IgA nephropathy (IgAN) is a common cause of renal failure worldwide. Treatment is limited because of a complex pathogenesis, including unknown factors favoring IgA1 deposition in the glomerular mesangium. IgA receptor abnormalities are implicated, including circulating IgA–soluble CD89 (sCD89) complexes and overexpression of the mesangial IgA1 receptor, TFR1 (transferrin receptor 1). Herein, we show that although mice expressing both human IgA1 and CD89 displayed circulating and mesangial deposits of IgA1–sCD89 complexes resulting in kidney inflammation, hematuria, and proteinuria, mice expressing IgA1 only displayed endocapillary IgA1 deposition but neither mesangial injury nor kidney dysfunction. sCD89 injection into IgA1-expressing mouse recipients induced mesangial IgA1 deposits. sCD89 was also detected in patient and mouse mesangium. IgA1 deposition involved a direct binding of sCD89 to mesangial TFR1 resulting in TFR1 up-regulation. sCD89–TFR1 interaction induced mesangial surface expression of TGase2 (transglutaminase 2), which in turn up-regulated TFR1 expression. In the absence of TGase2, IgA1–sCD89 deposits were dramatically impaired. These data reveal a cooperation between IgA1, sCD89, TFR1, and TGase2 on mesangial cells needed for disease development. They demonstrate that TGase2 is responsible for a pathogenic amplification loop facilitating IgA1–sCD89 deposition and mesangial cell activation, thus identifying TGase2 as a target for therapeutic intervention in this disease.

Transglutaminase is essential for IgA nephropathy development acting through IgA receptors

IgA nephropathy (IgAN), a major cause of end-stage renal disease (Donadio and Grande, 2002), affects both native and transplanted kidneys with recurrence after transplantation occurring in about one third of patients (Berger et al., 1975; Ponticelli and Glassock, 2010). Mesangial IgA deposits, mainly characterized as of the IgA1 subclass, appear as the first step of the disease together with circulating immune complexes containing IgA1 with abnormal O-linked glycosylation (Monteiro et al., 1985; Tomana et al., 1999; Novak et al., 2008; Tissandie et al., 2011). IgAs are unique immunoglobulins with exceptional heterogeneity. In addition to secreted and serum forms, they exist as two subclasses (IgA1 and IgA2) and are present in the circulation as monomers and polymers that are covalently associated by...
the joining (J) chain. In healthy individuals (contrary to other species like the mouse), circulating IgAs are essentially monomeric. IgA receptors (IgARs) have been proposed to play a role in IgAN pathogenesis (Monteiro et al., 2002). Within the family of multiple IgARs, the myeloid FcαRI (CD89) and TfR1 (transferrin receptor 1; CD71) were identified as putative pathogenic factors in IgAN patients with altered expression on monocytes (Grossêtète et al., 1998) and mesangial cells (Moura et al., 2001), respectively. Although CD89 shedding from myeloid cells results in pathogenic soluble forms complexed to IgA (Launay et al., 2000), TfR1 is overexpressed on mesangial cells after IgA1 complex deposition (Haddad et al., 2003). Deposits of IgA1 immune complexes in the mesangium could thus be formed through interaction of these complexes with the mesangial TfR1, but this could not be experimentally demonstrated in vivo because of the lack of a valid animal model reproducing the human IgA1 system. Previously, we have shown that transgenic (Tg) mice expressing the human CD89 on monocytes/macrophages display mouse IgA–human CD89 interaction on these cells and spontaneously develop mouse IgA deposits in their mesangium at 24 wk (Launay et al., 2000). However, it has been claimed that mouse IgAs fail to bind to human CD89 in vitro (Pless et al., 1999) and that injection of soluble CD89 (sCD89) does not induce mouse IgA deposition in the mesangium (van der Boog et al., 2004). The role of mouse IgA–human sCD89 complexes in IgAN development in CD89Tg mice was indirectly demonstrated by serum transfer experiments from CD89Tg into WT mice induced TfR1 overexpression and IgA1 mesangial deposits, whereas CD89Tg mice developed early mesangial IgA1 deposits with hematuria and overt proteinuria.

RESULTS

Mice expressing human IgA1 and CD89 developed early mesangial IgA1 deposits with hematuria and overt proteinuria.

The IgA system differs between humans and mice (Kerr, 1990). Although humans display two IgA subclasses and a myeloid IgAR belonging to the Fc receptor family, the CD89 (or FcαRI), mice have only one IgA subclass differing from the human counterpart by its shorter hinge region (where O-glycosylation occurs) and lack a CD89 homologue (Monteiro and Van De Winkel, 2003). Therefore, to establish a model that mimics human IgAN, we backcrossed CD89Tg mice with α1KI mice, which produce significant amounts of human IgA1 in the circulation (0.5–1 mg/ml; Duchez et al., 2010). Although both α1KI and α1KI-CD89Tg mice presented glomerular deposits of IgA1 at 12 wk of age, α1KI-CD89Tg mice displayed typical mesangial IgA1 deposits, whereas α1KI mice exhibited diffuse endocapillary deposits of IgA1 (Fig. 1 A). The latter was demonstrated by confocal immunofluorescence analysis showing extensive colocalization of the vascular marker CD31 with IgA1 deposits within the capillary walls of α1KI but not α1KI-CD89Tg mice (Fig. 1 A). Moreover, dense materials were observed in the mesangial area for α1KI-CD89Tg mice and in the endocapillary area for α1KI mice using transmission electron microscopy (Fig. 1 B). Mesangial IgA1 deposits started at 6 wk of age in α1KI-CD89Tg mice with an intense pattern detected starting at 12 wk (Fig. 1 C). This contrasted with the late detection of mouse IgA staining observed in 24-wk-old CD89Tg mice in similar 129-C57BL/6 background, confirming our previous observations in NOD.C57BL/6 CD89Tg mice (not depicted; Launay et al., 2000). To address whether these differences in IgA1 deposition kinetics resulted from affinity differences between mouse and human IgA to CD89, we performed surface plasmon resonance experiments using recombinant sCD89. Mouse IgA interacted with sCD89 with a very low affinity (Kd ~7.6 × 10^-5 M; Fig. 1 D), which was 100 times lower than that of human IgA1 and of monoclonal human IgA1 obtained from α1KI mice (Fig. 1 E). Moreover, morphological analyses of α1KI-CD89Tg kidneys showed expansion of mesangial extra cellular matrix as indicated by periodic acid Schiff (PAS) staining (Fig. 1 F), which was also accompanied by fibronectin overexpression (Fig. 1 A).

α1KI-CD89Tg mice exhibited marked MBL and C3 glomerular deposits, hallmarks of IgAN, whereas in α1KI and WT mice, these deposits were notably less intense (Fig. 2 A). As anti-IgA1 IgG have been reported in patients (Suzuki et al., 2009),
was significantly observed in glomeruli and periglomerular interstitial areas of α1KI-CD89Tg mice, indicating that a local inflammation occurs in kidneys of these mice that express human CD89. α1KI-CD89Tg mice also presented features of altered kidney function such as proteinuria, albuminuria, hematuria, and increase in serum creatinine levels (Fig. 2, C–G). Proteinuria started at 12 wk and was more intense at 24 wk (Fig. 2 D). Although no significant proteinuria was found in α1KI mice, CD89Tg mice in the 129-C57BL/6 background displayed very mild proteinuria (not depicted) as previously described (Launay et al., 2000). However, proteinuria was completely abolished in NOD.SCID-CD89Tg mice that lack IgA (not depicted). Collectively, these results show that the presence of both human IgA1 and CD89 promotes increased mesangial IgA1 deposition, hematuria and proteinuria, and altered renal function in mice.

sCD89 induces high molecular mass circulating IgA1 complexes and mediates mesangial IgA1 deposition

As α1KI-CD89Tg mice developed pathogenic mesangial IgA1 deposits, we next investigated whether circulating sCD89 was complexed with IgA1. Cell surface expression of CD89 on blood monocytes, absent in α1KI and WT mice, was lower in α1KI-CD89Tg than in CD89Tg mice (Fig. 3 A), suggesting that expression of human IgA1 in mice may enhance shedding of CD89 as previously shown in vitro (Launay et al., 2000). Similar results

Figure 1. CD89 determines mesangial deposition of IgA1. (A) From left to right: immunostaining for human IgA1 in frozen kidney sections, double immunofluorescence for human IgA1 and CD31, PAS staining of paraffin-embedded kidney sections, and immunofluorescent staining for fibronectin in frozen sections from α1KI-CD89Tg versus α1KI and WT mice (12 wk old). Arrows indicate colocalization of IgA1 and CD31. (B) Transmission electron microscopy pictomicrographs of glomeruli from α1KI-CD89Tg versus α1KI and WT mice (12 wk old). C, capillary; E, endothelial cell; M, mesangial cell; P, podocyte. Arrows indicate dense materials. (C) Immunostaining for human IgA1 in frozen kidney sections of 6- and 24-wk-old α1KI-CD89Tg mice. Bars: [A and C] 10 µm; [B] 2 µm. (D) Dose-dependent interaction of mouse IgA with sCD89 monitored by real-time surface plasmon resonance (SPR). (E) Association of different types of IgA (mouse IgA, α1KI mouse IgA1, and human IgA1; 5 µM) with sCD89.
The presence of sCD89 was further demonstrated in fractions containing high molecular mass IgA1 complexes by immunoprecipitation assays using anti-sCD89 mAb A3 coupled to beads followed by SDS-PAGE at nonreducing conditions and Western blotting using a cocktail of anti-sCD89 mAbs (Fig. 3 H). A 50–70-kD sCD89 protein was detected under reducing conditions overlapping the α chain (not depicted) as previously described (Launay et al., 2000).

We next assessed the presence of CD89 in the mesangium by using an anti-sCD89 polyclonal antibody. α1KI-CD89Tg kidney sections displayed positive stainings for CD89 with a typical mesangial pattern (Fig. 4 A). We then addressed whether anti-sCD89 polyclonal antibody stained CD89 on biopsies from IgAN patients. As shown in Fig. 4 B, a mesangial pattern of CD89 staining was observed that was abolished in the presence of an excess of sCD89. This staining was confirmed in biopsies from two additional IgAN patients but not in biopsies from patients with minimal change disease (not depicted). To formally demonstrate that sCD89 is responsible for mesangial IgA1 deposition, we injected recombinant sCD89 into 6-wk-old α1KI mice because they display very few deposits of IgA1 in their glomerular capillary walls. sCD89 induced massive mesangial IgA1 deposits when compared with mice that received an irrelevant control protein BSA (Fig. 4 C).

Figure 2. CD89 is required for complement deposition, leukocyte infiltration, proteinuria, and hematuria. To further determine the nature of CD89 (soluble or transmembrane form ectopically expressed on infiltrating cells) deposited in mesangial areas of α1KI-CD89Tg mice, saline-perfused kidneys were subjected to acid elution procedures as described previously (Monteiro et al., 1985). After neutralization, IgA1–sCD89 complexes were detected by ELISA in eluates from α1KI-CD89Tg mice but not in those from α1KI mice (Fig. 4 D). More importantly, size exclusion resolution of kidney eluates revealed that high molecular mass IgA1 complexes (>670 kD) represented the predominant form (56%) of IgA1 present in mesangial deposits of α1KI-CD89Tg mice (Fig. 4 E), confirming data previously observed in IgAN patients and further demonstrating that macromolecular IgA is the main IgA form trapped in mesangial areas (Monteiro et al., 1985). As observed previously with CD89Tg mice (Launay et al., 2000), the ability of IgA1–sCD89 complexes to transfer the disease was demonstrated in NOD.SCID mice that developed IgA1 mesangial deposits and hematuria 24 h after injection of serum from α1KI-CD89Tg mice (not depicted). Together, α1KI-CD89Tg mice data indicated that circulating high molecular mass IgA1–sCD89 complexes are responsible for mesangial IgA1 deposition in IgAN.

sCD89 binds to TR1 and induces its overexpression on mesangial cells

TR1 is an IgA1 receptor that is overexpressed in the mesangium of patients with IgAN (Moura et al., 2001; Haddad et al., 2003) and enterocytes from patients with celiac disease (Matysiak-Budnik et al., 2008). As human IgA1 interacts with mouse TR1 (Coulon et al., 2011), we next examined whether knockin expression of human IgA1 in the mouse could induce mesangial TR1 expression and whether this overexpression was dependent on CD89. Although α1KI mice displayed a slight increase in TR1+ cells in their mesangium, the presence of CD89 markedly enhanced (more than threefold) the TR1 expression in the mesangium of α1KI-CD89Tg mice (Fig. 5 A). CD89-mediated overexpression of TR1 increased with age.

we investigated whether tissue mesangial cells express a protein associated to TIR1 that may control the expression of TIR1 and therefore favor IgA1 binding. Because TGase2, a cross-linking enzyme with pleiotropic functions (Lorand and Graham, 2003), is overexpressed in the mesangium of IgAN patients and correlated with renal function decline (Ikee et al., 2007), we examined whether it could modulate IgA1 complex deposition and TIR1 expression. TGase2 expression was markedly up-regulated in the mesangium of α1KI-CD89Tg mice, whereas it was only weakly detected in α1KI and absent in WT mice (Fig. 7 A), indicating a role of sCD89 in its regulation. Mesangial TGase2 overexpression was confirmed in biopsies of IgAN patients (Fig. 7 B), as reported by others (Ikee et al., 2007). This was also supported by experiments in which injection of recombinant sCD89 in α1KI mice resulted in increased TGase2 staining (Fig. 7 C). Recombinant sCD89 but not IgA1 also up-regulated TGase2 expression on the surface of HMCs (approximately threefold increase; Fig. 7 D). However, IgA1 strongly bound to TGase2 in an antibody-independent manner because normal human serum IgA as well as antiovalbumin IgA1 mAb obtained from hybridoma derived from α1KI mice equally bound to TGase2 (Fig. 8 A) and not mouse IgG (not depicted). Confocal analysis of kidney sections revealed that TGase2 was strongly colocalized with mesangial IgA1 deposits in α1KI-CD89Tg mice but not in

**Figure 5.** sCD89 interacts with TIR1 and induces up-regulation of its expression on mesangial cells. (A–C) Frozen kidney sections immunostained for mouse TIR1 from 12-wk-old WT, α1KI, and α1KI-CD89Tg mice (A), 6-wk-old α1KI mice injected i.v. with BSA or sCD89 (B), and NOD.SCID mice injected with BSA or sCD89 (C). Arrows indicate TIR1+ cells. The corresponding graphs represent the numbers of positive cells per glomerulus counted in 20 randomly chosen fields for each mouse at 200 magnification. n = 3 mice per group. Bars: [A] 10 µm; [B and C] 5 µm. (D) Flow cytometry histogram (one representative experiment of six) of HMCs binding sCD89 (white layer) and stained with anti-TIR1. Transglutaminase is crucial for IgA nephropathy | Berthelot et al.

was observed when ELISA plates coated with recombinant sTIR1 were preincubated with TGase2 (Fig. 9 A), suggesting that similar to sCD89, TGase2 may be involved in the binding and stabilization of mesangial IgA1 deposits. This was confirmed on HMCs where binding of IgA1 was increased when cells were preincubated with TGase2 (Fig. 9 B). To evaluate the involvement of TGase2 in IgA1 deposition formation in IgAN, TGase2-deficient mice were backcrossed with α1KI-CD89Tg mice, and the development of IgAN was assessed. Immunohistochemistry analysis showed that IgA1 deposits were almost abolished in the mesangium of α1KI-CD89Tg-TGase2−/− mice (Fig. 9 C). Mesangial expression of TIR1 was also markedly reduced in these mice together with a decrease in MBL and C3 deposits and in macrophage infiltration (Fig. 9 D). Hematuria was abolished to the spontaneous level observed in WT animals (Fig. 9 E), which was associated with a slight decrease in proteinuria and serum creatinine levels although not reaching statistical significance (not depicted). These results indicate that sCD89 up-regulates TGase2 expression on mesangial cells and that TGase2 binds to TIR1 and IgA1 independently of a given antibody activity enhancing the formation of mesangial IgA1 deposits and the triggering of an overt IgAN.

**DISCUSSION**

The present study identifies new players, molecular connections, and sequences of events involved in the development of IgAN. Our data demonstrate that besides IgA1, TIR1 can also

α1KI mice (Fig. 8 B). Moreover, only α1KI-CD89Tg mice exhibited stronger colocalization in their mesangium between fibronectin and TGase2 molecules or IgA1 deposits than α1KI mice (Fig. 8, C and D), suggesting that TGase2 both controls mesangial IgA1 deposition and could contribute to the mesangial extracellular matrix expansion observed in IgAN. As TGase2 is known to be tightly involved in the stabilization of extracellular matrix (Lorand and Graham, 2003) and is colocalized with mesangial IgA1 deposits, we postulated that TGase2 could also be involved in IgA1 deposit stabilization in the mesangium. We therefore examined the in vitro interaction between TGase2 and TIR1. TGase2 strongly interacted with recombinant sTIR1 but not with an irrelevant recombinant protein, β-synuclein (Fig. 8 E). Direct TGase2–TIR1 interaction was demonstrated in pull-down assays using histidine-tagged sTIR1 as bait where TGase2 was retained and detected on Western blot (Fig. 8 F). In contrast, in the absence of sTIR1, TGase2 was not retained (Fig. 8 F). This interaction was also shown on HMCs in which binding of TGase2 was partially inhibited by recombinant sTIR1 (Fig. 8 G). We next examined whether TGase2 could amplify IgA1 binding to TIR1. Enhanced IgA1 binding to TIR1

**Figure 6.** sCD89–TIR1 interaction favors IgA1 deposition and activates mesangial cells. (A) HMCs were incubated with the IgA1 or IgA1–sCD89 complexes at 4°C, and binding was detected using anti–IgA-FITC. The graph shows the mean of IgA1 binding (±SEM) as a mean fluorescence intensity ratio to background of six independent experiments. (B) Cell surface colocalization of IgA1 and CD89 on HMCs after incubation with IgA1–sCD89 complexes on ice. Wheat germ agglutinin (WGA) was used as cell membrane marker. Bars, 2 µm. Since our first description of the putative role of sCD89 in generating mouse IgA deposits in the mesangium (Launay et al., 2000), there was a lack of formal demonstration that sCD89 actively participates in IgA1 mesangial deposition in mice and humans. The production of mice expressing both human IgA1 and human CD89 on monocytes/macrophages allowed us to readdress this question and to demonstrate that sCD89 is required for pathogenic mesangial IgA1 deposits leading to disease development. Interestingly, in the absence of CD89, IgA1 deposition occurring in α1KI mouse glomeruli did not lead to any detectable renal dysfunction, which is in line with observations in humans that not all subjects with IgA glomerulus deposition express overt signs of glomerulonephritis (Varis et al., 1993; Glassock, 2011). The spontaneous sCD89 production observed in mice that express human IgA1 and CD89 may be related to the high polymeric/monomeric ratio of IgA in the mouse. Indeed, although ~30% of circulating chimeric IgA1 (composed by a human α1 heavy chain and mouse λ and κ chains) were polymeric in both α1KI and α1KI-CD89Tg mice, in human normal serum, this form represents ~10% of total IgA (Mestecky, 1988; Kerr, 1990). Thus, small IgA1 complexes, mimicking complexes formed by underglycosylated IgA1 found in patients, may induce CD89 aggregation and shedding from myeloid cells in α1KI-CD89Tg mice as reported for human myeloid cells (Launay et al., 2000). This would result in the formation of circulating complexes containing IgA1 and sCD89 that would deposit in kidney mesangium. However, so far, there was no published evidence for mesangial sCD89 deposition in patients. Using a new polyclonal antibody raised against sCD89, we clearly detected CD89 in the mesangium of α1KI-CD89Tg mice and of IgAN patients. Acid elution procedure, a standard method to isolate antibodies and complexes from glomeruli (Woodroffe and Wilson, 1977), confirmed the presence of sCD89 in mesangial IgA1 deposits, further suggesting that the molecular mass of IgA1 complexes is a major factor promoting IgAN. In line with this observation, acidic elution of

![Figure 7](image-url)
Transglutaminase is crucial for IgA nephropathy | Berthelot et al.

and increased serum creatinine levels. Our data may support recent observations by others in which severity of renal dysfunction in IgAN patients correlates with the disappearance of IgA1–sCD89 complexes in the circulation, suggesting that this could be caused by their increased deposition in kidneys (Boyd and Barratt, 2010; Vuong et al., 2010). The large size of the deposited pathogenic aggregates observed in these mice that include IgA1, TfR1, TfR1-associated TGase2, and sCD89 and that may also include IgA1-associated MBL with their associated serine proteases (MASP; Roos et al., 2006) may explain why deposited mesangial sCD89 has escaped detection so far. Yet, the role of sCD89 in pathogenic mesangial deposits in our IgAN murine model stresses the importance of a systematic evaluation of CD89 presence in IgAN patient biopsies. Generation of adapted molecular tools, such as our new polyclonal anti-sCD89 antibody, will be important in this regard.

TfR1, a multiligand receptor, participates in several cellular functions (Lebrón et al., 1998; Radoshitzky et al., 2007; Schmidt et al., 2008). TfR1 is a receptor for IgA1 whose binding depends on the size and the glycosylation of IgA1 (Moura et al., 2004a). In pathology, cell surface overexpression of TfR1 is a major characteristic of IgAN and celiac disease (Moura et al., 2001; Haddad et al., 2003; Matysiak-Budnik et al., 2008).

IgA1–sCD89 complexes from kidney eluates was predominantly of high molecular mass, confirming previous data obtained with IgAN patients (Monteiro et al., 1985). Interestingly, sCD89 was also detected in serum as high molecular mass forms, suggesting that sCD89 could be covalently linked to IgA1. This in agreement with previous data showing that sCD89 can be covalently linked to IgA in a polymeric form (van der Boog et al., 2002). However, although in a previous study authors found a 30-kD sCD89 protein complexed with IgA in normal human sera (van der Boog et al., 2002), we observed a 50–70-kD sCD89 form that is exclusively found in the serum of IgAN patients (Launay et al., 2000). It is noteworthy that all sCD89 found in serum in α1KI-CD89Tg mice was associated with IgA1, demonstrating that no IgA-free sCD89 may exist in the circulation. It is also remarkable that in the absence of CD89, no high molecular mass IgA1 complexes were found in the circulation of α1KI mice. These IgA1–sCD89 complexes appeared nephrotoxic because only α1KI-CD89Tg mice developed renal failure as indicated by proteinuria, hematuria, TGase2, and sCD89 and that may also include IgA1-associated MBL with their associated serine proteases (MASP; Roos et al., 2006) may explain why deposited mesangial sCD89 has escaped detection so far. Yet, the role of sCD89 in pathogenic mesangial deposits in our IgAN murine model stresses the importance of a systematic evaluation of CD89 presence in IgAN patient biopsies. Generation of adapted molecular tools, such as our new polyclonal anti-sCD89 antibody, will be important in this regard.

Tfr1, a multiligand receptor, participates in several cellular functions (Lebrón et al., 1998; Radoshitzky et al., 2007; Schmidt et al., 2008). Tfr1 is a receptor for IgA1 whose binding depends on the size and the glycosylation of IgA1 (Moura et al., 2004a). Tfr1–IgA1 interaction plays a crucial role in physiology where polymeric IgA1 controls erythroblast proliferation and accelerates erythropoiesis recovery in anemia (Coulon et al., 2011). In pathology, cell surface overexpression of Tfr1 is a major characteristic of IgAN and celiac disease (Moura et al., 2001; Haddad et al., 2003; Matysiak-Budnik et al., 2008).
It acts predominantly as a cytosolic enzyme but can be externalized from cells by an unknown secretory pathway, after which it cross-links proteins of the extracellular matrix and induces renal fibrosis development (Fesus and Piacentini, 2002; Shweke et al., 2008). Our data reveal that TGase2 surface expression is induced by sCD89 and is up-regulated in the mesangium of \( \alpha 1KI-\) CD89Tg mice and in IgAN patients. The latter observation is in agreement with data reported by others showing increased mesangial TGase2 expression in IgAN patients (Ikee et al., 2007). Moreover, the correlation of TGase2 mesangial expression with deterioration of renal function (Ikee et al., 2007) supports our observations that only \( \alpha 1KI-\) CD89Tg mice that overexpress TGase2 develop proteinuria, whereas \( \alpha 1KI \) mice alone show no proteinuria and mild TGase2 overexpression, further suggesting that TGase2 controls the triggering of IgAN pathology. The mechanism by which TGase2 surface expression increases in turn surface expression of TIR1 remains unresolved whether it involves increased TIR1 gene transcription or interference in TIR1 cycle by favoring its recycling to, and stabilization at, the plasma membrane. Mesangial fibronectin expression is also up-regulated in \( \alpha 1KI-\) CD89Tg mice.
and colocalizes with TGase2 and IgA1. Interestingly, it has been shown that TGase2 binds to fibronectin and acts as an integrin coreceptor (Lordan and Graham, 2003), emphasizing that TGase2 could intervene at multiple levels in mesangial cell activation for inflammation and fibrosis in IgAN.

In conclusion, our study demonstrates that IgA1–CD89 complex could initiate a process of autoamplification involving hyperexpression of TIR1 and TGase2, allowing increased mesangial deposition of pathogenic IgA1 complexes and chronic mesangial cell activation. The critical role played by TGase2 revealed by our humanized mouse model opens new perspectives for pharmacological modulation of excessive TGase2 expression as a promising strategy for therapeutic intervention in IgAN.

MATERIALS AND METHODS

Subjects. Sera were obtained from 15 patients with biopsy-proven IgAN and no steroid treatment and from 25 healthy controls with their informed consent as requested for approval by the hospital ethical committee. Renal biopsy specimens from three patients with IgAN and two with minimal change disease were studied.

Mouse procedures. α1KI mice (Duchez et al., 2010), expressing the human IgA1, were backcrossed for 15 generations with C57BL/6 CD89Tg mice expressing the WT human CD89 on monococyte/macrophages (Launay et al., 2000). Mice on 129S2/SvPasCrl-C57BL/6J mixed background were used as WT controls to α1KI, CD89Tg, and α1KI–CD89Tg mice. TGase2−/− C57BL/6 mice generated as described previously (De Laurenzi and Melino, 2001) were provided by G. Melino (University of Rome Tor Vergata, Rome, Italy) and P.-L. Tharaux (Institut National de la Santé et de la Recherche Médicale Unité 970, Paris, France) and were backcrossed with α1KI–CD89Tg mice. All strains were raised and maintained at the mouse facilities of the Claude Bernard Institute. All experiments were performed in accordance with the national ethical guidelines and with the approval of local authorities of the Comité d’Éthique Experimentation Animale Bichat-Debré. Serum and kidneys were collected from 3–6, 12–24, and 40-wk-old male mice. 200 µg sCD89 was injected i.v. on days 0, 3, and 6 in kidneys were collected from 3-, 6-, 12-, 24-, and 40-wk-old male mice. 200 µg with the national ethical guidelines and with the approval of local authorities Claude Bernard Institute. All experiments were performed in accordance with the national ethical guidelines and with the approval of local authorities

Kidney functional parameters. Protein, albumin, and creatinine levels were measured in urines and creatinine levels in sera of mice using the AU400 chemistry analyzer (Olympus). For hematuria, 10 µl of fresh urines were mounted on a Malassez hemocytometer, and red cells were counted.

HPLC. 300 µl of serum or 500 µg of kidney–eluted proteins diluted in PBS was resolved by gel filtration through a Superdex 200 10/30 column (GE Healthcare) connected to an HPLC AKTA-basic automated liquid chromatography system (GE Healthcare).

Immunoblot analysis. Sera or HPLC fractions were solubilized in SDS sample buffer under nonreducing conditions and subjected to electrophoresis in 6% polyacrylamide gel. Proteins were electrophoretically transferred to polyvinylidene difluoride membranes (Millipore) and subjected to Western blot analysis using a biotinylated goat anti-human IgA (SouthernBiotech) and streptavidin coupled to horseradish peroxidase (HRP). Membranes were developed by enhanced chemiluminescence treatment (GE Healthcare). For serum immunoprecipitation assays, CD89-containing complexes were immunoprecipitated for 1 h at room temperature with mAb A3 coupled to CNBr-activated Sepharose 4B beads (GE Healthcare) followed by SDS–10% PAGE at nonreducing conditions and analyzed by Western blotting using a cocktail of anti-CD89 and anti-TFRC antibodies plus anti–rabbit coupled with HRP.

Cells, flow cytometry, and immunofluorescence. Spleenocytes and cells from blood samples from WT, α1KI, CD89Tg, and α1KI–CD89Tg mice were stained with anti–mouse CD11b–PE-Cy7 and anti–CD89–PE antibodies (BD). Primary HMCs were purchased from Lonza and cultured as described previously (Moura et al., 2004a). Binding to HMCs was analyzed by flow cytometry using a FACSCanto II (BD). HMCs were incubated with different concentrations of α1KI mouse IgA1, biotinylated TGase, or sCD89 in successive steps on ice before washings and analysis. Complexes were formed by incubation of proteins for 1 h at 37°C. BSA was used as a negative control. The interaction with TIR1 was evaluated by using sTIR1 as a specific inhibitor. For binding inhibition, proteins were incubated with sTIR1 for 1 h on ice and then incubated with cells. Binding was evaluated using FITC–labeled anti–human IgA, streptavidin–allophycocyanin (APC) or anti–human CD89 mAb (A59–PE; BD). To examine the expression of TIR1 and TGase2, quiescent HMCs were cultured with or without sCD89. After 48-h incubation, TIR1
and TGase2 expression was analyzed by flow cytometry using an anti–Tlr1-PE mAb (BD) or a biotinylated anti–TGase2 polyclonal antibody (Thermo Fisher Scientific), respectively. Cytokine (IL-8, IL-6, and TNF-α) production in the HMC culture supernatants was measured using ELISA DuoSet kits (R&D Systems) at 8 or 48 h. For immunofluorescence, HMCs were cultured on 4-well permanox Lab-Tek chamber slides in complete RPMI medium (15,000 cells/well). After 24 h, HMCs were incubated for 1 h at 4°C with preformed complexes of IgA1 and recombinant sCD89 and fixed with 2% paraformaldehyde in PBS for 15 min at room temperature. Non-specific labeling was avoided by two 10-min incubations with sodium borohydride (NaBH₄) at 1 mg/ml followed by incubation in 4% BSA for 30 min. Cells were then labeled with a rabbit polyclonal anti–CD89 in PBS for 1.67 h, followed by two washes with PBS. Slides were mounted with Vectashield (Dako) and read with a confocal microscope (TCS SP5 II; Leica).

Human transferrin receptor gene silencing. Lentiviral vectors for human TLR1 and irrelevant control miRNA were built with the BLOCK-i-T Lenti-viral Pol II miR RNA Expression System (Invitrogen). DNA sequences were designed using the BLOCK-i-T RNAi Designer according to the manufacturer’s recommendations and synthesized (Operon MWG). DNA oligonucleotide sequences were inserted into pcDNA6.2 vectors and transfected to pLenti6-BLOCK-i-T vectors by DNA recombination. To generate lentiviral stocks, 6 × 10⁶ 293T cells were transfected with 3 µg pLenti6/BLOCK-i-T-miR-human TLR1, along with 9 µg Vi-PhaPower (pLP1, pLIP2, and pLP/VSVG; Invitrogen) in Opti-MEM I (Invitrogen) without antibiotics. Cells were cultured for 72 h, and culture medium was collected, centrifuged at 4°C, 3,000 rpm for 15 min, and stored at −80°C. HMCs were infected with lentivirus in RPMI (Invitrogen) and in the presence of 6 µg/ml Polybrene (Sigma-Aldrich). Cell phenotype was analyzed 48–72 h after infection.

Quantitative real-time PCR analysis. Kidneys were homogenized, and RNA was purified using the RNeasy Plus Mini kit (QIAGEN). 700 ng RNA was reverse transcribed using a Quantitect RT kit (QIAGEN). Resulting cDNA was used as template for quantitative PCR analysis. Primers were purchased from Eurofins and were as follows: GAPDH, 5′-ACGGCAATCTAACGCACAGTCTA-3′ (sense) and 5′-TGTTGGGATTCCGGAG-3′ (antisense); IFN-α, 5′-GCTTGTGATGTCAACGCCC-3′ (sense) and 5′-CACGGCAAGTTGCTCCTCTCTA-3′ (antisense); IL-6, 5′-CAGCTGTCCTTCA-3′ (sense) and 5′-GCCATTCGACACCTTTCTCATCAT-3′ (antisense); and TNF, 5′-AGGGACCTCCTCCAAAAAGATG-3′ (sense) and 5′-TACCCAGGATGTCGAGACGA-3′ (antisense). Gene quantification was performed in duplicate using a Chromo4 Real-Time PCR Detection System (Bio-Rad Laboratories). Data were normalized to GAPDH values.

ELISA. Plates were coated overnight with F(ab′)₂ goat anti–human IgA (10 µg/ml; SouthernBiotech) or A3 mAb (10 µg/ml) or were directly coated with histidine-tagged TLR1 or β-synuclein or IgA1 and albumin (10 µg/ml). Sera or HPLC fractions were incubated in the wells in PBS, containing 0.05% Tween, 0.1% sodium azide, and 1% BSA overnight. After washing, the anti-human IgA mAb coupled with the alkaline phosphatase (AP; BD) was added at 1:2,000 dilution for 1 h. For binding tests, biotinylated sCD89 or Tgase was incubated for 2 h, and after washing, streptavidin-AP (Jackson ImmunoResearch Laboratories, Inc.) was added at 1:10,000 dilution for 30 min. The reaction was developed by adding the AP substrate (SIGMAFAST p-nitrophenyl phosphate tablets; Sigma-Aldrich).

Surface plasmon resonance assays. All the assays were performed on a Biacore X100 (GE Healthcare). The antibody A3 against CD89 was immobilized on two flow cells of a CMS carboxymethylated dextran biosensor chip (GE Healthcare) using carbodiimide chemistry. After capture of sCD89 on one flow cell, the different purified IgAs, mouse IgA (myeloma IgA; MP Biomedicals), human IgA1 (purified from healthy control serum using jaca-lin), and α1KI mouse IgA1 (myeloma IgA1, purified using DEAE column), were injected for 2 min on the two flow cells. The association and dissociation profiles were double-referenced (i.e., both the signal from the reference surface with A3 alone and from blank buffer injections were subtracted) and analyzed using the BiACore analysis software.

Statistical analysis. Nonparametric Mann-Whitney tests were performed for the different comparisons between different groups of mice and between healthy controls and IgAN patients. A p-value of <0.05 was considered significant.

We thank Anissa Bouhalfaia and Nathalie Ialy-Radio for animal breeding, Olivier Thibaudeau for kidney sections, Samira Benadda and Xavier Bauduin for confocal microscopy analysis, Alain Grodet for transmission electron microscopy, and Gerry Melino and Pierre-Louis Tharaux for providing Tgase2−/− mice. This work was supported by Agence Nationale de la Recherche. L. Berthelot was supported by the French Society of Nephrology and the European Renal Association–European Dialysis and Transplant Association.
