$ and zero $\beta$. Then the representations $N_i := M_i' \oplus \bigoplus_{j=1}^{P} U_i^{b_j}$ form an infinite family of non-isomorphic representations. Hence $P'$ acts infinitely on $N_{P'}$. \(\square\)

We define the transposition $t(\cdot)$ to be the anti-involution of the Lie algebra $\mathfrak{gl}_n$ which is induced by the permutation $(1, n)(2, n-2)\ldots$. It sends the parabolic subgroup $P$ (resp. subalgebra $\mathfrak{p}$) to a parabolic subgroup $P'$ (resp. subalgebra $\mathfrak{p}'$), such that $d_{P_\mu} = (n - d_{P_1}, \ldots, n - d_{P_1}, n)$, and $b_{\mu'} = (b_{p'}, \ldots, b_1)$. Hence we have

**Lemma 3.4.** Let $P$ and $P'$ be parabolics of respective block sizes $b_P = (b_1, \ldots, b_p)$ and $b_{\mu'} = (b_{p'}, \ldots, b_1)$. Then $P$ acts infinitely on $N_P$ (or $L_P$ acts infinitely on $N_P$ or $\mathfrak{n}_P$, respectively) if and only if $P'$ acts infinitely on $N_{P'}$ (or $L_{P'}$ acts infinitely on $N_{P'}$ or $\mathfrak{n}_{P'}$, respectively).

**Lemma 3.5.** Let $P$ and $P'$ be parabolic subgroups of $\text{GL}_n$. Assume that $P$ acts finitely on $N_P$ and that $P' \subset P$. Then $P'$ acts infinitely on $N_{P'}$, where $\mathfrak{p}' = \text{Lie } P'$.

**Proof.** Given a $P'$-orbit $P' \cdot x$ in $\mathfrak{p}'$, we can associate a $P$-orbit in $\mathfrak{p}$ via $P' \cdot x \mapsto P \cdot x$. Since any $P$-orbit meets the Borel subalgebra, this map is surjective. The result follows. \(\square\)

### 3.3 Results for Levi-actions

With standard techniques from quiver-representation theory, we classify the cases in which $L_P$ acts finitely on the nilpotent radical $\mathfrak{n}_P$ and on the nilpotent cone $\mathcal{N}_P$.

**Lemma 3.6.** $L_P$ acts with finitely many orbits on $\mathfrak{n}_P$ if and only if $p \in \{1, 2\}$, that is, if $P$ has at most two blocks.

**Proof.** For $p = 1$, we obtain the action of $\text{GL}_n$ on $\{0\}$ which is clearly finite.

Let $p = 2$, then $Q_{L_2} = A_2$ and, thus, there are only finitely many isomorphism classes of representations for each dimension vector by Gabriel's Theorem \([10]\).

Let $p = 3$, then
are pairwise non-isomorphic representations of dimension vector $(1, 1, 1)$. Thus, an infinite family of non-$L_P$-conjugate matrices is given by

\[
\begin{pmatrix}
0 & 1 & t \\
0 & 0 & 1 \\
0 & 0 & 0
\end{pmatrix}
\]

This induces an infinite family of non-conjugate representations for every remaining case by Lemma 3.3.

\[\square\]

**Lemma 3.7.** $L_P$ acts with finitely many orbits on $N_p$ if and only if $P = \text{GL}_n$ or $P$ is of block sizes $(1, n-1)$ or $(n-1, 1)$.

**Proof.** Whenever $p \geq 3$, infinitely many orbits are obtained from Lemma 3.6 since $n_p \subseteq N_p$.

Let $p = 2$, then an infinite family of pairwise non-isomorphic representations of dimension vector $(2, 2)$ is induced by

\[
\begin{array}{c}
K \\ id \\ \downarrow \\
K \\
\end{array}
\begin{array}{c}
\longrightarrow \\ \longrightarrow \\
\longrightarrow \\
\end{array}
\begin{array}{c}
K \\ id \\ \downarrow \\
K \\
\end{array}
\]

and gives an infinite family of pairwise non-$L_P$-conjugate matrices in $N_p$ right away. Thus, an infinite family is induced whenever both blocks are at least of size 2 by Lemma 3.3.

Let $P$ be of block sizes $(1, n-1)$. Then there are only finitely many $L_P$-orbits in $N_p$: Every representation is of the form

\[
\begin{array}{c}
M_1 \\
\downarrow \\
N_1 \\
\downarrow \\
\cdots \\
\downarrow \\
N_{k-1} \\
\downarrow \\
N_k \\
\downarrow \\
N_{k+1} \\
\downarrow \\
\cdots \\
\downarrow \\
N_l \\
\end{array}
\]

such that $\dim K M_1 = 1$. First case: $f = 0$, then the number of isomorphism classes is finite, since it is reduced to an $A_n$-classification. Second case: $f$ is injective, then the classification can be deduced from the study of the enhanced nilpotent cone [1] Lemma 2.4 and is, thus, finite. By Lemma 3.4, the case $(n-1, 1)$ follows.

If $p = 1$, then $P = \text{GL}_n$ and the finite set of nilpotent Jordan normal forms classifies the orbits.

\[\square\]

**Remark 3.8.** Note that the results of this section still make sense over an arbitrary infinite field $K$. Indeed, since we are working with reductive groups, no issue happen when translating to a quiver-representation context.
In the finite cases, the arguments given in the proofs still hold: $A_n$ is representation-finite over any field and the techniques of [11, Lemma 2.4] do not depend on the base field.

The infinite cases over $K$ all give rise to an infinite family of non-conjugate (over $K$) matrices $(x_t)_{t \in K}$, each with entries in $\{0, 1, t\}$, even after use of Lemma 3.3. If two matrices are non-conjugate over $K$, then they are surely non-conjugate over $K$. So, considering the family $(x_t)_{t \in K}$ is enough to show that the considered case is already infinite over $K$.

4 Covering techniques and $\Delta$-filtered representations

From now on, we will restrict all considerations on the actions of $P$ on $\mathcal{N}_p$ and in particular on $N_p$. Let us call a parabolic subgroup $P$ representation-finite, if its action on $N_p$ admits only a finite number of orbits and representation-infinite, otherwise.

In this section, we define firstly a covering quiver $\tilde{Q}_p$ of $Q_p$ together with an admissible ideal. The study of this quiver provides a finiteness criterion for the whole category $\text{rep}(Q_p, I_x)$ in Proposition 4.2. The rest of the section is devoted to the study of analogues of $\text{rep}^{inj}(Q_p, I_x)$ in the covering context. In subsection 4.2 this yields several infinite families of non-isomorphic indecomposable representations. In subsections 4.3, 4.4 we make use of the theory of quasi-hereditary algebras and $\Delta$-filtered modules. This allows to relate some of our subcategories of modules of the form $\text{rep}^{inj}$ to “whole” categories of representations of smaller quivers.

4.1 The covering

By techniques of Covering Theory [11, §3], it is useful to look at the covering algebra first. We sketch this idea and discuss first results, now. Note that our quiver algebras with relations should be thought as locally bounded $K$-categories in [11].

In order to apply results of Covering Theory, we consider the infinite universal covering quiver of $\mathcal{H}(p, x)$ (at the vertex $p$), which we call $\tilde{Q}_p$:

\[\begin{array}{cccccccc}
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\beta_1 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_{p-3} & \alpha_{p-2} & \alpha_{p-1} & \beta_p \\
\beta_2 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_{p-3} & \alpha_{p-2} & \alpha_{p-1} & \beta_p \\
\beta_3 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_{p-3} & \alpha_{p-2} & \alpha_{p-1} & \beta_p \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\beta_1 & & & & & & & \\
\beta_2 & & & & & & & \\
\beta_3 & & & & & & & \end{array}\]
Let  be the induced ideal, generated by all nilpotency relations (for the loops at the vertices) and all commutativity relations; we see that the fundamental group is given by  which acts by vertical shifts. The universal covering algebra will be denoted by . The special case where  is denoted by . In order to classify the action of  on  it is useful to study the category (Lemma 3.1). It’s pendant in the covering context is given by the representation category of those -representations of which all horizontal maps are injective, we call it .

The quiver is locally bounded, so that many results of Covering Theory [11] can be applied. The universal covering functor  induces a “push-down”-functor between the representation categories [3, §3.2] which has the following nice properties:

**Proposition 4.1.**

1. sends indecomposable non-isomorphic representations, which are not -translates, to indecomposable non-isomorphic representations.

2. If  has dimension vector  then  has dimension vector  where  is the sum of  for .

3. .

4. Let  and  be as in 2. Then  induces an injective linear map  which has the following nice properties:

**Proof.** The first property follows from [11] Lemma 3.5. The other three are clear from the construction of  in [3, §3.2].

By [11] Theorem 3.6, if the algebra  is locally representation-finite (that is, for each vertex  the number of -representations  with  is finite), then the algebra  is representation-finite. For example, we can use the BHV-list (see, for example, [15]) in order to find infinitely many non-isomorphic indecomposable -representations and know that these yield infinitely many non-isomorphic indecomposable -representations via the functor .

It is also useful to define a truncated version of .

\[
\text{\text{\begin{tabular}{c}
\end{tabular}}}
\]

\[
\text{\text{\begin{tabular}{c}
\end{tabular}}}
\]
of $n$ rows and $p$ columns. Define $\tilde{I}_{p,n}(x)$ to be the ideal generated by all commutativity relations and by the relation that the composition of $x$ vertical maps equals zero. Further, define $\mathcal{A}(p, x)_n := K\hat{Q}_{p,n}/\tilde{I}_{p,n}(x)$. Representations are given as tuples $(M_{i,j})_{1 \leq i \leq n, 1 \leq j \leq p}$ together with maps $\alpha_{k,l} : M_{k,l} \to M_{k,l+1}$ and $\beta_{k,l} : M_{k,l} \to M_{k+1,l}$ fulfilling $\beta_{k,l+1} \circ \alpha_{k,l} = \alpha_{k+1,l} \circ \beta_{k,l}$. If $x = n$, then define $\mathcal{A}(p, x)_n := \mathcal{A}(p, x)_n$ and $\tilde{I}_{p,n} := \tilde{I}_{p,n}(x)$.

We decide representation-finiteness concretely for $\mathcal{A}(p, x)$ below. In case the universal covering algebra is locally representation-finite, the algebra $\mathcal{A}(p, x)$ is representation-finite, as well [1] If the covering algebra is representation-infinite, then $\mathcal{A}(p, x)$ is as well representation-finite via the functor $F_\lambda$. Note that the following result has been stated in [2], we include it for completeness in all detail.

**Proposition 4.2.** The algebra $\mathcal{A}(p, x)$ is representation-finite if and only if $p = 1$ or $x = 1$ or $(p, x) \in \{(2, 2), (2, 3), (3, 2)\}$.

**Proof.** Let $p = 1$ and $x$ be arbitrary. In this case, the indecomposable representations are (up to isomorphism) induced by the Jordan normal forms of $x$-nilpotent matrices. Therefore, there are only finitely many isomorphism classes, corresponding to single Jordan blocks.

Let $x = 1$ and $p \geq 2$. In this case, the classification translates to an $A_p$-classification case. Thus, there are only finitely many isomorphism classes of indecomposables.

Let $p = 2$ and $x = 2$. We show that the algebra $\mathcal{A}(2, 2)$ is locally representation-finite and this implies that $\mathcal{A}(2, 2)$ is representation-finite. Let $M$ be an indecomposable finitely-generated $\mathcal{A}(2, 2)$-representation. Then $M$ can be seen as a representation of $\hat{Q}_{p,n}$ for some sufficiently large $n$.

By knitting, we can compute the Auslander-Reiten quiver of $\mathcal{A}(2, 2)_n$. It turns out that it has a middle part which is repeated in a cyclic way up to a shift by the $\mathbb{Z}$-action. Its initial, middle and terminal part are depicted in Appendix A.1. There, we denote by $M^{(h)}$ the $\mathcal{A}(2, 2)_n$-representation obtained by $h$-times shifting the $\mathcal{A}(2, 2)_n$-representation $(h \in \{1, 2, 3\}) M$ from bottom to top. We see that, up to $\mathbb{Z}$-action, each of the isomorphism classes of indecomposables of $\mathcal{A}(2, 2)_n$ have a representant in the middle part of the Auslander Reiten quiver. As a consequence, the same holds for the representations of $\mathcal{A}(2, 2)$ so the algebra is locally representation finite.

Let $p = 3$ and $x = 2$. In the same manner as in the case $p = 2$, $x = 2$, one shows that $\mathcal{A}(3, 2)$ is locally representation-finite. The middle part of the Auslander-Reiten-quiver of $\mathcal{A}(3, 2)_n$ is depicted in the Appendix A.2.

Let $p = 2$ and $x = 3$. Again as in the two previous cases, one shows that $\mathcal{A}(2, 3)$ is locally representation-finite. The middle part of the Auslander-Reiten-quiver of $\mathcal{A}(2, 3)_n$ is depicted in the Appendix A.3.

For each remaining case, we find a full subquiver of the quiver $\hat{Q}_{p,n}$ in the BHV-list (see below for the concrete quivers), which fulfills the relations induced by $\tilde{I}_{p,n}(x)$. Via the functor $F_\lambda$, we obtain infinite families of non-isomorphic representations for each such algebra $\mathcal{A}(p, x)$.
Note that this is a very general representation-theoretic approach to understand the algebra $\mathcal{A}(p, x)$ better. In order to solve our classification problem, it does not suffice, since the found representations do not necessarily come up in the classification: they might not have injective maps corresponding to all arrows $\alpha_1, \ldots, \alpha_p$.

From now on, we focus on the case $x = n$.

### 4.2 Infinite actions via covering

Via the covering functor, every representation in $\text{rep}^\text{inj}(\hat{Q}_p, n, \hat{I}_p, n)$ induces a representation in $\text{rep}^\text{inj}(Q_p, I_p)$. In order to examine the number of isomorphism classes in $\text{rep}^\text{inj}(Q_p, I_p)$, we can begin by considering isomorphism classes in $\text{rep}^\text{inj}(\hat{Q}_p, n, \hat{I}_p, n)$ of “expanded” dimension vectors, which sum up to $d_P$, thus.

**Proposition 4.3.** Assume that $K$ is an arbitrary infinite field. The number of $P$-orbits in $N_p$ is infinite if $b_P = (b_1, \ldots, b_p)$ or $b_P = (b_p, \ldots, b_1)$ appears in Figure B.1.

**Proof.** First, let us assume that $K$ is algebraically closed. We begin by proving infiniteness for the minimal cases (painted in blue in the diagram in B.1). This is done by pointing out some infinite families in $\text{rep}^\text{inj}(\hat{Q}_p, n, \hat{I}_p, n)$. This provides some infinite families in $\text{rep}^\text{inj}(Q_p, I_p)$ thanks to Proposition 4.1 and the result follows in these cases by Lemma 3.1.

Then the use of Lemmas 3.5, 3.3 is depicted in the diagram in B.1 to produce further infinite cases. The corresponding symmetric cases are infinite by Lemma 3.4. Induced by the quiver $\tilde{D}_4$, we find an infinite family for block sizes $(2, 2, 2)$, see Figure 1. The remaining cases can be deduced from the tame quiver $\tilde{E}_6$ and are depicted in Figure 2. For these to be admissible, one has to show the following claim:

**Claim 4.4.** Whenever $a, b, c$ or $e$ are oriented from a smaller space to a bigger one in the $\tilde{D}_4$- or $\tilde{E}_6$-representations of Figures 1 and 2 then these maps are injective maps. In particular, all the corresponding families belong to $\text{rep}^\text{inj}(\hat{Q}_p, n, \hat{I}_p, n)$.

**Proof.** The case $1 \to 2$, such that no arrow ends in 1. In this case, the kernel of $\alpha$ is a subrepresentation and any complement is a submodule. The result then follows since our one-parameter family is made of indecomposables.

The second case is $2 \to 3$ in the $\tilde{E}_6$-case. The orientation is given by $1 \to 2 \to 3$ (note that our claim also holds true in general). By our previous considerations, $a$ is
injective. Then \( \ker(b \circ a) \to \ker(b) \) is a subrepresentation which has complements being a submodule. Once again, the indecomposability allows us to conclude. □

Let us assume next that \( K \) is only an infinite field. The infinite families \((M_t)_{t \in K}\) over \( \overline{K} \) yielded by Figures 1 and 2 can all be expressed in \( R^{a_0}(\hat{Q}_p, \hat{I}_n) \) with entries in \( \{0, 1, t\} \). Then they give rise to families of nilpotent matrices \((x_t)_{t \in K}\) with the same properties and the last argument of Remark 3.8 apply. □

**Remark 4.5.** It is worth noting that our infinite families arising in Tables 1 and 2 all correspond to simpler families in \( \text{rep}(\overline{Q}_{p,n-1}, \overline{I}_{p,n-1}) \) through Theorem 4.8 and Proposition 4.10. Up to symmetry and bending of some arrows, they all are of the form...
III.2.4. For $(S(x), \ldots, S(y))$ together with identity and zero maps, accordingly. Given a simple representation $V$ in $[9]$ and $[6]$, we define $\Delta_4$ and the sequence is $0 \subseteq D(i, p) \subseteq \cdots \subseteq D(i, j + 1) \subseteq D(i, j)$ with quotients $S(i, x), j \leq x \leq p$. The module $D(i, j)$ is thus a maximal factor module of $P(i, j)$ with composition factors of the form $S(k, l)$ with $(k, l) \leq (i, j)$.

The representations $\Delta := \{D(i, j) \mid (i, j) \in V\}$ are called standard representations. We define $\mathcal{F}(\Delta)$ to be the category of all $\Delta$-filtered modules, that is, modules $M$ which admit a filtration $\{0\} = M_k \subseteq M_{k-1} \subseteq \cdots \subseteq M_1 \subseteq M_0 = M$ for some $k$ and such that for every $i$, there is a module $D \in \Delta$, such that $M_i/M_{i-1} \cong D$.

The costandard representations $\nabla := \{\nabla(i, j) \mid i, j\}$ and the category $\mathcal{F}(\nabla)$ are defined dually and are given by

$$\nabla(i, j)_{k,l} = \begin{cases} K & \text{if } k \leq i \text{ and } l = j, \\ 0 & \text{otherwise,} \end{cases}$$

together with the obvious maps.

4.3 $\Delta$-filtrations

We now investigate in more details representations $\operatorname{rep}^{\text{in}}(\mathcal{Q}_{p,n}, \mathcal{I}_{p,n})$. This category turns out to be a certain category of $\Delta$-filtered modules. We describe this now, following the constructions in [9] and [6].

We define $V := \{1, \ldots, n\} \times \{1, \ldots, p\}$, which equals the set of vertices of $\mathcal{Q}_{p,n}$, the first entry increases from top to bottom and the second entry increases from left to right. A total ordering on $V$ is given by

$$(i, j) \leq (k, l) \iff i < k \text{ or } (i = k \text{ and } j \leq l).$$

For $(i, j) \in V$, let $S(i, j)$ be the standard simple representation at the vertex $(i, j)$.

The projective indecomposables $P_{i,j}$ of $\mathcal{A}(p)$, are parametrized by $V$ and are given by $P(i, j)_{k,l} = \begin{cases} K & \text{if } k \geq i \text{ and } l \geq j, \\ 0 & \text{ otherwise,} \end{cases}$ together with identity and zero maps, accordingly. Given a simple representation $S(i, j)$, the epimorphism $f : P(i, j) \to S(i, j)$ is a projective cover of $S(i, j)$ by [2] III.2.4.

Let $D(i, j)$ be the maximal quotient of $P(i, j)$ which admits a filtration of simple representations $S(k, l)$, such that $(k, l) \leq (i, j)$. Then

$$D(i, j)_{k,l} = \begin{cases} K & \text{if } i = k \text{ and } l \geq j, \\ 0 & \text{ otherwise,} \end{cases}$$

and the sequence is $0 \subseteq D(i, p) \subseteq \cdots \subseteq D(i, j + 1) \subseteq D(i, j)$ with quotients $S(i, x), j \leq x \leq p$. The module $D(i, j)$ is thus a maximal factor module of $P(i, j)$ with composition factors of the form $S(k, l)$ with $(k, l) \leq (i, j)$.

The representations $\Delta := \{D(i, j) \mid (i, j) \in V\}$ are called standard representations. We define $\mathcal{F}(\Delta)$ to be the category of all $\Delta$-filtered modules, that is, modules $M$ which admit a filtration $\{0\} = M_k \subseteq M_{k-1} \subseteq \cdots \subseteq M_1 \subseteq M_0 = M$ for some $k$ and such that for every $i$, there is a module $D \in \Delta$, such that $M_i/M_{i-1} \cong D$.

The costandard representations $\nabla := \{\nabla(i, j) \mid i, j\}$ and the category $\mathcal{F}(\nabla)$ are defined dually and are given by

$$\nabla(i, j)_{k,l} = \begin{cases} K & \text{if } k \leq i \text{ and } l = j, \\ 0 & \text{otherwise,} \end{cases}$$

together with the obvious maps.
Proposition 4.6.

\[ \mathcal{F}(\Delta) = \{ M \in \text{rep}(\hat{Q}_{p,n}, \hat{T}_{p,n}) \mid \text{Hom}(S(i,j), M) = 0 \text{ for } (i, j) \in V, j < p \} \]
\[ \mathcal{F}(\nabla) = \{ M \in \text{rep}(\hat{Q}_{p,n}, \hat{T}_{p,n}) \mid M_{0_{ij}} \text{ is surjective for all } k, l \} \]

Proof. We show that \( \text{rep}^{\text{ini}}(\hat{Q}_{p,n}, \hat{T}_{p,n}) \subset \mathcal{F}(\Delta) \subset \{ M \mid \text{Hom}(S(i,j), M) = 0 \text{ for } j < p \} \subset \text{rep}^{\text{ini}}(\hat{Q}_{p,n}, \hat{T}_{p,n}) \); the proof for \( \mathcal{F}(\nabla) \) is dual.

The first inclusion can be shown as follows: Let \( M \in \text{rep}^{\text{ini}}(\hat{Q}_{p,n}, \hat{T}_{p,n}) \). We show that \( M \) has a \( \Delta \)-filtration inductively:

Define \( M_0 = M \). If \( M_i \) has been defined, then without loss of generality, we assume that \( (M_i)_{k,l} = K_{a_{ij}} \) for all \( k, l \). Define \( x \) to be the minimal integer, such that \( (M_i)_{x,n} \neq 0 \) (then \( (M_{i-1})_{x-1,n} = 0 \)) and \( y \) to be the minimal integer, such that \( (M_i)_{x,y} \neq 0 \) (then \( (M_{i-1})_{x-1,1} = 0 \) or \( y = 1 \)). Then define \( M_{i+1} \) to be the module

\[
(M_{i+1})_{k,l} = \begin{cases} 
K_{a_{x,y}}^{-1} & \text{if } k = x \text{ and } l = y, \\
\alpha_{k,l-1} \circ \cdots \circ \alpha_{x,y}(K_{a_{x,y}}^{-1}) & \text{if } k = x \text{ and } l > y, \\
K_{a_{ij}} & \text{otherwise,}
\end{cases}
\]

together with the induced natural maps. Then \( M_i/M_{i+1} \equiv D(x,y) \) and by induction \( M \) is \( \Delta \)-filtered.

The second inclusion is a consequence of the fact that \( \text{soc } D(i,j) = D(i,j)_{i,p} \).

Let \( M \) be a module, such that one horizontal map is not injective, say \( \alpha_{i,j} \) with \( i \) maximal. Since \( \alpha_{i+1,j} \) is injective, it follows from the commutativity relation that \( \ker(\alpha_{i,j}) \subset \ker(\beta_{i,j}) \). So \( \ker(\alpha_{i,j}) \) is a submodule of \( M \) isomorphic to a sum of copies of \( S(i,j) \). Hence, the last inclusion follows. \( \square \)

The algebra \( \mathcal{F}(\Delta) \) is strongly quasi-hereditary \([23]\), since \( \text{End}_K(D(i,j)) \equiv K \) for all \( (i,j) \in V \) and since the projective dimension of \( D(i,j) \in \Delta \) is at most 1: If \( i = n \), then \( D(i,j) \) is projective. Otherwise, a projective resolution is given by

\[ 0 \to P(i+1, j) \to P(i,j) \to D(i,j) \to 0. \]

In a similar way, the costandard modules have injective dimension at most 1.

### 4.4 \( \mathcal{F}(\Delta) \) via a torsion pair

In the following, we translate the category \( \mathcal{F}(\Delta) \) to the torsionless part of a certain torsion pair in a similar manner as in V. Dlab’s and C. M. Ringel’s work \([9]\). We refer to \([2]\) Chapter VII for basic definitions of Tilting Theory.

Define for each \( (i,j) \in V \) a module

\[ T(i,j)_{k,l} = \begin{cases} 
K & \text{if } k \leq i \text{ and } l \geq j, \\
0 & \text{otherwise.}
\end{cases} \]

Define \( T := \bigoplus_{i,j} T(i,j) \).

Lemma 4.7. 1. \( \mathcal{F}(\Delta) \cap \mathcal{F}(\nabla) = \text{add } T \) equals the set of all Ext-injective modules.
2. The module $T = \bigoplus_{i,j \in V} T(i, j)$ is a tilting module.

3. The pair $(\mathcal{F}(\nabla), \mathcal{H}(T))$, where

$$\mathcal{H}(T) := \{ Y \in \text{rep}(\hat{Q}_{p,n}, \hat{P}_{p,n}) | \text{Hom}(T, Y) = 0 \},$$

is a torsion pair.

**Proof.** We know $T(i, j) \in \mathcal{F}(\Delta) \cap \mathcal{F}(\nabla)$ by Proposition 4.6. By [9], this is Ext-injective, while there are exactly $p \cdot n$ indecomposable Ext-injective representations. Thus, add $T = \mathcal{F}(\Delta) \cap \mathcal{F}(\nabla)$. Since the projective dimension of every standard representation is at most 1, the module $T$ is a tilting module by [9] Lemma 4.1 ff and the pair $(\mathcal{F}(\nabla), \mathcal{H}(T))$ is a torsion pair by [9] Lemma 4.2.

Let $\varphi$ be the endofunctor of $\text{rep}(\hat{Q}_{p,n}, \hat{P}_{p,n})$ defined by $\varphi(M) = M/\text{Im}(\eta_T(M))$, where $\eta_T(M)$ is the trace of $M$ along $T$, that is, the largest submodule of $M$ which lies in add $T$. Let $\mathcal{F}(\Delta)/(T)$ be the category with the same objects as $\mathcal{F}(\Delta)$, and morphisms given by residue classes of maps in $\mathcal{F}(\Delta)$: two maps $f, g : X \to Y$ are contained in the same residue class if and only if $f - g$ factors through a direct sum of copies of $T$.

**Theorem 4.8.** [9 Theorem 3] The functor $\varphi$ induces an equivalence between $\mathcal{F}(\Delta)/(T)$ and $\mathcal{H}(T)$.

Since the indecomposable representations in $\mathcal{F}(\Delta)/(T)$ are exactly the indecomposable representations in $\mathcal{F}(\Delta)$ except for the indecomposable representations contained in add $T$, [9] we obtain the following corollary.

**Corollary 4.9.** The categories $\mathcal{H}(T)$ and $\mathcal{F}(\Delta)$ have the same representation type.

Thus, the knowledge of the category $\mathcal{H}(T)$ gives further insights into $\mathcal{F}(\Delta)$. We discuss the detailed structure of the former now.

**Proposition 4.10.** $\mathcal{H}(T) \cong \text{rep}(\hat{Q}_{p,n-1}, \hat{P}_{p,n-1})$

**Proof.** We show that the representations in $\mathcal{H}(T)$ are exactly those representations $M \in \mathcal{F}(\Delta)$, such that $M_{1,j} = 0$ for all $j$.

Let $M \in \mathcal{H}(T)$. Then $M = \varphi(N)$ for some $N \in \mathcal{F}(\Delta)$, since $\varphi$ is surjective. Let $d := d_{i,j}$ be the left-most non-zero entry of $\dim N$ in the first row. Let $v$ be a non-zero element of $M_{1,j}$. It generates a submodule $T(t_i, j)$ for some $1 \leq t_i \leq n$. By taking the quotients by $T(t_i, j)$, one obtains a representation $N/\mathcal{F}(\Delta)$, such that $\dim_k N_{1,j} < \dim_k N_{1,j}$. Inductively, we see that the functor $\varphi$ deletes all vector spaces in the first row of $M$. Thus, $M_{1,j} = 0$ for all $j \in \{1, \ldots, p\}$.

Let $M$ be a representation of $\text{rep}(\hat{Q}_{p,n}, \hat{P}_{p,n})$, such that $M_{1,j} = 0$. Since $\text{Top}(T(i,j)) = S(1, j)$ for all $i$, we then have $\text{Hom}(T, M) = 0$.

**Proposition 4.11.** There are only finitely many isomorphism classes of indecomposable representations in $\mathcal{F}(\Delta) = \text{rep}^{p,n}(\hat{Q}_{p,n}, \hat{P}_{p,n})$ if and only if $p = 1$ or $n \leq 2$ or $(p,n) \in \{(2,3), (3,3), (4,3), (2,4), (2,5)\}$.
Proof. Since the representation type of $\mathcal{F}(\Delta) = \text{rep}^{\text{inj}}(\hat{Q}_p, \hat{T}_p)$ is the same as the one of $\mathcal{H}(T)$, the proof follows from [5], where the representation type of $\mathcal{A}(p)_n$ is discussed. This last result is also easily recovered by arguments similar to the proof of Lemma 4.2.

We end the examination of $\mathcal{H}(T)$ by considering a particular example for which we discuss $\mathcal{H}(T)$ by means of the Auslander-Reiten quiver of $\mathcal{A}(p)_n$.

Example 4.12. Let $p = 2$ and $n = 3$. The Auslander-Reiten quiver of $\mathcal{A}(2)_3$ is given by

![Auslander-Reiten quiver](image)

The modules $T(i, j)$ are marked by bold dimension vectors; and the modules which belong to the category $\mathcal{H}(T)$ are marked by boxes.

5 Finite cases

In this section, we prove finiteness of all remaining cases which do not appear in (and are not symmetric to one case of) diagram B.1 cf. Proposition 4.3.

Theorem 5.1. The parabolic $P$ acts finitely on $\mathcal{K}_p$ if $b_P = (b_1, \ldots, b_p)$ or $b_P' = (b_p, \ldots, b_1)$ appears in diagram B.2.

Via reductions of Section 5.2 as visualized in diagram B.2 the following lemma directly proves Theorem 5.1.

Lemma 5.2. Let $b_P \in \{(5, k, 1), (1, 3, k, 1), (3, 1, k, 1), (1, 1, 1, k, 1)\}$. Then the number of isomorphism classes in $\text{rep}^{\text{inj}}(Q_p, T_p)(d_p)$ is finite.

The remainder of the section is dedicated to proving Lemma 5.2. Note that some of the remaining cases are known to be finite. Namely, the case $b_P = (1, 1, 1, 1, 1)$ is proved to be finite by L. Hille and G. Röhrle in [16]. Also, the case $b_P = (5, k)$ has been shown to be finite by S. Murray [20]. Independently, the cases $b_P \in \{(1, n-1), (2, n-2)\}$ have been proved to be finite by the second author and L. Evain in [7].

The proof of Lemma 5.2 is structured as follows: We begin by re-proving Murray’s case $b_P = (5, k)$ in Subsection 5.3 and make use of certain techniques which will be introduced in Subsections 5.1 and 5.2. Afterwards, we generalize these results to the four cases of Lemma 5.2 in Subsection 5.4. Only elementary techniques of linear algebra are used so that everything holds over an arbitrary field $K$. 

18
5.1 Notation

We introduce first the combinatorial data which is the central object of study in the remaining of this section. We associate to any partition \( \lambda := (\lambda_1 \geq \cdots \geq \lambda_g) \) of \( n \) the corresponding left-justified Young diagram with \( \lambda_i \) boxes in the \( i \)-th row. The box in the \( i \)-th row and the \( j \)-th column is called box \((i, j)\).

**Definition 5.3.** Given \( h \in \mathbb{N}^* \), a labeled Young diagram of \( h \)-tuples is a Young diagram together with an \( h \)-tuple \((\gamma_1^{i,j}, \ldots, \gamma_h^{i,j})\) associated to each box \((i, j)\) in the Young diagram.

Given an element of \( \text{rep}_{\text{inj}}^{\text{rep}}(Q_2, I_n) \) of dimension \((l, k)\)

\[
	ext{we find a corresponding labeled Young diagram as follows.}
\]

We choose a basis of \( V \) (resp. \( U \)) such that \( f \) (resp. \( f|_U \)) is in Jordan normal form with partition \( \lambda = (\lambda_1 \geq \cdots \geq \lambda_g) \) (resp. \( \mu = (\mu_1 \geq \cdots \geq \mu_h) \)) of \( k \) (resp. \( l \)) in a basis of \( V \) (resp. \( U \)) the form \((v_i, j)^{\lambda_i}_{\leq g} \) (resp. \((u_m, t)^{\mu_m}_{\leq h}\)). That is,

\[
f(v_{i,j}) = \begin{cases} v_{i,j-1} & \text{if } j \geq 2 \\ 0 & \text{else} \end{cases}, \quad f(u_{m,t}) = \begin{cases} u_{m,t-1} & \text{if } t \geq 2 \\ 0 & \text{else} \end{cases}.
\]

For each \( i \), we set \( v_i := v_{i,L} \) (resp. \( u_m := u_{m,M} \)). We consider the decomposition \( u_m = \sum_{i,j} \gamma^{m}_{i,j} v_{i,j} \). Then the corresponding labeled Young diagram is the Young diagram associated to \( \lambda \) together with an \( h \)-tuple \( (\gamma_1^{i,j}, \ldots, \gamma_h^{i,j}) \in W := K^h \) associated to each box \((i, j)\).

**Example 5.4.** Let \( \lambda := (4, 2, 1) \) and \( \mu := (2, 1) \). Assume that \( u_1 = 2v_{1,2} - 3v_{1,1} - 4v_{2,2} + 5v_{2,1} + v_{3,1}, u_2 = 6v_{1,1} - 7v_{2,1} + v_{3,1} \), then we obtain the labeled Young diagram

\[
\begin{array}{cccc}
(-3, 6) & (2, 0) & (0, 0) \\
(5, -7) & (-4, 0) \\
(1, 1)
\end{array}
\]

The \( \gamma^{m}_{i,j} \) are not unique in general. However, since \( U = \langle f^t(u_m) \rangle_{t,m} \), they are enough to recover the isomorphism class of the original representation. We will prove that, up to \( GL(U) \times GL(V) \)-conjugacy, the \( \gamma^{m}_{i,j} \) can all be taken in \( \{0, 1\} \) whenever \( l \leq 5 \). This implies that there are finitely many non-isomorphic representations in this case.

5.2 Base changes

The aim of this subsection is to introduce some combinatorial elementary moves on labeled Young diagrams which will be used in §5.6 and §5.7. The procedure will be to
reduce the labeled Young diagram, that is, we will use some non-zero entries \( \gamma_{i,j}^m \) as pivots in order to kill (that is, to bring to 0 by a base change) some other entries. The following proposition is well known \([17]\).

**Proposition 5.5.** Performing a base change of the form

\[
\left( v_{i,j} \leftarrow \sum_{i',j'} \omega_{i,j}^{i',j} v_{i',j'} \right)_{i,j} \quad \forall i, j, i', j' : \omega_{i,j}^{i',j} \in K
\] (2)

keeps \( f \) in Jordan normal form if and only if

\[
\omega_{i,j}^{i',j} = \begin{cases} 
0 & \text{if } i' > j \text{ or } \lambda_i - j > \lambda_{i'} - j' \\
\omega_{i,j}^{i',j-1} & \text{if } 2 \leq i' \leq j \text{ and } \lambda_i - j \leq \lambda_{i'} - j' 
\end{cases}
\] (3)

Note that the \( (\omega_{i,j}^{i',j})_{i',j} \) are enough to determine all the \( (\omega_{i,j}^{i',j})_{i',j} \) thanks to the condition \( 4 \). In particular we can afford setting \( \omega_{i,j}^{i',j} := \omega_{i,j}^{i,j} \) and writing the base change \( 2 \) via \( (v_i \leftarrow \sum_{i',j} \omega_{i,j}^{i',j} v_{i',j})_i \). A bit more generally, given indices \( j_i \) for each \( i \), we define a base change of the form \( 2 \) by the formula

\[
\left( v_{i,j} \leftarrow \sum_{i',j'} \omega_{i,j}^{i',j} v_{i',j'} \right)_{i,j}, \quad \text{setting } \omega_{i,j}^{i',j} := \begin{cases} 
\omega_{i,j}^{i',j} + \delta_{i,j} & \text{if } 1 \leq i' + j_i - j \leq \lambda_{i'} \\
0 & \text{else.}
\end{cases}
\]

Upon above notation and for any fixed \( i, j \), the base changes of the following forms always satisfy the condition \( 3 \)

\[
M_i : \quad v_i \leftarrow \omega v_i, \quad \text{with } \omega \in K^*
\]

\[
C_{i,j} : \quad v_{i,j} \leftarrow v_{i,j} + \sum_{i',j'} \omega_{i',j'} v_{i',j'}, \quad \forall i', j' : \omega_{i',j'} \in K
\]

(4)

and other \( v_i \) (\( i' \neq i \)) unchanged. The same holds for the following base change for any \( (i_0, j_0), (i_1, j_1) \) such that \( i_0 < i_1 \) and \( j_0 > j_1 \).

\[
B_{(i_0, j_0); (i_1, j_1)} : \quad \begin{pmatrix} v_{i_0,j_0} & v_{i_0,j_1} \\ v_{i_1,j_0} & v_{i_1,j_1} \end{pmatrix} \leftarrow \begin{pmatrix} v_{i_0,j_0} + \omega v_{i_0,j_1} \\ v_{i_1,j_0} - \omega v_{i_0,j_1} \end{pmatrix}, \quad \omega \in K
\]

**Tools 5.6.** These base changes have interesting effects in our situation. We explain some of them on the coefficients \( \gamma_{i,j}^m \) and pictorially on diagrams drawn as in \([5,4]\).

**M** \( M_i \) allows to multiply \( (\gamma_{i,j}^m)_{m,j} \) by \( \frac{1}{\omega} \). Pictorially, this means that we can multiply row \( i \) on a diagram by any non-zero scalar.

**C** Assume that \( \gamma_{i,j}^m = 1 \) for some \( m, i, j \) and \( \gamma_{i',j'} = 0 \) for any \( j' > j \). A base change of the form \( C_{i,j} \) allows to set \( \gamma_{i',j'} \) to 0 for any \( (i',j') \neq (i,j) \) such that \( i' \leq i, j' \leq j \) without modifying \( \gamma_{i',j'} \) for any other couple \( (i',j') \) (take \( \omega_{i',j'} := \gamma_{i',j'}^{0,j} \) in
Moreover, if \( \gamma^m_{i,j}' = 0 \) for any \( j', m' \neq m \), then the \( \gamma^m_{i,j}' \) are not modified for any \( i', j' \) and \( m' \neq m \). Pictorially, this means the following. Assume that the rightmost non-zero tuple in row \( i \) appears in column \( j \) and is of the form \((*, *, \ldots, 1, *, \ldots, *)\), then the \( m \)-th entry of any box in the quadrant northwest to \((i, j)\) can be killed while the tuples outside this quadrant are unchanged. Moreover, if all the \( m' \)-entries (for some \( m' \neq m \)) are zero in row \( i \), then no \( m' \)-th entry is modified in the labeled Young diagram.

B Assume that \((i_0, j_0), (i_1, j_1)\) are such that \(i_0 < i_1, j_0 > j_1, \gamma_{i,j} = 0\) for any \( i, j \) such that \( i = i_0, j \notin \{1, j_0\} \) or \( i = i_1, j \notin \{1, j_1\} \). Assume also that \( \gamma_{i_0,j_0} = \gamma_{i_1,j_1} \). A base change of the form \( B_{(i_0,j_0),(i_1,j_1)} \) preserves all the tuples \( \gamma_{i,j} \) except when \( i = i_0, j = 1 \) where the base change implies \( \gamma_{i_0,1} \leftarrow \gamma_{i_0,1} + \omega \gamma_{i_1,1} \).

Naturally, Proposition 5.5 and subsequent remarks also hold with \((u_m)_m \) instead of \((v_{i,j})_i,j \) and \( \mu \) instead of \( A \). The effect on the \( \gamma^m_{i,j} \) is easier to describe. For instance, a base change of the form \( \left( u_m \leftarrow \sum_{m'} \omega^m_{m'} u_{m'} \right) \) induces an action on \( W \), the space of tuples, as follows: for each \((i, j)\) we get \( \gamma_{i,j} \leftarrow A \gamma_{i,j} \) where \( A \) is the \( h \times h \) matrix whose entry in line \( m \) and column \( m' \) is \( \omega^m_{m'} \).

We describe below a few base changes of interest which always satisfy condition 3. Given \( s \in [1, h] \), we define \( W_s \) as the subspace of \( W \) generated by the first \( s \) vectors of the canonical basis \((e_1, \ldots, e_h)\) and set \( W_0 := \{0\} \). Given \( j \), define

\[
D_j : \left( u_m \leftarrow \sum_{m'} \omega^m_{m'} u_{m'} \right)_m \text{ with } \begin{cases} S = [m_1, \ldots, m_2] := \{m | \mu_m = j\}, \\ A := (\omega^m_{m'})_{m,m' \in S} \in \text{GL}_h, \\ \forall S \notin S, Ae_s = e_s, \forall S \in S, Ae_s \in W_{m_2}. \end{cases}
\]

(5)

Given \( m \) and \( j < \mu_m \), we define

\[
E_{m,j} : \left( u_m \leftarrow u_m + \omega^m_{m'} u_{m'} \right)_{m' \mid \mu_{m'} > j}, \quad \forall m' : \omega^m_{m'} \in K
\]

and such that every remaining \( u_{m'} \) is unchanged.

Tools 5.7. These base changes allow the following actions on the coefficients \( \gamma^m_{i,j} \):

D Given \((i_m, j_m), \ldots, (i_{m+p}, j_{m+p})\) such that the \( p \) different \((\xi S)\)-tuples \((\gamma^m_{i,j})_{m \in S}\) are linearly independent, \( D_j \) allows to set each \((\gamma^m_{i,j})_{m \in \{1, m_2\}} \in W_{m_2} \) to \( e_s \in W_{m_2} \), stabilizing the \( e_{s'} \) for \( s' \notin S \).

E Given \( m \), assume that there exists exactly one index \( i \) such that \( \gamma^m_{i,j} \) is non-zero (note that \( \gamma^m_{i,j} = 0 \) whenever \( j' > \mu_m \)). Then a base change of the form \( E_{m,j} \) \((j < \mu_m)\) allows to kill the tuple \( \gamma_{i,j} \), without modifying any \( \gamma_{i',j'} \) with \( j' \not\equiv j \) (set \( \omega_{m'} := \gamma^m_{i,j}/\gamma^m_{i,j} \)). Pictorially, if there is a single tuple with non-zero \( m \)-th entry in the column \( \mu_m \), then we can kill any tuple lying on the same row left of this one without modifying tuples on columns right to the annihilated one.

5.3 Reductions

With the combinatorial tools of the previous subsection, the game is to reduce every possible diagram as in 3.4 to a diagram with coefficients in \([0, 1]\). First note that, for
our basis \((v_{i,j})_{i,j}\) and \((u_{i,j})_{i,j}\), we have \(\gamma_{i,j}^m = 0\) whenever \(j > \mu_m\) since \(u_m \in \ker(f^{m\ast})\). In particular, only columns of index less or equal than \(\mu_1\) may have non-zero tuples. The usual procedure will consider columns from right to left and, in each column, we will proceed from bottom to top. We prove the following proposition.

**Proposition 5.8.** With base changes of the forms 5.6 and 5.7 we can reduce the setup to a case where the labeled Young diagram satisfies the following conditions

1. If \(\mu = (3, 2)\), then there is an index \(i_0\) such that \(\gamma_{i_0,1} = (1,1)\). Otherwise, there might be one index \(i\), such that \(\gamma_{i,1} \neq 0\) and there exists at most one non-zero tuple \(\gamma_{i,j}\) with \(j \geq 2\).

2. Each tuple \(\gamma_{i,j}\) with \((i, j) \neq (i_0, 1)\) is either zero or of the form \(e_s\) for some \(s\), such that \(\mu_s \geq j\).

3. In each row \(i \neq i_0\), there exists at most one non-zero tuple \(\gamma_{i,j}\).

4. In each column \(j \neq 1\), for each \(s\), there is at most one \(\gamma_{i,s}\) equal to \(e_s\). For each \(s\) there exists at most one index \(i \neq i_0\), such that \(\gamma_{i,s} = e_s\).

At some point of the proof, we will meet some indices called \(i_0\) and \(i_0\). They should be seen as candidates to be the specific indices of the proposition. However, we will meet some cases where \(\gamma_{i_0,1} = e_s\) or \(\gamma_{i_0,1} = 0\). In these cases, the index should be discarded.

**Proof.** We distinguish three main cases, depending on \(\mu\).

a) \(\mu = (2^a, 1^{l-2a})\) for some \(a \in \mathbb{N}\).

b) \(\mu = (a, 1^{l-a})\) for some \(a \geq 3\).

c) \(\mu = (3, 2)\).

**Case a)\)** Set \(j := \mu_1 \in \{1, 2\}\).

First step of case a): We focus at first on column \(j\).

We initialize \(s\) to 0 and apply the following iterative procedure for decreasing \(i\) from \(\max\{i \mid i \geq j\}\) to 1. During each loop, no \(\gamma_{i,j}\) for \(i' > i\) is modified. After each loop, we will have \(\gamma_{i,j} \in \{0, e_s\}\) while \(\gamma_{i',j} = 0\) for any \(s' \leq s\) and \(i' < i\). In particular, we will never begin a loop with \(\gamma_{i,j} \in W_i \setminus \{0\}\).

Given \(i\), if \(\gamma_{i,j} \neq 0\), then \(\gamma_{i,j} \notin W_i\). So a base change of the form \(D_j\) sends \(\gamma_{i,j}\) to \(e_{s+1}\) and preserves \(e_1, \ldots, e_s\). Apply then a base change of the form \(C_{i,j}\) to bring any \(\gamma_{i',j'}\) to 0 for any \(i' \leq i, j' \leq j, (i', j') \neq (i, j)\). If \(j = 2\), apply also a base change of the form \(E_{i,1}\) to provide \(\gamma_{i,1} = 0\). Set \(i_{s+1} := i\) for later use and \(s \leftarrow s + 1\).

If \(\gamma_{i,j} = 0\), we do nothing.
We are thus left with a picture of the following form. Note that this gives the desired result when \( j = 1 \), that is when \( \mu = (1') \).

![Matrix Image]

Second step of case a): All that remains to be done is to reduce the first column in the case \( \mu_1 = 2 \). This will be achieved using base changes on \( U \) of the form \( D_j \) where the matrix \( A \) is in upper triangular form.

We initialize a variable subset \( S \subseteq [1, h] \) to \( \emptyset \) and we apply an iterative procedure for decreasing \( i = g, \ldots, 1 \). After each loop the above shape (6) is preserved and no \( \gamma_{i',1} \) is modified for \( i' > i \). Moreover, we will have \( \gamma_{i',1} = 0 \) for any \( i' < i \) and \( s \in S \). In particular, we will have \( \gamma_{i,1} \neq 0 \) for any \( s \in S \) at the beginning of every loop.

Given \( i \) such that \( \gamma_{i,1} \neq 0 \):

- We define \( s \in [1, h] \) via \( \gamma_{i,1} \notin W_s \ \text{\&} \ \gamma_{i,1} \in W_s-1 \).
- If \( s > a \) (resp. if \( s \leq a \)) then a base change of the form \( D_1 \) (resp. \( D_2 \)) brings \( \gamma_{i,1} \) to \( e_1 \), fixing each \( e_{s'} \) for \( s \neq s' \). Meanwhile, among the previously fixed tuples, only \( \gamma_{i,2} \) may have changed (if \( s \leq a \)), and the new tuple still lies in \( W_s \), since the matrix \( A \) in (5) of this particular base change is triangular. In this case, since \( i' > i \) for \( s' < s \), base changes of the form \( C_{i',2} \) (\( s' < s \)) and \( M_{i,2} \) allow to bring \( \gamma_{i,2} \) back to \( e_s \).
- Applying \( C_{i,1} \) allows then to set \( \gamma_{i',1} = 0 \) for any \( i' < i \).
- Set \( S \leftarrow S \cup \{ s \} \).

If \( \gamma_{i,1} = 0 \), we do nothing.

**Case b.** Set \( \mu_2 := 0 \) if \( h = 1 \), that is, if \( \mu = (\mu_1) \). We have \( \mu_1 > \mu_2 \) and the only non-zero coefficients \( \gamma_{i,j}^m \) with \( \mu_2 < j < \mu_1 \) arise when \( m = 1 \).

First step of case b): Iteratively for decreasing \( j = \mu_1, \ldots, \mu_2+1 \) we apply the following algorithm.

- Consider the lowermost non-zero tuple in column \( j \) (if it exists) and denote by \( i_j \) the index of its row.
- Apply a base change of the form \( M_{i,j} \) to bring \( \gamma_{i,j} \) to \( e_1 \).
- Apply a base change of the form \( C_{i,j} \) to kill the first entry of tuples in the quadrant northwest to \((i_j, j)\) to zero. In particular, \( \gamma_{i',j} = 0 \) when \( i' < i_j \).

Note that this gives Proposition 5.8 if \( h = 1 \).

From now on, let \( h \geq 2 \), that is, \( \mu_2 = 1 \). All that remains to be done is to modify the entries on the first column. Some difficulties arise when considering non-zero tuples...
\[ \gamma_{i,1} \text{ for some } 1 < j \leq \mu_1 - 1. \] Since \( l \leq 5 \), either \( h = 2 \), so all such non-zero tuples are colinear (multiples of \((0, 1)\)), or \( h \geq 3 \), so \( \mu_1 \leq 3 \). In the first case, base changes of the form \( B_{i_0,i_1}^{(j),(j')} \) for \( j > j' \) kill all \( \gamma_{j,1} \) but the lowermost non-zero one (if exists). In the second case, we can apply a base change of the form \( E_{1,i_0} \) to kill \( \gamma_{i_0,1} \). In this last case, the only possible remaining non-zero tuple \( \gamma_{i,1} \) arises for \( j = 2 \).

In a compatible way to Proposition 5.8, we define \( i_* := i_j \) where \( j \) is the index such that \( \gamma_{j,1} \neq 0 \), if exists. We are thus left with a picture of the following form.

\[
\begin{array}{cccccc}
(0,1) & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & (1,0) & 0 & 0 & 0 \\
0 & 0 & (1,0) & 0 & 0 & 0 \\
(0,1) & 0 & 0 & 0 & 0 & 0 \\
(0) & 0 & 0 & 0 & 0 & 0 \\
(+,0) & 0 & 0 & 0 & 0 & 0 \\
(+) & 0 & 0 & 0 & 0 & 0 \\
\end{array}
\]

\( i_5 
\]

\[ i_3 \]

\[ i_2 = i_* \]

\[ \mu_1 \]

Second step of case b):

We initialize \( S \) to \( \emptyset \) and we apply an iterative procedure for decreasing \( i = g, \ldots, 1 \). After each step the above shape (7) is preserved (with \( \mu_2 = 1 \)) and for each \( i' > i \), the tuple \( \gamma_{i',1} \in \{0\} \cup \{e_s \mid s \in S \cup \{2\}\} \) is preserved (up to a possible permutation of the coordinates when \( i = i_* \)). The only case with \( i' > i \), \( \gamma_{i',1} = e_2, 2 \notin S \) will arise when \( i' = i_* \). We will also have \( \gamma_{i',1} = 0 \) for any \( i' < i \) and any \( s \in S \). In particular, we will have \( \gamma_{i,1} \notin W_s \setminus W_{s-1} \) for every \( s \in S \) at the beginning of every loop.

Given \( i \), if \( \gamma_{i,1} \neq 0 \), we consider the following cases:

- Assume that \( (i > i_*) \) or \( (i < i_* \) and \( \gamma_{i,1} \notin K\gamma_{i_*},1) \) or \( (i_* \) does not exists).

Define \( s \) as the index such that \( \gamma \in W_s \setminus W_{s-1} \). We have \( s \in S \).

- If \( i = 1 \), apply \( M_i \) to bring \( \gamma_i,1 \) to \( e_1 \).
- If \( s \neq 1 \), a base change of the form \( D_i \) brings \( \gamma_i,1 \) to \( e_r \), thereby fixing each tuple in the picture which is given by \( e_r \) \( (s \neq s') \). Note that \( \gamma_{i,1} = 0 \) whenever \( i < i_* \) and \( \gamma_{i_*} = e_2 \), so \( s \neq 2 \) and \( \gamma_{i,1} \) is preserved.

Then apply a base change of the form \( C_{i,1} \) to kill each \( \gamma_{i,1}^{(i')} \) \( (i' < i) \).

Set \( S \leftarrow S \cup \{s\} \).

- If \( i = i_* \), then \( \gamma_{i,1} \in W_s \setminus W_{s-1} \) for some \( s \neq 1 \). A base change of the form \( D_i \) turns \( \gamma_{i,1} \) to \( e_r \), fixing each \( e_{r'} \) \( (s' \neq s) \).

Define the map \( \sigma : \{1, g\} \to \{1, g\} \) via \( \sigma(s) = 2, \sigma(s') = s' + 1 \) for \( 2 \leq s' < s \), and \( \sigma(s) = s \) otherwise. An additional base change of the form \( D_i \) sends each \( e_{r'} \) to \( e_{\sigma(r')} \). Set \( S \leftarrow \sigma(S) \), then.

- If \( i < i_* \), and \( \gamma_{i,1} \in K\gamma_{i_*},1 \), then a base change of the form \( M_i \) brings \( \gamma_{i,1} \) to \( e_2 \).

Apply \( C_{i,1} \) to kill each \( \gamma_{i,1}^{(i')} \) \( (i' < i) \), then. Set \( S \leftarrow S \cup \{2\} \).

If \( \gamma_{i,1} = 0 \), we do nothing.
Case c): $\mu = (3, 2)$.

First step of case c): Arguing as in case a) with $\mu = (2, 1)$, we can reduce columns 3 and 2. Then there exists a single index $i_3$ such that $\gamma_{i_3, 3} \neq 0$, and $\gamma_{i_3, 3} = (1, 0)$. There also exist at most 2 indices $i = i_2, i_s$, such that $\gamma_{i, 2} \neq 0$ and we obtain $\gamma_{i, 2} = (0, 1)$ and $\gamma_{i_s, 2} = (1, 0)$. Moreover, $i_3, i_2, i_s$ are distinct and $i_s > i_3$.

Next we apply $E_{1,1}$ and $E_{2,1}$ to kill $\gamma_{i_0, 1}$ and $\gamma_{i_s, 1}$. We also apply $C_{i_0, 3}$, and $C_{i, 1}$ (resp. $C_{i_0, 2}$) to set $\gamma_{i, 1}^3 = 0$ (resp. $\gamma_{i_0, 1}^3$) for $i \leq \max(i_3, i_s)$ (resp. $i \leq i_2$). The picture then looks as follows

\[
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & (0,1) & 0 & 0 \\
0 & 0 & (1,0) & i_3 \\
0 & 0 & 0 & i_3 \\
0 & 0 & (1,0) & i_s \\
0 & (0) & 0 & (0) \\
\end{array}
\]

Second step of case c): Consider now the lowermost non-zero tuple on the first column $\gamma_{i_0, 1}$. We will conclude using base changes on $U$ and $V$; however those base changes used on $U$ are always of the form

\[
u_1 \leftarrow \alpha u_1, \quad u_2 \leftarrow \beta u_2.
\]

- Assume that $\gamma_{i_0, 1} \notin Ke_1 \cup Ke_2$. Then $i_0 \notin \{i_3, i_2, i_s\}$ and $i_0 > i_s$ (otherwise $\gamma_{i_0, 1} = 0$).
  A base change of the form (8) followed by base changes of the form $M_{i_1}, M_{i_2}$, $M_i$ brings $\gamma_{i_0, 1}$ to $(1, 1)$ without modifying column 2 and 3.
  Apply a base change of the form $C_{i_0, 1}$ to kill any $\gamma_{i', 1}^3$ ($i' < i_0$) and note that the corresponding entries $\gamma_{i', 1}$ are changed, thereby. But, in particular if $i_s$ exists, the whole tuple $\gamma_{i_s, 1}$ is killed by an additional base change of the form $C_{i_s, 2}$.
  The next lowermost non-zero couple on the first column $\gamma_{i, 1}$ can then be brought to $(1, 0)$ by a base change $M_i$ and allows to kill any $\gamma_{i', 1}$ ($i' < i$) by a base change of the form $C_{i, 1}$.

- Assume that $\gamma_{i_0, 1} \in Ke_s$ for some $s \in \{1, 2\}$. We apply the following procedure for decreasing $i = i_0, \ldots, 1$. At the beginning of each loop $i$, we will have $\gamma_{i, 1} \in Ke_s$ for some $s \in \{1, 2\}$.
  Given $i$, assume that $\gamma_{i, 1} \neq 0$ (otherwise do nothing and go over to the next smaller $i$):
  - If $i \neq i_s$, then a base change of the form $M_i$ allows to set $\gamma_{i, 1}$ to $e_s$ for some $s \in \{1, 2\}$.

25
Apply then \( C_i \) to get \( \gamma_{i,1}^{s} = 0 \) \((i' < i)\). Note that this implies \( \gamma_{i,1}^{s' \ast} \in Ke_{s'} \) \((i' < i)\) where \( s' \) is the index, such that \( \{ s, s' \} = \{1, 2\} \).

- If \( i = i_* \), then \( \gamma_{i,1} \in Ke_2 \). A base change of the form (8) on \( u_2 \) followed by base change \( M_{b_i} \) yields \( \gamma_{i,1} = e_2 \) without modifying entries in column 2 and 3. \( \square \)

**Corollary 5.9.** The number of \( P \)-orbits in \( \mathcal{N}_b \) is finite if \( \mathbf{b}_P = (5, k) \) for some \( k \).

### 5.4 Main cases

Relying on the results of the previous subsection, we now indicate how to deduce finiteness in the four maximal cases of diagram (B.2).

**Proof of Lemma 5.2** Let \( \mathbf{b}_P = (5, k, 1) \). We consider quadruples of the form \((U, V, f, \varphi)\) with \((U, V, f)\) giving rise to a representation of \( \text{rep}^{s_1, s_2}(Q_2, I_n) \) of dimension \((5, k + 6)\) as in (1) and \( \varphi \in V^* \), such that \( U \subset \ker(\varphi) \) and \( \ker(\varphi) \) is \( f \)-stable. The corresponding representation of \( \text{rep}^{s_1, s_2}(Q_3, I_n) \) is

\[
\begin{array}{ccc}
\& f_{U} \& f_{\ker(\varphi)} \& f \\
\cap & \cap & \cap \\
U & \hookrightarrow & \ker(\varphi) & \hookrightarrow & V
\end{array}
\]

We consider these quadruples up to isomorphism, that is, up to an isomorphism of \( \text{rep}^{s_1, s_2}(Q_2, I_n) \) together with a scalar multiplication on \( \varphi \). Given such \((U, V, f, \varphi)\), we first consider the triple \((V, f, \varphi)\). It follows from a dual statement to [7, Lemma 5.3] that there exists a basis \((v_{i,j})_{i,j} \) of \( V \), such that \( f \) is in Jordan normal form in this basis and such that there exists \( i_* \) with \( \lambda_i < \lambda_{i_*} \) for any \( i > i_* \) and \( \varphi(v_{i,j}) = 0 \) unless \((i, j) = (i_*, \lambda_{i_*}) \).

We can carry out the whole reduction procedure of Section 5.3 applied to the pair \((U, V, f)\) while parallely considering how the applied base changes modify \( \varphi \). Within the used base changes on \( V \) of Tools 5.6 (namely \( M, C \) and \( B \)), only \( M_{b_i} \) can modify \( \varphi \) and this modification is just a scalar multiplication. In particular, \( \ker(\varphi) = \langle v_{i,j} \rangle_{(i,j) \in (1, \lambda_{i_*})} \) and there are at most \( \|\lambda_i | i \in [1, g]\| \) different isomorphism classes \((U, V, f, \varphi)\) for each isomorphism class \((U, V, f)\). Finiteness follows for the case \( \mathbf{b}_P = (5, k, 1) \).

We will now consider the cases \( \mathbf{b}_P \in \{(1, 3, k), (3, 1, k), (1, 1, 1, k)\} \). For these, we will reduce to a finite number of isomorphism classes, applying base changes on \( U \) and on \( V \), such that every base changes on \( V \) is one of the three tools 5.6.

Let us consider the case \( \mathbf{b}_P = (1, l, k) \), \( l \leq 3 \). It amounts to classify quadruples \((u', U, V, f)\) with \((U, V, f)\) as in previous subsections, \( \dim U = l + 1 \), \( \dim V = k + l + 1 \) and \( u' \in U \cap \ker f \). The quadruples should be considered up to isomorphism which is given in the corresponding representation context and arises by base changes on \( U \) and scalar multiplication on \( u' \). Using the notation introduced in 5.1 we distinguish 2 cases: either a) \( \mu_1 \leq 2 \) or b) \( \mu \in \{(4), (3), (3, 1)\} \).

26
• In case a), we carry out the reductions of Section 5.3 on \((U, V, f)\) in order to get a labeled Young diagram as in Proposition 5.8. Then, writing \(u' = \sum \eta_m u_{m,1}\), we proceed to the following base change on \(U\)

\[
u_m \leftarrow \eta_m u_m \text{ for each } m, \text{ such that } \eta_m \neq 0.
\]

Meanwhile, in the labeled Young diagram, each \(e_m\) has been changed to \(\eta_m e_m\).

Since for each row \(i\), there is at most one box \((i, j)\), such that \(\gamma_{i,j} \neq 0\), base changes on \(V\) of the form \(M_t\) allow to recover the original labeled Young diagram.

We, thus, have our finiteness result: each situation can be reduced to a case where \((U, V, f)\) fulfills the conditions of Proposition 5.8 and \(u' = \sum e_m u_m\) with \(e_m \in \{0, 1\}\) for all \(m\).

• In case b), we first assume that \(u' \in f^{m-1}(U)\). This way, no infinite family can arise, since \(\dim f^{m-1}(U) = 1\) in all provided cases.

The only remaining case to consider is \(\mu = (3, 1)\) and \(u' \notin f^{2}(U)\). Choosing \(u_1 \in \ker f^2, u_{1,j} := f^{3-i}(u_1)\) and \(u_2 := u'\), a basis of \(U\) arises in which \(f\) is in Jordan normal form. It is then possible to carry out the reductions of Section 5.3 using as base changes on \(U\) only those of the form \(E\) (and accordingly \(u' \leftarrow \beta u'\)). Indeed, the second and third column of the labeled Young diagram can be treated as in the first step of case b) of Section 5.3, without the use of base change \(E_{1,j}\). The first column can then be reduced as in the second step of case c) of Section 5.3.

The case \((l, 1, k)\) \((l \leq 3)\) amounts to classify quadruples \((\varphi, U, V, f)\) with \((U, V, f)\) as in previous subsections, \(\dim U = l + 1, \dim V = k + l + 1\) and \(\varphi \in U^*\), such that \(\ker(\varphi)\) is \(f\)-stable. The isomorphisms are given by base changes on \(U, V\) and scalar multiplication on \(\varphi\). Since \(f\) is nilpotent and \(\dim_{\varphi} U/\ker \varphi = 1\), we know that \(f(U) \subset \ker(\varphi)\) and given a basis \((u_{m,l})_{m,l}\) in which \(f\) is in Jordan normal form, \(\varphi\) is completely determined by \((\varphi(u_m))_{m}\).

We can then proceed as in the \((1, l, k)\)-case. Namely, in case a) we argue in the same way, with base changes on \(U\) given by \(u_m \leftarrow (\varphi(u_m))^{-1} u_m\); here \(u_m := u_{m,l}\).

In case b), the generic cases happen with \(\mu = (3, 1)\) and \(\ker(\varphi) \neq \ker(f(U)^2)\). In this situation, we choose \(u_1 \in \ker(\varphi) \setminus \ker(f(U)^2)\) and obtain \(\ker(\varphi) = Ku_1 \oplus Kf(u_1) \oplus Kf^2(u_1)\). Choose \(u_2 \in \ker(f) \setminus Kf^2(u_1)\) in order to get a basis in which \(f\) is in Jordan normal form. Then the same arguments as in the \((1, 3, k)\)-case apply.

The last case to consider is \(b_{3,n} := (1, 1, 1, k)\). It amounts to classify quintuples \((U'', U', U, V, f)\) with \((U, V, f)\) as in previous subsections, \(U'' \subset U' \subset U\) all \(f\)-stable and \((\dim U'', \dim U, \dim U, \dim V) = (1, 2, 3, k + 3)\). We have 3 cases to consider:

• If \(\mu = (3)\), by Proposition 5.8 we can reduce to a finite number of choices for \((U, V, f)\). Then \(U'' = Ku_{1,1}\) and \(U' = U'' \oplus Ku_{1,2}\) follow without a choice and, thus, finiteness.

• Assume that \(\mu = (2, 1)\).

• If \(U' = \ker f(U)\), the finiteness follows from the classification of quadruples \((U'', U, V, f)\) which has been achieved in the case \(b_{3,n} = (1, 2, k)\).
– If \( U' \neq \ker f_{|U} \), then \( f(U') \) is its only \( f \)-stable subspace of dimension 1. So \( U'' = f(U') = f(U) \) and finiteness follows from the classification of quadruples \((U', U, V, f)\) which has been achieved in the case \( b_P = (2, 1, k) \).

- Assume that \( \mu = (1, 1, 1) \). Choose a basis \((u_1, u_2, u_3)\) of \( U \), such that \( U'' = Ku_3 \), \( U' = Ku_3 \oplus Ku_2 \). Without modifying these spaces, we can apply base changes of the form

\[
\begin{align*}
u_1 &\leftarrow \omega_1^1 u_1 + \omega_1^2 u_2 + \omega_1^3 u_3, \\
u_2 &\leftarrow \omega_2^1 u_2 + \omega_2^3 u_3, \\
u_3 &\leftarrow \omega_3^3 u_3.
\end{align*}
\]

as introduced in Subsection 5.2. The reduction of the first column of the labeled Young diagram can then be achieved as in the second step of case a) of Section 5.3 (with \( p = 0 \)).

We have shown finiteness for \( b_P \in \{(1, l, k), (l, 1, k), (1, 1, 1, k) \mid l \leq 3, k \in \mathbb{N}\} \). Enlarging these tuples \( b_P \) by an extra 1 on the right means that we have to add an extra data \( \varphi \in V^* \) to the considered representations of \( \text{rep}_{10}(Q_p, I_n) \) as explained in case \((5, k, 1)\). These cases can be dealt with in the very same way as above, where we deduced the \((5, k, 1)\)-case from the \((5, k)\)-case. □

6 Applications to Hilbert schemes and commuting varieties

In this section, we assume for simplicity that \( K \) is algebraically closed of characteristic zero.

A motivation to consider the classification of nilpotent \( P \)-orbits in \( \mathfrak{p} \) comes up in the context of commuting varieties and nested punctual Hilbert schemes [7].

Consider the nilpotent commuting variety of \( \mathfrak{p} \)

\[
C(N_p) := \{(x, y) \in N_p \times N_p \mid [x, y] = 0\},
\]

an important subvariety of the commuting variety \( C(\mathfrak{p}) := \{(x, y) \in \mathfrak{p} \times \mathfrak{p} \mid [x, y] = 0\} \) of \( \mathfrak{p} \). We refer to [22, 21], (resp. [19, 14], resp. [13, 7]) for ground results on commuting varieties and nilpotent commuting varieties of semisimple algebras (resp. Borel subalgebras, resp. parabolic subalgebras).

Clearly, \( P \) acts diagonally via conjugation on both varieties. For \( x \in N_p \), we define \( \mathfrak{p}^x = \{y \in \mathfrak{p} \mid [x, y] = 0\} \) and say that \( x \) is distinguished if \( \mathfrak{p}^x \cap \mathfrak{sl}_p \subset N_p \). A \( P \)-orbit in \( N_p \) is said to be distinguished, if all of its elements are distinguished.

**Proposition 6.1.**

1. If \( P \) acts finitely on \( N_p \), then \( \dim C(N_p) = \dim \mathfrak{p} - 1 \). Moreover, the irreducible components of maximal dimension are in one-to-one correspondence with the distinguished orbits in \( N_p \).

2. If there are infinitely many distinguished \( P \)-orbits in \( N_p \), then \( \dim C(N_p) \geq \dim \mathfrak{p} \).
Proof. We begin by proving 1 and assume that the number of $P$-orbits in $N_\rho$ is finite. Then we can decompose $C(N_\rho)$ into finitely many disjoint subsets as follows:

$$C(N_\rho) = \bigcup_{x \in N_\rho} P(x, p^x \cap N_\rho)$$

(9)

It follows from [7, (14)], that $\dim P(x, p^x \cap N_\rho) = \dim p - \codim_{p^x}(p^x \cap N_\rho)$. Since $p^x = K \cdot \text{id}(p^x \cap N_\rho)$, we see that $\codim_{p^x}(p^x \cap N_\rho) \geq 1$ with equality if and only if $x$ is distinguished. In this case, $P(x, p^x \cap N_\rho) = P(x, p^x \cap s_l)$ is irreducible. We still have to see that distinguished elements exist. An example is given by the regular nilpotent element in Jordan normal form.

We show 2 and assume that there are infinitely many distinguished $P$-orbits in $N_\rho$. It follows from (9) that $C(N_\rho)$ contains an infinite union of $(\dim p - 1)$-dimensional disjoint constructible subvarieties. The result follows. 

□

**Lemma 6.2.** Let $x \in N_\rho$ and $M$ be a corresponding representation of $\text{rep}^{\text{inj}}(Q_p, I_p)(d_\rho)$. Then $x$ is distinguished if and only if $M$ is indecomposable.

Proof. If $x$ is not distinguished then $x$ commutes with a semisimple element $s \in s_l \cap p$. Up to $P$-conjugacy, we can assume that $s$ is a diagonal matrix with entries $\alpha_1, \ldots, \alpha_n$. Denote by $\beta_1, \ldots, \beta_l$ (l $\geq 2$) the distinct eigenvalues of $s$ and by $J_i := \{ j \mid \alpha_j = \beta_i \}$ for each $i \in [1, l]$.

Let $gl_p$ be the set of matrices $A \in gl_p$, such that $Ae_j \in \langle \epsilon_k \mid k \in J_i \rangle$ if $j \in J_i$ and $Ae_j = 0$, otherwise. This means that $\bigoplus_i gl_p$ is (up to reordering of the $\epsilon_k$) a block-diagonal $gl$ subalgebra of $gl_p$ which equals the centralizer of $s$.

Then we can decompose $x = \sum_{i=1}^n x_i$ with $x_i \in gl_p \cap p$. Note that $gl_p \cap p$ is a parabolic subalgebra of $gl_p$.

Given, $i, j$, define $d_i^j := \#(J_i \cap [1, \ldots, d_j])$ and $d_i := (d_1^i, \ldots, d_n^i)$. Then, $M \cong \bigoplus M_i$ where $M_i$ is a representation of $\text{rep}^{\text{inj}}(Q_p, I_n)$ corresponding to $x_i$.

Assume now that we have a decomposition into non-trivial summands $M = M_1 \oplus M_2$. Denote by $d_i$ and $d_2$ the respective dimension vectors of $M_1$ and $M_2$. Then we can reason backwards and split $[1, n]$ into $J_1, J_2$ via $J_1 := \bigcup [d_i, d_i + d_2, -1, 1, d_i + d_2]$ and $J_2 := \bigcup [d_i, d_i + d_2, +1, 1, d_i + d_2]$, setting $d_0 := 0$. Then, we can assume that $x = x_1 + x_2$ with $x_i \in gl_p$ so $x$ commutes with the diagonal matrix of $s_l$, whose diagonal entries $\alpha_1, \ldots, \alpha_n$ are defined via $\alpha_j := 1/\sum_{i} d_i^j$ (resp. $\alpha_j := -1/\sum_{i} d_i^j$ if $j \in J_1$ (resp. $j \in J_2$).

□

As a consequence, we see that in the critical cases of Proposition 4.3, namely $b_\rho \in \{(6, 6), (2, 2, 2), (4, 1, 4), (1, 4, 6), (1, 2, 1, 4), (1, 2, 2, 1), (1, 2, 2, 1)\}$, we always have a one-parameter family of indecomposables of $\text{rep}^{\text{inj}}(Q_p, I_p)$ and hence of $\text{rep}^{\text{inj}}(Q_p, I_\rho)$. So $\dim C(N_\rho) \geq \dim p$ holds true in these cases. It is unclear whether this last property holds whenever $P$ acts on $N_\rho$ with infinitely many orbits (e.g. if $b_\rho = (2, 3, 2)$). However, it is sometimes easy to extend the indecomposables of Figures 1 and 2 to indecomposables with greater dimension. For instance, Figure 3 provides an indecomposable in the case $b_\rho = (k, k')$ with $k, k' \geq 6$. We can therefore state
Proposition 6.3. If $P$ is a maximal parabolic, then $\dim C(N_p) = \dim p - 1$ if and only if one of the blocks of $p$ is of size at most 5. Otherwise, $\dim C(N_p) \geq \dim p$.

In correspondence with these commuting varieties, one can study the so-called nested punctual Hilbert schemes. These Hilbert schemes were introduced in [8]. We refer to [7, Definition 3.7] for a scheme-theoretic definition. Such scheme depends on a non-decreasing sequence $d = (d_1, \ldots, d_p)$ and we will focus on Hilbert schemes on the plane $\mathbb{A}^2$ which we denote by $\text{Hilb}^{[d]}_0(\mathbb{A}^2)$. We recall that, set-theoretically,

$$\text{Hilb}^{[d]}_0(\mathbb{A}^2) = \{z_1 \subset z_2 \subset \cdots \subset z_p | z_i \text{ is a subscheme of } \mathbb{A}^2 \text{ of length } d_i\}.$$ 

Equivalently, we can consider $\text{Hilb}^{[d]}_0(\mathbb{A}^2)$ as the set of sequences of inclusions $I_1 \supset \cdots \supset I_p$ with $I_i$ an ideal of codimension $d_i$ in $K[X, Y]$.

Let us consider the open subvariety $C_{\text{cyc}}(N_p) = \{(x, y) \in C(N_p) | \exists v \in K^n \text{ s.t. } \langle x^iy^j, v \rangle_{i,j} = K^n\}$, of $C(N_p)$ now, that is, the set of couples admitting a cyclic vector. We will use the following result of [7, Proposition 3.13]. Recall that given $P$, denote the block sizes of $p$ by $b_P = (b_1, \ldots, b_p)$ and that we define $d_P = (d_1, \ldots, d_p)$ with $d_i = \sum_{j \leq i} b_j$.

Proposition 6.4. There is a one-to-one correspondence between the irreducible components of $C_{\text{cyc}}(N_p)$ of dimension $m + \dim p - n$ and the irreducible components of $\text{Hilb}^{[d]}_0(\mathbb{A}^2)$ of dimension $m$, where $d_{\overline{\nu}} := (n - d_{p-1}, \ldots, n - d_1, n)$.

A deeper connection between related schemes is expressed in [7, Proposition 3.2]. Let us mention that there always exists a component of $\text{Hilb}^{[d]}_0(\mathbb{A}^2)$ of dimension $n - 1$, the so-called curvilinear component. Proposition 6.4 is used in [7, Theorem 7.5]show
Remark 6.6. In the first case of the previous theorem, the same proof together with Lemma 6.2 yields a more precise result. Namely, the irreducible components of $\text{Hilb}^{[n]}(\mathbb{A}^2)$
of maximal dimension are in one-to-one correspondence with distinguished orbits \( P.x \in \mathcal{N}_p \) satisfying the following property:

\[ \exists y \in \mathcal{N}_p \cap \mathfrak{p}^s \text{ such that } (t_x, t_y) \text{ admits a cyclic vector.} \]

**Remark 6.7.** Since any prime is good for \( \text{GL}_n \), it is plausible that the results of this section remain true when \( K \) is algebraically closed of any characteristic. In particular, note that [7] considers fields of any characteristic. In positive characteristic, one should be careful when defining a distinguished nilpotent element. One can find clues about how to proceed in positive characteristic in [21, Section 3].

In the study of the irreducibility of the (non-nilpotent) commuting varieties \( C(p) \), it is crucial to estimate the modality of the action of the group on the cone of nilpotent elements, see e.g. the recent paper [13, Theorem 1.1]. The known examples of reducible commuting variety [13, Theorem 1.3 and Section 8] have at least 15 blocks and arise from the study of the modality of the action of \( P \) on \( \mathfrak{n}_p \). In particular, no example can arise with such method if \( P \) has less than 6 blocks.

The approach of the present paper might help to find examples of parabolics \( P \) with few blocks and a big modality on \( \mathcal{N}_p \). Indeed, using ordinary quiver theory, it is possible to find families of representations with a great number of parameters in \( \text{rep}^{\text{par}}(\widehat{Q}_p, \widehat{I}_n) \). For instance, if \( d = (d_{i,j})_{i,j} \) is such that \( R_d^{\text{par}}(\widehat{Q}_p, \widehat{I}_n) \neq \emptyset \) and the irreducible components of \( R_d(\widehat{Q}_p, \widehat{I}_n) \) are all of dimension at least \( m + \dim \text{GL}_d \) with \( m \geq 0 \), then there exists a \( m + 1 \)-parameter family in \( R_d^{\text{par}}(\widehat{Q}_p, \widehat{I}_n) \). This family translates to a \( m + 1 \)-parameter family of \( C(p, I_n) \) via Proposition 4.1 and, for the corresponding parabolic \( p \), the modality of \( \mathcal{N}_p \) is at least \( m + 1 \).

As an example, consider the following dimension vector in \( \widehat{Q}_2 \) and \( \widehat{Q}_5 \):

\[
\begin{array}{cccccc}
0 & 20 & 0 & 0 & 0 & 1 \\
0 & 40 & 0 & 0 & 0 & 2 \\
0 & 60 & 0 & 0 & 1 & 4 \\
20 & 80 & 0 & 1 & 4 & 7 \\
60 & 80 & 3 & 9 & 12 & 12 \\
60 & 60 & 3 & 6 & 7 & 7 \\
40 & 40 & 3 & 4 & 4 & 4 \\
20 & 20 & 2 & 2 & 2 & 2 \\
\end{array}
\begin{array}{cccccc}
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
\end{array}
\]

Here, \((m+1, n-1)\) is equal to \((401, 399)\) in the first case and \((64, 61)\) in the second case. Then, it follows from [13] that the corresponding parabolic subalgebras \( p \) of block sizes \( \mathfrak{p}_p = (200, 400) \) or \((11, 13, 14, 13, 11)\) have a reducible commuting variety \( C(p) \).
