CANONICAL FRAGMENTS OF THE STRONG REFLECTION PRINCIPLE

GUNTER FUCHS

Abstract. For an arbitrary forcing class $\Gamma$, the $\Gamma$-fragment of Todorčević’s strong reflection principle $\text{SRP}$ is isolated in such a way that (1) the forcing axiom for $\Gamma$ implies the $\Gamma$-fragment of $\text{SRP}$, (2) the stationary set preserving fragment of $\text{SRP}$ is the full principle $\text{SRP}$, and (3) the subcomplete fragment of $\text{SRP}$ implies the major consequences of the subcomplete forcing axiom. Along the way, some hitherto unknown effects of (the subcomplete fragment of) $\text{SRP}$ on mutual stationarity are explored, and some limitations to the extent to which fragments of $\text{SRP}$ may capture the effects of their corresponding forcing axioms are established.

1. INTRODUCTION

The strong reflection principle, $\text{SRP}$, introduced by Todorčević (see [6, P. 57]), follows from Martin’s Maximum, and encompasses many of the major consequences of Martin’s Maximum: the singular cardinal hypothesis, that $2^{\omega_1} = \omega_2$, that the
nonstationary ideal on $\omega_1$ is $\omega_2$-saturated, and many others; see [26, Chapter 37] for an overview. In [17], I began a detailed study of the consequences of SCFA, the forcing axiom for subcomplete forcing, with an eye to its relationship to Martin’s Maximum. Subcomplete forcing was introduced by Jensen [31], [33], and shown to be iterable with revised countable support. Since subcomplete forcing notions cannot add reals, SCFA is compatible with CH, which sets it apart from Martin’s Maximum. In fact, Jensen [30] showed that SCFA is even compatible with $\diamondsuit$, and hence does not imply that the nonstationary ideal on $\omega_1$ is $\omega_2$-saturated. On the other hand, SCFA does have many of the major consequences of Martin’s Maximum, such as the singular cardinal hypothesis, as mentioned above.

While my quest to deduce consequences of Martin’s Maximum from SCFA (or some related forcing principles for subcomplete forcing) has been fairly successful in many respects, such as the failure of (weak) square principles and the reflection of stationary sets of ordinals [20], and even the existence of well-orders of $\mathcal{P}(\omega_1)$ [19], it remained unclear until recently how to find an analog of SRP that relates to SCFA like SRP relates to Martin’s Maximum. Thus, I was looking for a version of SRP that follows from SCFA and that, in turn, implies the major consequences of SCFA.

The objective of the present article is to provide such a principle. In fact, I canonically assign to any forcing class $\Gamma$ its fragment of the strong reflection principle, which I call $\Gamma$-SRP, in such a way that

1. the forcing axiom for $\Gamma$, FA($\Gamma$), implies $\Gamma$-SRP,
2. letting SSP be the class of all stationary set preserving forcing notions, SRP is equivalent to SSP-SRP,
3. letting SC be the class of all subcomplete forcing notions, SC-SRP captures many of the major consequences of SCFA.

While points [1] and [2] are beyond dispute, point [3] is a little vague, and I will give some more details on which consequences of SCFA the principle SC-SRP captures and which it cannot. The situation will turn out to be similar to the SRP vs. MM comparison.

For the most part, I will be working with a technical simplification of the notion of subcompleteness, called $\infty$-subcompleteness and introduced in Fuchs-Switzer [24]. This leads to a simplification of the adaptation of projective stationarity to the context of this version of subcompleteness. Working with the original notion of subcompleteness would add some technicalities, but would not change much otherwise.

The paper is organized as follows. In Section 2 I give some background on the strong reflection principle and on generalized stationarity. Given a forcing class $\Gamma$, I introduce the notion of $\Gamma$-projective stationarity and the $\Gamma$-fragment of SRP, and I show that the forcing axiom for $\Gamma$ implies the $\Gamma$-fragment of SRP, as planned. I then review the definitions of subcomplete and $\infty$-subcomplete forcing and characterize ($\infty$-)subcomplete projective stationarity combinatorially (as being “(fully) spread out”).

Section 3 is concerned with consequences of SRP, and mainly of the subcomplete fragment of SRP. The main task here is to show that certain stationary sets are not only projective stationary, but even spread out. To this end, I give some background on Barwise theory and prove a technical lemma in Subsection 3.1. Subsection 3.2 then uses this in order to establish that some of the major consequences of SRP
already follow from the subcomplete fragment of SRP: Friedman’s problem, the
failure of square and the singular cardinal hypothesis. In Subsection 3.3, I derive
some consequences of SRP, and its subcomplete fragment, on mutual stationarity
(which as far as I know are new even as consequences of the full SRP).

Section 4 deals with limitations to the effects of the subcomplete fragment of SRP
on certain diagonal reflection principles for stationary sets of ordinals, and with the
task of separating it from SCFA. In Subsection 4.1, I show that the ∞-subcomplete
fragment of SRP is consistent with a failure of reflection at ω₂, assuming the con-
sistency of an indestructible version of SRP. I also observe that, assuming the
consistency of an indestructible version of SRP (that follows from MM), ∞-SC-SRP
does not imply SCFA. This follows rather directly from prior results. However these
results don’t separate the subcomplete fragment of SRP, together with CH, from
SCFA. The last two subsections contain partial results in this direction. Subsec-
tion 4.2 shows that, assuming the consistency of an indestructible version of the
fragment of SRP used to deduce the consequences in Section 3, together with
CH, that fragment with CH fails to imply a rather weak diagonal reflection principle at
ω₂ which does follow from SCFA + CH, thus separating this fragment of SRP in the
presence of CH from SCFA. Finally, in Section 4.3, I show that if the subcomplete
forcing axiom up to ω₂ (I denote this BSCFA(≤ω₂)) is consistent, then it is consist-
tent that CH and the subcomplete fragment of SRP(ω₂) hold, but BSCFA(≤ω₂) fails.
In this last result, it matters in the proof that I deal with subcompleteness, not
∞-subcompleteness. Along the way, I show that complete forcing that preserves
uncountable cofinalities is iterable with countable support.

Finally, Section 5 lists some questions and open problems.

2. Γ-PROJECTIVE STATIONARITY AND THE Γ-FRAGMENT OF SRP

In this section, I will give a brief introduction to the strong reflection principle,
motivate how I arrive, for a forcing class Γ, at the Γ-fragment of the strong reflec-
tion principle, consider a couple of examples, and then focus on the subcomplete
fragment of SRP.

2.1. Some background and motivation for SRP. Recall Friedman’s problem from [15]:

Definition 2.1. If γ < κ, then I write $S^γ_κ$ for the set of ordinals ξ < κ with
cf(ξ) = γ. Now let κ ≥ ω₂ be an uncountable regular cardinal. Then Friedman’s
Problem at κ, denoted FP_κ, says that whenever $S \subseteq S^κ_ω$ is stationary, then there
is a normal (that is, increasing and continuous) function $f : ω_1 \to S$. In other
words, S contains a closed set of order type $ω_1$.

The strong reflection principle SRP, introduced by Todorčević (see [6] or [37] for
its original formulation), can be viewed as a version of Friedman’s problem, but
adapted to the generalization of stationarity due to Jech, see [27] for an overview
article. The role of a closed set of order type $ω_1$ is taken over by the obvious analog
for the context of generalized stationarity: a continuous $∈$-chain of length $ω_1$. I
deviate slightly from the common way of presenting this.

Definition 2.2. Let κ be a regular uncountable cardinal, and let $S \subseteq [H_κ]^κ$ be
stationary. A continuous $∈$-chain through $S$ of length λ is a sequence $\langle X_i | i < λ \rangle$
of members of S, increasing with respect to $∈$, such that for every limit $j < λ,$
$X_j = \bigcup_{i<j} X_i.$
Feng & Jech [11] found an equivalent way to express Todorčević’s original principle that is more amenable to generalization than its original formulation. They introduced the following concept.

**Definition 2.3.** Let $\kappa$ be an uncountable regular cardinal. $S \subseteq [H_\kappa]^{\omega}$ is *projective stationary* if for every stationary set $T \subseteq \omega_1$, the set $\{X \in S \mid X \cap \omega_1 \in T\}$ is stationary.

While I’m at it, let me introduce some terminology around generalized stationarity.

**Definition 2.4.** Let $\kappa$ be a regular cardinal, and let $A \subseteq \kappa$ be unbounded. Let $\kappa \subseteq X$. Then

$$\text{lifting}(A, [X]^{\omega}) = \{x \in [X]^{\omega} \mid \sup(x \cap \kappa) \in A\}$$

is the lifting of $A$ to $[X]^{\omega}$. Now let $S \subseteq [X]^{\omega}$ be stationary. If $W \subseteq X \subseteq Y$, then we define the projections of $S$ to $[Y]^{\omega}$ and $[W]^{\omega}$ by

$$S \uparrow [Y]^{\omega} = \{y \in [Y]^{\omega} \mid y \cap X \in S\}$$

and

$$S \downarrow [W]^{\omega} = \{x \cap W \mid x \in S\}.$$  

Thus, using this notation, and letting $\kappa$ be an uncountable regular cardinal, a set $S \subseteq [H_\kappa]^{\omega}$ is projective stationary iff for every stationary $T \subseteq \omega_1$, $S \cap (T \uparrow [H_\kappa]^{\omega})$ is stationary. It is well-known that in the notation of the previous definition, $S \uparrow [Y]^{\omega}$ and $S \downarrow [W]^{\omega}$ are stationary.

Following is the characterization of SRP, due to Feng and Jech, which I take as the official definition.

**Definition 2.5.** Let $\kappa \geq \omega_2$ be regular. Then the strong reflection principle at $\kappa$, denoted $\text{SRP}(\kappa)$, states that whenever $S \subseteq [H_\kappa]^{\omega}$ is projective stationary, then there is a continuous $\in$-chain of length $\omega_1$ through $S$. The strong reflection principle $\text{SRP}$ states that $\text{SRP}(\kappa)$ holds for every regular $\kappa \geq \omega_2$.

Usually, the strong reflection principle is formulated so as to assert the existence of an elementary chain of length $\omega_1$ through $S$. We’ll briefly convince ourselves that this version of the principle, made precise, follows from the one stated.

**Observation 2.6.** Projective stationarity is preserved by intersections with clubs: if $S \subseteq [H_\kappa]^{\omega}$ is projective stationary, where $\kappa$ is regular and uncountable, then for any club $C \subseteq [H_\kappa]^{\omega}$, $S \cap C$ is also projective stationary.

*Proof.* Let us fix $S$ and $C$. Let $T \subseteq \omega_1$ be stationary and $D \subseteq [H_\kappa]^{\omega}$ be club. Then, since $S$ is projective stationary, it follows that

$$\{X \in S \mid X \cap \omega_1 \in T\} \cap (C \cap D) \neq \emptyset.$$  

But the set on the left is equal to

$$\{X \in S \cap C \mid X \cap \omega_1 \in T\} \cap D,$$  

and this shows that $S \cap C$ is projective stationary.  

In the following, for a model $\mathcal{M}$ of a first order language, I write $|\mathcal{M}|$ for its universe. Further, if $X \subseteq |\mathcal{M}|$, then $\mathcal{M}|X$ is the restriction of $\mathcal{M}$ to $X$.
Corollary 2.7. Assume SRP(κ). Let $S \subseteq [H_\kappa]^\omega$ be projective stationary. Let $\mathcal{M} = (H_\kappa, \in | [H_\kappa, \ldots])$ be a first order structure of a finite language.\footnote{Since $H_\kappa$ is closed under ordered pairs, it is easy to code any countable language into a finite language, and it will sometimes be convenient to assume that the language at hand is finite, so I will usually make that assumption.} Then there is a continuous elementary chain $\langle \mathcal{M}_i | i < \omega_1 \rangle$ of elementary submodels of $\mathcal{M}$ through $S$, meaning that, for all $i < \omega_1$, $[\mathcal{M}_i] \in S$, $\mathcal{M}_i \in [\mathcal{M}_{i+1}]$, $\mathcal{M}_i \prec \mathcal{M}_{i+1}$ and if $i$ is a limit ordinal, then $[\mathcal{M}_i] = \bigcup_{j < i} [\mathcal{M}_j]$.

Proof. This follows immediately from the previous observation, since $\mathcal{C} = \{X \in [H_\kappa]^\omega | (\mathcal{M}|X) \prec \mathcal{M}\}$ contains a club. Any continuous chain $\langle X_i | i < \omega_1 \rangle$ through $S \cap \mathcal{C}$ gives rise to a continuous elementary chain of models by setting $\mathcal{M}_i = \mathcal{M}|X_i$. Note that, for $i < \omega_1$, since $X_i \subseteq X_{i+1}$, it follows that $\mathcal{M}_{i+1}$ sees that $X_i$ is countable, as $\mathcal{M}_{i+1} \prec \mathcal{M}$, and hence, $X_i \subseteq X_{i+1}$ and $\mathcal{M}_i \prec \mathcal{M}_{i+1}$. Also, since $\mathcal{M}_i$ is definable from $X_i \in [\mathcal{M}_{i+1}]$, as the language of $\mathcal{M}$ is finite, it follows that $\mathcal{M}_i \in [\mathcal{M}_{i+1}]$.

The key to showing that Martin’s Maximum implies SRP is that the canonical forcing to shoot a continuous $\in$-chain of length $\omega_1$ through a projective stationary set, described in the following definition, preserves stationary subsets of $\omega_1$.

Definition 2.8. $\mathbb{P}_S$ is the forcing notion consisting of continuous $\in$-chains through $S$ of countable successor length, ordered by end-extension. For $p \in \mathbb{P}_S$, I write $p = (M^p_i | i \leq \ell^p)$.

The following fact is essentially contained in Feng & Jech [11], even though it is not explicitly stated.

Fact 2.9. Let $\kappa$ be an uncountable regular cardinal, and let $S \subseteq [H_\kappa]^\omega$ be stationary. Then

1. For every countable ordinal $\alpha$, the set of conditions $p$ with $\ell^p \geq \alpha$ is dense in $\mathbb{P}_S$.
2. For every $a \in H_\kappa$, the set of conditions $p$ such that there is an $i < \ell^p$ with $a \in M^p_i$ is dense in $\mathbb{P}_S$.
3. $\mathbb{P}_S$ is countably distributive.

Proof. We prove clauses [1] and [2] simultaneously. Let $p \in \mathbb{P}_S$, $\alpha < \omega_1$, and $a \in H_\kappa$ be given. We use Lemma 1.2 of [11], which states that if $T \subseteq [H_\kappa]^\omega$ is stationary, then, for every countable ordinal $i$, there is a continuous $\in$-chain through $T$ of length at least $i + 1$. Let $T = \{M \subseteq S | a, M^p \in M\}$. Clearly, $T$ is stationary, so by the lemma, let $\langle N_i | i \leq \beta \rangle$ be a continuous elementary chain through $T$, with $\beta \geq \alpha$. Let $\gamma = \ell^p + 1 + \beta + 1$, and define a condition $q = (M^q_i | i < \gamma)$ by setting $M^q_i = M^p_i$ for $i \leq \ell^p$ and $M^q_{\ell^p + 1 + j} = N_j$ for $j \leq \beta$. Then $q \leq p$ has length at least $\alpha + 1$ and eventually contains $a$, as wished.

In order to prove clause [3] we have to show that, given a sequence $\bar{D} = \langle D_n | n < \omega \rangle$ of dense open subsets of $\mathbb{P}_S$, the intersection $\Delta = \bigcap_{n < \omega} D_n$ is dense in $\mathbb{P}_S$. So, fixing a condition $p \in \mathbb{P}_S$, we have to find a $q \leq p$ in $\Delta$. To this end, let $\lambda$ be a regular cardinal much greater than $\kappa$, say $\lambda > 2^{2^{[\mathbb{P}_S]}}$, and consider the model $\mathbb{N} = (H_\lambda, \in, \leq, S, \mathbb{P}_S, \bar{D}, p)$, where $\leq$ is a well-ordering of $H_\lambda$. Let $\mathcal{M} \prec \mathbb{N}$ be a countable elementary submodel with $|\mathcal{M}| \cap H_\kappa \subseteq S$. Since $\mathcal{M}$ is countable, we can pick a filter $G$ which is $\mathcal{M}$-generic for $\mathbb{P}_S$ and contains $p$. Let $\bar{q} = \bigcup G$. Using the
density facts proved in [1] and [2], it follows that \( \delta := \text{dom}(\overline{q}) = M \cap \omega_1 \), and that \( \bigcup_{i<\delta} \overline{q}(i) = M \cap \kappa \in S \). Thus, if we define the sequence \( q \) of length \( \delta + 1 \) by setting \( q(i) = \overline{q}(i) \) for \( i < \delta \) and \( q(\delta) = M \cap \kappa \), then \( q \in \mathbb{P}_S \), and \( q \) extends every condition in \( G \). Moreover, since \( D_n \in M \), for each \( n < \omega \), it follows that \( G \) meets each \( D_n \), and hence that \( p \geq q \in \Delta \), as desired. \( \Box \)

**Fact 2.10** (Feng & Jech). Let \( \kappa \geq \omega_2 \) be an uncountable regular cardinal. Then a stationary set \( S \subseteq [H_\kappa]^\omega \) is projective stationary iff \( \mathbb{P}_S \) preserves stationary subsets of \( \omega_1 \).

For the proof of this fact, see Feng & Jech [11] – one direction is given by the proof of Theorem 1.1, and the converse is outlined in the paragraph after the proof, on page 275.

2.2. Relativizing to a forcing class.

**Definition 2.11.** I write SSP for the class of all forcing notions that preserve stationary subsets of \( \omega_1 \).

With hindsight, the results in the previous subsection show that the strong reflection principle can be formulated as follows.

\[
\text{Whenever } \kappa \geq \omega_2 \text{ is regular, } S \subseteq [H_\kappa]^\omega \text{ is stationary, and the forcing } \mathbb{P}_S \text{ to shoot a continuous elementary chain through } S \text{ is in SSP, then } S \text{ already contains a continuous } \in \text{-chain of length } \omega_1.
\]

The advantage of this formulation is that it generalizes easily to arbitrary forcing classes. First, let me generalize the concept of projective stationarity.

**Definition 2.12.** Let \( \Gamma \) be a forcing class. Then a stationary subset \( S \) of \( H_\kappa \), where \( \kappa \geq \omega_2 \) is regular, is \( \Gamma \)-projective stationary iff \( \mathbb{P}_S \in \Gamma \).

Thus, the Feng-Jech notion of projective stationarity is the same thing as SSP-projective stationarity. Generalizing the above formulation of SRP, we arrive at:

**Definition 2.13.** Let \( \Gamma \) be a forcing class. Let \( \kappa \geq \omega_2 \) be regular. The \( \Gamma \)-fragment of the strong reflection principle at \( \kappa \), denoted \( \Gamma \text{-SRP}(\kappa) \), states that whenever \( S \subseteq [H_\kappa]^\omega \) is \( \Gamma \)-projective stationary, then \( S \) contains a continuous chain of length \( \omega_1 \). The \( \Gamma \)-fragment of the strong reflection principle, \( \Gamma \text{-SRP} \), states that \( \Gamma \text{-SRP}(\kappa) \) holds for every \( \kappa \geq \omega_2 \).

The idea is that the collection of the \( \Gamma \)-projective stationary sets captures exactly those sets whose instance of the strong reflection principle follows from the forcing axiom for \( \Gamma \) using the simplest possible argument, namely that \( \mathbb{P}_S \) is in \( \Gamma \). Let me make this precise. First, by the forcing axiom for \( \Gamma \), I mean the version of Martin’s Axiom \( \text{MA}_{\omega_1} \) for \( \Gamma \) rather than the collection of all ccc partial orders.

**Definition 2.14.** Let \( \Gamma \) be a class of forcing notions. The forcing axiom for \( \Gamma \), denoted \( \text{FA}(\Gamma) \), states that whenever \( \mathbb{P} \) is a forcing notion in \( \Gamma \) and \( \langle D_i \mid i < \omega_1 \rangle \) is a sequence of dense subsets of \( \mathbb{P} \), there is a filter \( F \subseteq \mathbb{P} \) such that for all \( i < \omega_1 \), \( F \cap D_i \neq \emptyset \).

It is now easy to check that \( \Gamma \text{-SRP} \) behaves as claimed in the introduction.

**Observation 2.15.** Let \( \Gamma \) be a forcing class. Then \( \text{FA}(\Gamma) \) implies \( \Gamma \text{-SRP} \).
**Proof.** Let $\kappa \geq \omega_2$ be regular, and let $S \subseteq [H_\kappa]^{\omega}$ be $\Gamma$-projective stationary. Then $P_S \in \Gamma$, and, for $i < \omega_1$, we can let $D_i$ be the set of conditions in $P_S$ of length at least $i$. By clause [1] of Fact 2.20, $D_i$ is a dense subset of $P_S$. So by FA(\Gamma), there is a filter $F$ meeting each $D_i$. But then $\bigcup F$ is a continuous $\in$-chain through $S$. □

The utility of SRP is, of course, that it encapsulates many of the consequences of the forcing axiom for stationary set preserving forcing without mentioning forcing. Thus, in order to arrive at a similarly useful version of it for other forcing classes, it will be crucial to express $\Gamma$-projective stationarity in a purely combinatorial way that does not mention $\Gamma$ explicitly.

As an illustration, let’s look at two examples.

**Example 2.16.** Let Proper be the class of all proper forcing notions, and let’s consider the notion of projective stationarity associated to that class. It is then not hard to see that:

**Observation 2.17.** Let $\kappa \geq \omega_2$ be regular. Then a stationary set $S \subseteq [H_\kappa]^{\omega}$ is Proper-projective stationary iff $S$ contains a club.

**Proof.** For the forward direction, suppose that $S$ is Proper-projective stationary, that is, $P_S$ is proper. One of the many characterizations of properness is the preservation of stationary subsets of $[X]^{\omega}$, for any uncountable $X$. Now $P_S$ shoots a club through $S$, and this means that the complement $[H_\kappa]^{\omega} \setminus S$ could not have been stationary in $V$, since its stationarity would be killed by $P_S$. But this means that $S$ contains a club.

For the converse, suppose that $S$ contains a club $C \subseteq [H_\kappa]^{\omega}$. Let $\theta$ be sufficiently large, and let $M$ be a countable elementary submodel of $\langle H_\kappa, \in, <^* \rangle$, with $P_S, C \in M$. Let $p \in P_S \cap M$. Let $N = M^p_\kappa$. Since $M$ believes that $C$ is club in $H_\kappa$, it is now easy to construct an $\in$-chain $\langle N_i \mid i < \omega \rangle$ so that $N \in N_0, N_i \in M$ and $\bigcup_{i<\omega} N_i = M \cap H_\kappa$. It is then routine to verify that the condition $q = p \forces \check{N}^\check{\omega} (M \cap H_\kappa)$ is $(M, P_S)$-generic. □

Since any club contains a continuous $\in$-chain of length $\omega_1$, the proper fragment of SRP is thus provable in ZFC.

**Example 2.18.** For an example going in the other extreme, let Semiproper be the class of semiproper partial orders. In [12], a set $S \subseteq [\kappa]^{\omega}$ is defined to be spanning if for every $\lambda \geq \kappa$ and every club $C \subseteq [\lambda]^{\omega}$, there is a club $D \subseteq [\lambda]^{\omega}$ such that for every $x \in D$, there is a $y \in C$ such that $x \subseteq y$ and $x \cap \omega_1 = y \cap \omega_1$. It is shown in [12] Theorem 4.4] that $S$ is spanning iff $P_S$ is semiproper, that is, using our terminology, $S$ is spanning iff it is Semiproper-projective stationary. However, [12] Cor. 5.4] can be expressed as saying that Semiproper-SRP implies SRP, so the semiproper fragment of SRP is equivalent to the full principle SRP.

### 2.3. The subcomplete fragment of SRP

In the previous subsection, we have seen that the class of all proper forcing notions is too small to be of interest, in the sense that Proper-SRP is provable in ZFC, and the class of all semiproper forcing notions is too large to be of interest, in the sense that Semiproper-SRP is equivalent to the full principle SRP, and so is nothing new. So let us now get ready to define when a forcing notion is subcomplete, so that we can turn to the subcomplete fragment of SRP.
Definition 2.19 (Jensen). A transitive model $N$ of $\text{ZFC}^-$ is **full** if there is an ordinal $\gamma > 0$ such that $L_\gamma(N) \models \text{ZFC}^-$ and $N$ is regular in $L_\gamma(N)$, meaning that if $a \in N$, $f : a \rightarrow N$ and $f \in L_\gamma(N)$, then $\text{ran}(f) \in N$. A possibly nontransitive but well-founded model of $\text{ZFC}^-$ is full if its transitive isomorph is full.

The notion of fullness is central to the theory of subcomplete forcing, and so, it seems worthwhile to elaborate on it a little bit, since it is somewhat subtle. First off, when I say that $N$ is a transitive model of $\text{ZFC}^-$, I mean that $N$ is a model of a countable language which may extend the language of set theory, in which the symbol $\bar{e}$ is interpreted as the actual $e$ in relation, restricted to $N$, and that $N$ satisfies the usual axioms of $\text{ZFC}^-$, with respect to its language, that is, the formulas in the axiom schemes are allowed to contain the additional symbols available in the language of $N$. There is a subtlety in the concept of fullness, then, since whether or not a model $N$ is full depends on the way it is represented. For a simple example, let’s assume that $N$ is a countable full model of $\text{ZFC}^-$ in the language of set theory. Now let us consider $N_0$ to be like $N$, except that $N_0$ has a constant symbol $c_a$ for every $a \in N_0$, so that $c_a^{N_0} = a$. Clearly, $N_0$ is also a model of $\text{ZFC}^-$, and $N_0$ is also full. Now let $N_1$ be like $N$, but equipped with constant symbols $d_0, d_1, \ldots$, interpreted as $d_n^N = f(n)$, where $f : \omega \rightarrow N$ is a bijection. In a model-theoretic sense, $N_0$ and $N_1$ are essentially the same, it is just that their constant symbols are different. However, $N_0$ is full, while $N_1$ is not, since in $L_\gamma(N_1)$, the function $n \mapsto d_n^N = f(n)$ is available, and hence the fact that $N_1$ is countable is revealed. Thus, in order to make sense of the definition of fullness, one has to view the model $N$ as the triple $\langle |N|, L, I \rangle$, where $|N|$ is the universe of $N$, $L$ is the language of $N$ in an explicitly given Gödelization (since this example shows that it is important what the symbols in the language are), and $I$ is the function assigning each element of $L$ its interpretation in $N$. In the context of subcomplete forcing, the model $N$ in question will always be a model of a language with just one additional predicate symbol (which avoids the complications just mentioned). In fact, it will always be the result of constructing relative to some set. The notation I use for relative constructibility follows Jensen’s conventions: for a class $A$, define recursively:

- $L_0[A] = \emptyset$, $L_0^A = \langle \emptyset, \emptyset, \emptyset \rangle$,
- $L_{\alpha+1}[A] = \text{Def}(L^A_\alpha \cup L^A_\alpha)$,
- $L_\lambda[A] = \bigcup_{\alpha < \lambda} L_\alpha[A]$ and $L^A_\lambda = \langle L^A_\lambda[A], \in \cap L^A_\lambda[A] \rangle$.

**Definition 2.20.** The **density** of a poset $P$, denoted $\delta(P)$, is the least cardinal $\delta$ such that there is a dense subset of $P$ of size $\delta$.

I can now define Jensen’s notion of subcompleteness and its simplification, $\infty$-subcompleteness, introduced in [24].

**Definition 2.21.** A forcing notion $P$ is **subcomplete** if every sufficiently large cardinal $\theta$ verifies the subcompleteness of $P$, which means that $P \in H_\theta$, and for any $\text{ZFC}^-$ model $N = L^A_\theta$ with $\theta < \tau$ and $\text{ran}(\sigma) \in N$, any $\sigma : \bar{N} \prec N$ such that $\bar{N}$ is countable, transitive and full and such that $P, \theta \in \text{ran}(\sigma)$, any $G \subseteq P$ which is $\bar{N}$-generic over $\bar{N}$, any $\bar{s} \in \bar{N}$, and any ordinals $\bar{\lambda}_0, \ldots, \bar{\lambda}_{n-1}$ such that $\bar{\lambda}_0 = \text{On} \cap \bar{N}$ and $\bar{\lambda}_1, \ldots, \bar{\lambda}_{n-1}$ are regular in $\bar{N}$ and greater than $\delta(P)^{\bar{N}}$, the following holds. Letting $\sigma(\bar{\theta}, \bar{P}) = \langle \bar{\theta}, \bar{P} \rangle$, and setting $\bar{S} = \langle \bar{s}, \bar{\theta}, \bar{P} \rangle$, there is a condition $p \in P$ such that

\[ \sigma(\bar{\theta}, \bar{P}) = \bar{S} \quad \text{and} \quad \bar{S} \in \bar{N}. \]

\[ \sigma(\bar{\theta}, \bar{P}) = \bar{S} \quad \text{and} \quad \bar{S} \in \bar{N}. \]

**Footnote:** Here, in the case $\alpha = 0$, $L_0[A]$ is not technically a model, because its universe is empty, so we have to set $\text{Def}(\emptyset, \emptyset, \emptyset) = \emptyset$ to make literal sense of this definition.
that whenever $G \subseteq P$ is $P$-generic over $V$ with $p \in G$, there is in $V[G]$ a $\sigma' : N \prec N$ such that

1. $\sigma'(\bar{S}) = \sigma(\bar{S})$,
2. $(\sigma')^\ast G \subseteq G$,
3. $\sup \sigma^\ast \bar{\lambda}_i = \sup \sigma'^\ast \bar{\lambda}_i$ for each $i < n$.

$P$ is $\infty$-subcomplete iff the above holds with (3) removed.

I denote the classes of subcomplete and $\infty$-subcomplete forcing notions by SC and $\infty$-SC, respectively.

It should be pointed out that full models as in the previous definition are abundant. For example, suppose that $H_\theta \subseteq L[A]$, where $A \subseteq L_\beta[A]$, and let $\tau < \tau'$ be successive cardinals in $L[A]$, say, with $\beta < \tau$. Then whenever $X' \preceq L_\beta^A$ and $X = X' \cap L_\tau[A]$, it follows that $L_\beta^A | X$ is full.

The following easy fact can be used in order to further simplify the definitions of subcompleteness/$\infty$-subcompleteness.

**Fact 2.22.** Let $L_\tau^A$ be a model of ZFC$^-$, and let $s \in L_\tau[A]$. Then there is a $B$ such that $L_\tau[B] = L_\tau[A]$, $L_\beta^B \models$ ZFC$^-$ and such that $s$ is definable (without parameters) in $L_\beta^B$. Moreover, $B$ is definable in $L_\tau^A$ and $A \cap L_\tau[A]$ is definable in $L_\beta^B$. In particular, $L_\tau^A$ is full iff $L_\beta^B$ is.

**Proof.** First, by replacing $A$ with $A \cap L_\tau[A]$ if necessary, we may assume that $A \subseteq L_\tau[A]$. Second, we may assume that $A \subseteq \tau$. That is, we may construct a set $A' \subseteq \tau$ such that $L_\tau[A] = L_\tau[A']$, $A$ is definable in $L_\tau^A$ and $A'$ is definable in $L_\tau^A$. Namely, $L_\tau^A$ has a definable well-order of its universe, and since it is a model of ZFC$^-$, the monotone enumeration of $L_\tau[A]$ according to this well-order is definable in $L_\tau^A$, and its domain is $\tau$. Let’s call it $F : \tau \longrightarrow L_\tau[A]$. Let $R = \{(\alpha, \beta) \mid F(\alpha) \in F(\beta)\}$. Then $F$ is the Mostowski-collapse of the structure $\langle \tau, R \rangle$. Now it is easy to encode $R$ and $A$ as a set of ordinals, using Gödel pairs, for example, say

$A' = \{\langle 0, \alpha, \beta \rangle \mid F(\alpha) \in F(\beta)\} \cup \{\langle 1, \alpha \rangle \mid F(\alpha) \in A\}$.

Since $A'$ is a definable class in the ZFC$^-$-model $L_\tau^A$, it follows that $L_\tau^A = (L_\tau[A])^{L_\tau^A}$ is also a model of ZFC$^-$, and since $A'$ codes $F$, it follows that $L_\tau[A'] = L_\tau[A]$. Moreover, $A$ is definable in $L_\tau^A$, by design.

It is now easy to prove the fact: we can define $B = \{\langle 0, \alpha \rangle \mid \alpha \in A\} \cup \{\langle 1, \gamma \rangle\}$, where $s$ is the $\gamma$-th element of $L_\tau[A]$ in the canonical well-order. \qed

Of course, if any one element of $L_\tau[A]$ can be made definable by changing $A$ as in the previous fact, then any finitely many elements can be made definable by applying the same method to a finite sequence listing these elements. A consequence of this fact, or rather, its proof, is that in Definition 2.21, condition (1) is vacuous, because if $P$ satisfies this simplified definition, in the notation of that definition, one can modify $A$ to $A'$ in such a way that the desired parameters in $\bar{S}$ become definable in $\bar{N} = L_\tau^A$. Letting $\bar{N} = L_\tau^A$, and $\bar{N}' = L_\tau^A$ (where $A' = \sigma^{-1}A$ is constructed from $A$ the same way that $A'$ is constructed from $A$), it then follows that $\bar{N}'$ is full and $\sigma : \bar{N}' \prec \bar{N}'$. Thus, since $P$ satisfies the simplified version of subcompleteness, there is a condition in $P$ forcing the existence of an elementary embedding $\sigma' : \bar{N}' \prec \bar{N}'$ such that $\sigma'^\ast \bar{G} \subseteq \bar{G}$, where $\bar{G}$ is the canonical name for the generic filter. But then, $\sigma' : \bar{N} \prec \bar{N}$ as well, and $\sigma'$ must move the desired parameters the same way $\sigma$ did, since they/their preimages are definable in $\bar{N}'/\bar{N}'$. 

This means, in particular, that only condition (2) is really needed in the definition of \( \infty \)-subcompleteness.

The following definition is designed to capture the concept of \( \infty \)-SC-projective stationarity. If \( N \) is a model and \( X \) is a subset of \( |N| \), the universe of \( N \), then I write \( N|X \) for restriction of \( N \) to \( X \).

**Definition 2.23.** Let \( \kappa \) be an uncountable regular cardinal. A stationary set \( S \subseteq [H_\kappa]^\omega \) is spread out if for every sufficiently large cardinal \( \theta \), whenever \( \tau, A, X \) and \( a \) are such that \( H_\theta \subseteq L_\tau^A = N \models ZFC^- \), \( S, a, \theta \in X \), \( N|X \prec N \), and \( N|X \) is countable and full, then there are \( Y \) such that \( N|Y \prec N \) and an isomorphism \( \pi : N|X \rightarrow N|Y \) such that \( \pi(a) = a \) and \( Y \cap H_\kappa \in S \).

Using Fact 2.22 as before, one can see that the definition of being spread out can be simplified by dropping any reference to \( a \), since any desired parameter, or even any finite list of such parameters, can be made definable by modifying \( A \) while preserving fullness. So \( S \subseteq [H_\kappa]^\omega \) is spread out if for all sufficiently large \( \theta \), whenever \( H_\theta \subseteq L_\tau^A = N \models ZFC^- \), \( S \in X \), \( N|X \prec N \), and \( N|X \) is countable and full, then there is a \( Y \in S \) such that \( N|Y \cong N|X \prec N \).

Thus, in the situation of the previous definition, the stationarity of \( S \) guarantees the existence of some elementary submodel of \( N \) in \( S \uparrow \omega \), but if \( S \) is spread out, then every elementary submodel of \( N \) has an isomorphic copy in \( S \uparrow \omega \), as long as it is full.

The following theorem is the analog of Fact 2.10 for \( \infty \)-subcompleteness, providing a combinatorial characterization of \( \infty \)-SC-projective stationarity.

**Theorem 2.24.** Let \( \kappa \) be an uncountable regular cardinal, and let \( S \subseteq [H_\kappa]^\omega \). Then \( S \) is spread out if \( S \) is \( \infty \)-SC-projective stationary.

**Proof.** For the direction from left to right, suppose \( S \) is spread out. We have to show that \( \mathbb{P}_S \) is \( \infty \)-SC. To that end, let \( \theta \) be large enough for Definition 2.23 to apply. Let \( N = L_\omega^\theta \models ZFC^- \) with \( H_\theta \subseteq N \), and let \( \mathbb{P}_S \in X \), \( N|X \prec N \), \( X \) countable and full. Let \( a \) be some member of \( X \), and let \( \sigma : |N| \rightarrow X \) be the inverse of the Mostowski collapse of \( X \), \( |N| \) transitive, and \( \sigma : N \prec N \). Let \( \mathbb{P}_S = \mathcal{S}^{-1}(\mathbb{P}_S) \), \( \bar{a} = \sigma^{-1}(a) \), and let \( \bar{G} \subseteq \mathbb{P}_S \) be \( \bar{N} \)-generic. Note that since \( \mathbb{P}_S \in X \), \( S, H_\kappa \in X \).

Let \( \bar{\kappa} = \sigma^{-1}(\kappa) \). It follows from Fact 2.22 that \( \bar{U} \bar{G} \) is of the form \( \langle M_i \mid i < \omega_1^\bar{N} \rangle \) and \( \bigcup_{i < \omega_1^\bar{N}} M_i = H_{\bar{\kappa}}^{\bar{N}} \). Now, since \( S \) is spread out, let \( \pi : (X, \bar{\epsilon}) \rightarrow (Y, \bar{\epsilon}) \) be an isomorphism that fixes \( a, \mathbb{P}_S \), with \( Y \cap H_\kappa \in S \). Let \( \sigma' = \pi \circ \sigma : \bar{N} \prec Y \). Let \( q = \langle \sigma'(M_i) \mid i < \omega_1^\bar{N} \rangle \cap (Y \cap H_\kappa) \). Since \( Y \cap H_\kappa \in S \), it follows that \( q \in \mathbb{P}_S \), and whenever \( \bar{G} \supseteq q \) is \( \mathbb{P}_S \)-generic over \( V \), then \( \bar{\sigma}' \bar{G} \subseteq \bar{G} \). Since \( \bar{\sigma}'(\bar{a}) = a \), this shows that \( \mathbb{P}_S \) is \( \infty \)-subcomplete.

For the converse, suppose that \( S \) is \( \infty \)-SC-projective stationary, that is, that \( \mathbb{P}_S \) is \( \infty \)-subcomplete. Let \( \theta \) witness that \( \mathbb{P}_S \) is \( \infty \)-subcomplete. Let \( N = L_\omega^\theta \), \( X, a \) be as in Definition 2.23. Since \( S \in X \), it follows that \( \kappa, \mathbb{P}_S \in X \) as well. Let \( \sigma : \bar{N} \prec X \) be the inverse of the Mostowski collapse of \( X \). Thus, \( \sigma : \bar{N} \prec N \), and as usual, let \( \bar{a}, \bar{S}, \bar{\kappa}, \bar{\mathbb{P}}_S \) denote the preimages of \( a, \kappa, \mathbb{P}_S \) under \( \sigma \). Let \( \bar{G} \subseteq \bar{\mathbb{P}}_S \) be an arbitrary \( \bar{N} \)-generic filter. By \( \infty \)-subcompleteness of \( \mathbb{P}_S \), let \( p \in \mathbb{P}_S \) force the existence of an elementary embedding \( \sigma' : \bar{N} \rightarrow N \) with \( \sigma'(\bar{a}) = a \) and \( (\sigma')^\bar{G} = \bar{G} \) (\( G \) being the canonical \( \mathbb{P}_S \)-name for the generic filter). Since \( \mathbb{P}_S \) is countably distributive by Fact 2.4, it follows that there is such a \( \sigma' \in V \). Let \( Y = \text{ran}(\sigma') \), and let \( G \) be \( \mathbb{P}_S \)-generic over \( V \) with \( p \in G \). Let \( \delta = \omega_1^\bar{N} = \omega_1 \cap X \). As before, \( \bigcup \bar{G} \) is of the
form $\langle M_i \mid i < \delta \rangle$. By Fact 2.9 we have that $\bar{M}^* = \bigcup_{i < \delta} M_i = H^N_\delta$. For $i < \delta$, let $M_i = \sigma^*(M_i)$ - note that this is the same as $(\sigma')^* M_i$, as $M_i$ is countable in $N$. 
Since $G$ contains a condition of length $\delta + 1$, letting $M_\delta = \bigcup_{i < \delta} M_i$, the sequence $q = \langle M_i \mid i \leq \delta \rangle$ is in $G$. It follows that $M_\delta \subseteq S$. Moreover,
$$M_\delta = \bigcup_{i < \delta} \sigma^* M_i = \sigma^* \bar{M}^* = \sigma^* H^N_\delta = Y \cap H^N_\kappa$$
and so, $Y \cap H_\kappa \subseteq S$. Letting $\pi = \sigma' \circ \sigma^{-1}$, one sees that $\pi : X \rightarrow Y$ is an isomorphism that fixes $a$, thus verifying that $S$ is spread out. $\square$

Having a characterization of $\infty$-$SC$-projective stationarity of course gives a characterization of the $\infty$-$SC$-fragment of SRP.

**Theorem 2.25.** For an uncountable regular cardinal $\kappa$, the principle $\infty$-$SC$-SRP($\kappa$) holds iff every spread out subset of $[H_\kappa]^\omega$ contains a continuous $\in$-chain of length $\omega_1$.

It will often be useful to work with the following seemingly weaker form of the notion “spread out.” It will turn out to be equivalent, but it will sometimes be easier to verify.

**Definition 2.26.** Let $\kappa$ be an uncountable regular cardinal. A stationary set $S \subseteq [H_\kappa]^\omega$ is weakly spread out if there is a set $b$ such that for all sufficiently large $\theta$, the condition described in Definition 2.23 is true of all $X$ with $b \in X$.

**Observation 2.27.** Let $\kappa$ be an uncountable regular cardinal. A stationary set $S \subseteq [H_\kappa]^\omega$ is spread out iff it is weakly spread out.

**Proof.** Of course, if $S$ is spread out, it is also weakly spread out. For the converse, suppose $S$ is weakly spread out, as witnessed by the set $b$, say. Then the proof of Theorem 2.24 shows that $P_S$ satisfies the definition of $\infty$-subcompleteness, Definition 2.21 under the extra condition that $b \in \text{ran}(\sigma)$, in the notation of that definition. But this implies that $P_S$ is $\infty$-subcomplete, see the arguments in Jensen [33, P. 115f., in particular Lemma 2.5]. But if $P_S$ is $\infty$-subcomplete, then $S$ is spread out, by Theorem 2.24. $\square$

I would now like to make a few simple observations on the structure of the spread out sets and their relation to other notions of largeness of subsets of $[H_\kappa]^\omega$. First, of course, being spread out is a strengthening of projective stationarity.

**Observation 2.28.** If a stationary set $S \subseteq [H_\kappa]^\omega$ is spread out, then $S$ is projective stationary.

**Proof.** This is because $\infty$-$SC \subseteq SSP$. $\square$

In particular, spread out sets are stationary. In fact, being spread out is preserved by intersecting with a club; this is the analog of Fact 2.6.

**Observation 2.29.** Let $\kappa$ be an uncountable regular cardinal, let $S \subseteq [H_\kappa]^\omega$ be spread out, and let $C \subseteq [H_\kappa]^\omega$ be club. Then $S \cap C$ is spread out.

**Proof.** Let $f : H_\kappa^\omega \rightarrow H_\kappa$ be such that every $a \in H_\kappa$ closed under $f$ is in $C$. By Observation 2.27 it suffices to show that $S \cap C$ is weakly spread out. Thus, it will be enough to show that the condition described in Definition 2.23 is satisfied for all sufficiently large $\theta$, assuming that $f \in X$, using the notation in the definition.
Since $S$ is spread out, there is a $Y$ such that $Y \cap H_\kappa$ in $S$ and such that there is an isomorphism $\pi : (X, \in \cap X^2) \rightarrow (Y, \in \cap Y^2)$ that fixes a given $a$, and also $f$, that is, $\pi(f(a)) = (f, a)$. Since $f \in Y$, it follows that $Y$ is closed under $f$, and hence that $Y \cap H_\kappa \subseteq S \cap C$. 

Thus, $\infty$-$\text{SC-SRP}$ guarantees the existence of elementary chains through spread out sets. Thirdly, being spread out is preserved by projections, analogous to the situation with stationarity and projective stationarity.

Observation 2.30. Let $A \subseteq B \subseteq C$, and let $S \subseteq [B]^\omega$ be spread out, with $\bigcup S = B$. Then:

1. $S \uparrow C$ is spread out.
2. $S \downarrow A$ is spread out.

Proof. We prove (1) and (2) simultaneously. Let $\theta$ be sufficiently large, and let $X \prec N = L^\theta \models \text{ZFC}^-$ be countable and full, with $S, a, C \in N$ (as usual, we may require some additional parameter to be in $X$). Since $S$ is spread out, there are a $Y$ with $N|Y \prec N$ and an isomorphism $\pi : N|X \rightarrow N|Y$ that fixes $a$, and such that $Y \cap B \subseteq S$. But this means that $Y \cap C \subseteq S \uparrow C$ and that $Y \cap A \subseteq S \downarrow A$, as wished. 

Observation 2.31. If $S \subseteq [H_\kappa]^\omega$ contains a club, then $S$ is spread out.

Proof. Let $f : [H_\kappa]^\omega \rightarrow H_\kappa$ be such that every $x \in C$ is closed under $f$, that is, $f^\omega[x]^\omega \subseteq x$. Let $\theta$ be sufficiently large that $[H_\kappa]^\omega \in \text{H}_\theta$. I claim that this $\theta$, together with the function $f$, witnesses that $S$ is weakly spread out, which implies that $S$ is spread out by Observation 2.27. To see this, suppose $H_\theta \subseteq L^\theta \models \text{ZFC}^-$ and $S, f \in L^\theta[A]$. Let $X \subseteq L^\theta[A]$ be countable, $N|X \prec L^\theta[A]$, and $f \in X$ (and $N|X$ is full). Since $f \in X$, $X$ is closed under $f$, and hence, so is $X \cap H_\kappa$. Thus, $X \cap H_\kappa \subseteq S$ (so we can choose $Y = X$ in the notation of Definition 2.21). 

Finally, an elementary argument shows that in the situation of Definition 2.21 necessarily, $\sigma'(2^\omega)^N = \tau'(2^\omega)^N$, see 21, Obs. 4.2, or 18, Proof of Lemma 3.22]. That argument, adapted to the present context, has the following consequence. Notice the parallel to Example 2.10.

Observation 2.32. Let $\kappa \leq 2^\omega$ be an uncountable regular cardinal, and let $S \subseteq [H_\kappa]^\omega$. Then $S$ is spread out iff $S$ contains a club. Hence, $\infty$-$\text{SC-SRP}(\kappa)$ holds trivially.

Proof. Suppose $S \subseteq [H_\kappa]^\omega$ is spread out. Let $\theta$ be sufficiently large, and let $N = L^\theta \models \text{ZFC}^-$ with $H_\theta \subseteq L^\theta[A]$, and suppose $\tau$ is an $L[A]$-cardinal. Let $\tau' = (\tau^+)^L[A]$. Let $N' = L^\theta[A]$. It is then easy to see that whenever $X$ is countable and $N'|X \prec N'$, then, letting $\bar{X} = X \cap L^\theta[A]$, $N|\bar{X} \prec N$ and $N|\bar{X}$ is full. Now let

$C = \{X \in [L^\omega] : N|X \prec N\}$.

I claim that $\bar{C} = C \downarrow [H_\kappa]^\omega \subseteq S$. To see this, let $X \in \bar{C}$. Then $X = Y \cap H_\kappa$, for some $Y \in C$. Let $Y = Y \cap L^\theta[A]$, so $N|Y \prec N$ is full. Since $S$ is spread out, there is a $Z$ such that $N|Z \prec N$ so that $N|Y$ is isomorphic to $N|Z$ and $Z \cap H_\kappa \subseteq S$. Let $\pi : N|Y \rightarrow N|Z$ be this isomorphism. First, observe that $\pi|2^\omega = \text{id}$. To see this, first note that $\pi|P(\omega) = \text{id}$, and hence that $P(\omega) \cap Y = P(\omega) \cap Z$. Let $f$ be the $<_L\lambda$-least bijection between $P(\omega)$ and $2^\omega$. Clearly, $f \in Y \cap Z$, and $\pi(f) = f$. It
follows that $\pi|2^\omega = \text{id}$ and hence that $2^\omega \cap Y = 2^\omega \cap Z$, because if $\alpha < 2^\omega$ and $\alpha \in Y$, then letting $a = f^{-1}(\alpha)$, we have that $\pi(\alpha) = \pi(f(a)) = \pi(f)(\pi(a)) = f(a) = \alpha$. But then, it follows that $\pi|H_{2^\omega} = \text{id}$, and hence that $H_{2^\omega} \cap Y = H_{2^\omega} \cap Z$. This is because if $a \in H_{2^\omega} \cap X$, then $a$ can be coded by a bounded subset $A$ of $2^\omega$. Then $\pi(A) = A$ codes the same object, and so, $\pi(a)$ is the set coded by $\pi(A) = A$, which is $a$. In particular, $X = Y \cap H_\kappa = Z \cap H_\kappa \in S$. Thus, $C = C \downarrow \langle H_\kappa \rangle^\omega \subseteq S$, as claimed. Since $C$ is a club, $C \downarrow \langle H_\kappa \rangle^\omega$ contains a club, as wished.

The converse is trivial, by Observation 2.31.

This proves the equivalence claimed, and of course, it is easy to construct an continuous $\in$-chain of length $\omega_1$ through $S$ if $S$ contains a club, so that $\infty$-$\text{SC-SRP}(\kappa)$ holds.

In ending this section, for completeness, let me mention an obvious modification to the concept of being spread out that corresponds to subcomplete (not subsubcomplete) projective stationarity, as follows.

**Definition 2.33.** Let $\kappa$ be an uncountable regular cardinal. A stationary set $S \subseteq [H_\kappa]^{\omega}$ is fully spread out if for all sufficiently large $\theta$, whenever $\pi$, $A$ are such that $H_\theta \subseteq L^A \models \text{ZFC}$, $S, \theta \in X \prec L^A$ is countable and full, if $a \in X$, $\lambda_0, \ldots, \lambda_n$ are such that $\lambda_n = \sup(X \cap \text{On})$ and for every $i < n$, $\lambda_i$ is a regular cardinal in the interval $(2^{2^{\lambda_{i-1}}}, \lambda_n)$, then there exist $\pi$, $Y$ such that $N|Y \prec N$ and $\pi : (X, \in \cap X^2) \rightarrow (Y, \in \cap Y^2)$ is an isomorphism such that $\pi(a) = a$ and for $i \leq n$, $\sup(X \cap \lambda_i) = \sup(Y \cap \lambda_i)$, and $Y \cap H_\kappa \in S$.

A repeat of the proof of Theorem 2.24 shows that being fully spread captures subcomplete projective stationarity:

**Theorem 2.34.** Let $\kappa$ be an uncountable regular cardinal, and let $S \subseteq [H_\kappa]^{\omega}$. Then $S$ is fully spread out iff $S$ is $\text{SC}$-projective stationary.

From here on out, to make things slightly less technical, I will for the most part focus on spread out sets. Everything I do would also go through for fully spread out sets, unless I explicitly say otherwise.

### 3. Consequences

In order to carry over consequences of $\text{SRP}$ to its subcomplete fragment, I will need to know that certain sets are not only projective stationary, but in fact spread out. Proving that a set is spread out is generally not an easy task, but fortunately, all I need will follow from one technical lemma, which I will prove in the following subsection. In later subsections, I will use this in order to derive consequences concerning Friedman’s problem, the failure of square, the singular cardinal hypothesis and mutual stationarity.

#### 3.1. Barwise theory and a technical lemma

The proof of the main technical, but very useful lemma will employ methods of Barwise, so I will summarize what I will need very briefly. I follow Jensen’s excellent presentation of this material in [33, p. 102 ff]. For a more detailed treatment, see Barwise [4], or Jensen’s set of handwritten notes [32].

Recall that a structure $(M, A_1, \ldots, A_n)$ is admissible if it is transitive and satisfies $\text{KP}$ (which I take to include the axiom of infinity), using the predicates $A_1, \ldots, A_n$. 

For admissible $M$, Barwise developed an infinitary logic where the infinitary formulas are (coded by) elements of $M$. Thus, infinitary conjunctions and disjunctions are allowed, as long as they are in $M$, but only finite strings of quantifiers may occur, and all predicate symbols are finitary. Let $A$ be a $\Sigma_1(M)$ set of such infinitary formulas. Thus, the set of formulas $A$ itself can be defined by a finitary first order formula over $M$ that is $\Sigma_1$. The set $A$ may well contain formulas that are not $\Sigma_1$, so it is not a $\Sigma_1$-theory in the usual model theoretic sense. The intuition is that elements of $M$ behave like finite sets in finitary logic (and hence, they are called “$M$-finite”), and $\Sigma_1(M)$ sets behave like recursively enumerable ones. The logic comes with a proof theory and a model theory whose main features are:

1. **The $M$-finiteness lemma**: if a formula $\varphi$ is provable from $A$, then there is an $u \in M$ such that $u \subseteq A$ and $\varphi$ is provable from $u$.

2. **The correctness theorem**: if there is a model $\mathfrak{A}$ with $\mathfrak{A} \models A$, then $A$ is consistent.

3. **The Barwise completeness theorem**: if $M$ is countable and $A$ is consistent, then there is a model $\mathfrak{A}$ with $\mathfrak{A} \models A$.

**Definition 3.1.** Let $M$ be admissible. If $A$ consists of infinitary formulas in $M$, then $A$ is a *theory on $M$*. $A$ is an $\in$-theory on $M$ if the language it is formulated in contains the symbol $\in$, a constant symbol $\underline{x}$, for every $x \in M$, and if the theory contains the extensionality axiom, as well as the *basic axiom*

$$\forall y \ (y \in \underline{x} \iff \bigvee_{z \in x} y = z)$$

for every $x \in M$. It is a $\text{ZFC}^-$-theory on $M$ if it is an $\in$-theory on $M$ that contains the $\text{ZFC}^-$ axioms (viewed as a set of finitary formulas, which are also in $M$).

If $A$ is an $\in$-theory on $M$ and $\mathfrak{A}$ is a model for $A$ whose well-founded part is transitive, then automatically, $\underline{x}^\mathfrak{A} = x$, which is why I won’t specify the interpretation of these constants by such a model. The following property is a slight weakening of fullness, see Definition \[2.19\].

**Definition 3.2.** A transitive model $N$ of $\text{ZFC}^-$ is *almost full* if there is a model $\mathfrak{A}$ of $\text{ZFC}^-$ whose well-founded part is transitive, $N$ is an element of the well-founded part of $\mathfrak{A}$ and $N$ is regular in $\mathfrak{A}$, i.e., if $x \in N$, $f \in \mathfrak{A}$, and $f : x \rightarrow N$, then $\text{ran}(f) \subseteq N$.

The same comments made after Definition \[2.19\] apply here as well. In applications, the model $N$ will be of the form $L^\mathfrak{A}_\alpha$, so that no complications arise.

**Definition 3.3.** If $N$ is a transitive set, then I write $\alpha(N)$ for the least $\alpha > 0$ such that $L_\alpha(N) \models \text{KP}$.

The next lemma will be used crucially in the proof of Lemma \[3.5\].

**Transfer Lemma 3.4** ([33] p. 123, Lemma 4.5]). Let $\bar{N}$ and $N$ be transitive $\text{ZFC}^-$-models. Let $\bar{N}$ be almost full and $\sigma : \bar{N} \rightarrow \Sigma_0 N$ be cofinal, that is, $N = \bigcup \text{ran}(\sigma)$. Then $N$ is almost full. Further, let $\bar{L}$ be a theory in an infinitary language on $L_{\alpha(\bar{N})}(N)$ that has a $\Sigma_1$-definition in $L_{\alpha(\bar{N})}(\bar{N})$ in the parameters $\bar{N}$ and $p_1, \ldots, p_n \in \bar{N}$. Let $L$ be the infinitary theory on $L_{\alpha(N)}(N)$ defined over $L_{\alpha(N)}(N)$ by the same $\Sigma_1$-formula, using the parameters $N$, $\sigma(p_1), \ldots, \sigma(p_n)$. If $\bar{L}$ is consistent, then so is $L$. I will denote $L$ by $\sigma(L)$. 
Coming up is the technical lemma I need, a general version of Jensen’s Lemma 6.3. The present lemma differs from Jensen’s version in several respects.

First, the formulation is different. Jensen’s lemma states that if $\kappa > \omega_1$ is regular and $A \subseteq \kappa$ is a stationary set consisting of ordinals of countable cofinality, then the usual forcing to shoot a club through $A$ with countable conditions is subcomplete. The present version of the lemma implies this, under the additional assumption that $\kappa > 2^\omega$.

More importantly, the original lemma assumes that $\kappa > \omega_1$, while I need $\kappa > 2^\omega$. It was first observed by Sean Cox that there is a step in Jensen’s proof that seems to only go through if $\kappa > 2^\omega$, and I thank him sincerely for pointing this out to me. The assumption is actually needed for the lemma, as I observe in the note following the statement of the lemma, and it is also needed for the original lemma, as was originally noticed by Hiroshi Sakai (as communicated by Corey Switzer). The assumption is used in Claim (5) of the proof.

On the other hand, while Jensen’s lemma was missing a needed assumption, the its proof made an assumption that is not needed, namely that $A$ belongs to the range of the embedding $\sigma$. It will play a role later on, in Lemma 3.29, that this is unnecessary. In fact, the present version of the lemma does not mention $A$.

In the article containing the original lemma, Jensen works with a variant of sub-completeness [33, Def. on p. 114] in which the “suprema condition” (3) of Definition 2.21 is replaced with a “hull condition” which implies the suprema condition. Accordingly, the proof of his lemma establishes a potentially stronger property than (b) and (e). But the proof of the present version of the lemma establishes that condition as well, as I point out in Remark 3.6 after the proof.

Finally, Jensen’s lemma does not mention clause (c), and this clause will also be important in the aforementioned application.

I will carry the proof out in considerable detail, because it is a subtle argument in which it is easy to overlook problems (and this has happened in the past, as I explained).

**Lemma 3.5.** Let $\kappa > 2^\omega$ be a regular cardinal, $\theta > 2^{2^\omega}$ regular, $N$ a transitive model of $\text{ZFC}^-$ (in a finite language) with a definable well-ordering of its universe and $H_\theta \subseteq N$, $\sigma : \bar{N} \prec N$, where $\bar{N}$ is countable and full and $\kappa \in \text{ran}(\sigma)$. Let $\eta \in \kappa \cap \text{ran}(\sigma)$ be such that $\eta^\sigma < \kappa$. Let $\bar{\kappa}, \bar{\eta}$ be the preimages of $\kappa, \eta$ under $\sigma$, respectively. Let $\langle \bar{\lambda}_i \mid i < n \rangle$ be regular cardinals in $\bar{N}$, each greater than $\bar{\kappa}$. Let $\bar{a}$ be some element of $\bar{N}$.

Then there is an $\omega$-club of ordinals $\kappa_0 < \kappa$ (i.e., the set of such $\kappa_0$ is unbounded in $\kappa$ and closed under limits of countable cofinality) for which there is an embedding $\sigma' : \bar{N} \prec N$ with the following properties:

1. Letting $p = \{ \bar{a}, \bar{\kappa}, \bar{\eta}, \bar{\lambda}_0, \ldots, \bar{\lambda}_{n-1} \}$, we have that $\sigma|p = \sigma'|p$.
2. For $i < n$, $\sup \sigma"^\omega \lambda_i = \sup \sigma'"^\omega \bar{\lambda}_i$.
3. $\sigma|\bar{\eta} = \sigma'|\bar{\eta}$.
4. $\sup \sigma'"^\omega \bar{\kappa} = \kappa_0$.
5. $\sup \sigma"^\omega (\text{On} \cap \bar{N}) = \sup \sigma'"^\omega (\text{On} \cap N)$.

**Note:**
(1) Instead of a single $\vec{a}$, one can choose finitely many members of $\vec{N}$, say $\vec{a}_0, \ldots, \vec{a}_{n-1}$, and find a $\sigma'$ as in the lemma that moves each of these elements the same way $\sigma$ does, because one can apply the lemma to the sequence $\langle \vec{a}_0, \ldots, \vec{a}_{n-1} \rangle$.

(2) The assumption that $\kappa > 2^\omega$ is necessary, because if $\sigma' : \vec{N} \prec N$, then $\sigma'((2^\omega)^N) = \sigma((2^\omega)^N)$. Clearly, $\sigma((2^\omega)^N) = 2^\omega = \sigma'((2^\omega)^N)$. And if $f$ is the $N$-least bijection from $\mathcal{P}(\omega)$ to $2^\omega$, and $\bar{f}$ is the $\vec{N}$-least bijection from $(\mathcal{P}(\omega))^N$ to $(2^\omega)^N$, then $\sigma(\bar{f}) = f = \sigma'$. It follows that for any ordinal $\xi < (2^\omega)^N$, letting $x = \bar{f}^{-1}(\xi)$, then $\sigma(\xi) = \sigma(\bar{f}(x)) = \sigma'((\bar{f}(x)) = \sigma'(\xi)$.

Proof. Let me define $\sigma = \sigma(\vec{a}), \lambda_i = \sigma(\lambda_i)$, for $i < n$, and $\eta = \sigma(\vec{\eta})$.

Since $N$ has a definable well-order of its universe, for every subset $X$ of the universe of $N$, there is a minimal (with respect to inclusion) subset $Y$ of the universe of $N$ that contains $X$ such that $N \upharpoonright Y \prec N$. I denote this $Y$ by $\text{Hull}(N,X)$, and I will use this notation for other models that have a definable well-order as well. Clearly, the set

$$C = \{ \alpha < \kappa \mid \text{Hull}^N(\alpha \cup \text{ran}(\sigma)) \cap \kappa = \alpha \}$$

is club in $\kappa$. I claim that whenever $\alpha \in C$ has countable cofinality, then there is a $\sigma'$ as described, proving the lemma.

For the purpose of the proof, let me define that for transitive models $M$ and $\bar{M}$ of $\text{ZFC}^-$, an embedding $j : M \prec \bar{M}$ is cofinal if for every $x \in M$ there is a $\eta \in \bar{M}$ such that $x \in j(\eta)$. If $\bar{\delta}$ is a cardinal in $\bar{M}$, then $j : M \prec \bar{M}$ is $\bar{\delta}$-cofinal if for every $x \in M$ there is a $\eta \in \bar{M}$ of $M$-cardinality less than $\bar{\delta}$ with $x \in j(\eta)$. I will use the following facts several times throughout the proof.

(A) If $j : M \prec M$, $\bar{\delta} = j(\bar{\delta})$ and $M = \text{Hull}^M(\text{ran}(j) \cup \delta)$, then $j$ is $\bar{\delta}^+$-cofinal.

(B) If $j : M \prec M$ is $\bar{\delta}$-cofinal, then $j$ is continuous at every $\bar{\lambda} \in M$ with $\text{cf}^M(\bar{\lambda}) \geq \bar{\delta}$, that is, $j(\bar{\lambda}) = \sup_j \bar{\lambda}$.

Proof of [(A) $\&$ (B)]. To see [(A)] let $x \in M$ be given. By assumption, $x$ is definable in $M$ from some ordinal $\alpha < \bar{\delta}$ and some elements $a_0, \ldots, a_{n-1}$ of $\text{ran}(j)$. Let’s say $x$ is the unique $z$ such that $M \models \varphi(z, \alpha, \vec{a})$. Let $\vec{a}_0, \ldots, \vec{a}_{n-1}$ be the preimages of $a_0, \ldots, a_{n-1}$ under $j$, and consider the function $\bar{f} : \bar{\delta} \to M$ defined in $M$ by letting $\bar{f}(\vec{a})$ be the unique $z$ such that $\varphi(z, \vec{a}, \vec{a})$ holds, if such a $z$ exists, and let $\bar{f}(\vec{a}) = 0$ otherwise. Clearly, if we set $y = \text{ran}(\bar{f})$, then $x \in j(y)$, and $y$ has $M$-cardinality at most $\bar{\delta}$.

To see [(B)] fix a $\bar{\lambda}$ as stated. To show that $j(\bar{\lambda}) = \sup_j \bar{\lambda}$, note that the right hand side is obviously less than or equal to the left hand side. For the converse, suppose $\alpha < j(\bar{\lambda})$. By $\bar{\delta}$-cofinality, let $y \in \bar{N}$ have $\bar{N}$-cardinality less than $\bar{\delta}$, with $\alpha \in j(y)$. We may assume that $y \subseteq \bar{\lambda}$ (by intersecting it with $\bar{\lambda}$ if necessary). But then $y$ is bounded in $\bar{\lambda}$, since the $\bar{N}$-cofinality of $\bar{\lambda}$ is at least $\bar{\delta}$, say $y$ is bounded by $\xi < \bar{\lambda}$. Then $\alpha \in j(y) \subseteq j(\xi) \subseteq \sup_j \bar{\lambda}$. \hfill \Box

Now, let me fix $\kappa_0 \in C$ with $\text{cf}(\kappa_0) = \omega$, let $N_0$ be the transitive collapse of $\text{Hull}^N(\kappa_0 \cup \text{ran}(\sigma))$, and let $k_0$ be the inverse of the collapse. We have:

$$k_0 : N_0 \prec N, \text{crit}(k_0) = \kappa_0, k_0(\kappa_0) = \kappa.$$

Note that since $\eta, 2^\omega \in \text{ran}(\sigma) \cap \kappa$, it follows that $\kappa_0 > \eta, 2^\omega$. 

Since \( \text{ran}(\sigma) \subseteq \text{ran}(k_0) \), there is an elementary embedding
\[
\sigma_0 : \bar{N} \prec N_0
\]
defined by \( \sigma_0 = k_0^{-1} \circ \sigma \). Then we have
- \( \sigma_0 : \bar{N} \prec N_0 \),
- \( \sigma_0(\bar{k}) = \kappa_0 \),
- \( k_0 \circ \sigma_0 = \sigma \).

Let me define \( a_0 = \sigma_0(\bar{a}) \), \( \eta_0 = \sigma_0(\bar{\eta}) \) and \( \lambda_{i,0} = \sigma_0(\bar{\lambda}_i) \), for \( i < n \).

By [A] it follows that
1. \( \sigma_0 : \bar{N} \prec N_0 \) is a \((\bar{k}^+)^\bar{N}\)-cofinal embedding.

Figure [1] on the right summarizes the situation so far. The circles indicate the cofinal image, that is, the function \( \alpha \mapsto \sup f^\alpha \). An arrow with superimposed circles indicates that the function at hand is continuous at this point, that is, that the point is mapped to its cofinal image by the function.

Next, I will define an intermediate model in between \( \bar{N} \) and \( N_0 \). The construction is similar to forming an extender ultrapower of \( \bar{N} \) by an extender derived from \( \sigma_0|\bar{k} \).

More precisely, \( N_1 \) is the Mostowski collapse of the set
\[
H = \{ \sigma_0(\bar{f})(\alpha) \mid \exists \beta < \bar{k} \: \bar{f} : \beta \to \bar{N}, \: \bar{f} \in \bar{N}, \: \alpha < \sigma_0(\beta) \}
\]
and, letting \( k_1 \) be the inverse of the collapsing isomorphism, \( \sigma_1 = k_1^{-1} \circ \sigma_0 \). It is not hard to check that \( H \prec N_0 \), so that this makes sense. Then:
\[
\sigma_1 : \bar{N} \prec N_1, \: k_1 : N_1 \prec N_0, \: \sigma_0 = k_0 \circ \sigma_1.
\]
Let me set \( a_1 = \sigma_1(\bar{a}) \), \( \eta_1 = \sigma_1(\bar{\eta}) \), \( \kappa_1 = \sigma_1(\bar{\kappa}) \) and \( \lambda_{i,1} = \sigma_1(\bar{\lambda}_i) \), for \( i < n \). The situation is illustrated in Figure [2]

It is easy to see from the definition of \( N_1 \) that
2. \( \sigma_1 : \bar{N} \prec N_1 \) is \( \bar{k} \)-cofinal.

Namely, given \( y \in N_1 \), it follows that \( k_1(y) \) is of the form \( \sigma_0(\bar{f})(\alpha) \), for some function \( \bar{f} : \beta \to \bar{N} \) in \( \bar{N} \), where \( \beta < \bar{k} \) and \( \alpha < \sigma_0(\beta) \). Thus, letting \( x = \text{ran}(\bar{f}) \), we have that \( x \) has cardinality less than \( \bar{k} \) in \( \bar{N} \), and \( k_1(y) \in \sigma_0(x) = k_1(\sigma_1(x)) \), and so, pulling back via \( k_1^{-1} \), we have that \( y \in \sigma_1(x) \).

By [B] we have:
3. For any \( \bar{\lambda} \in \bar{N} \) of \( \bar{N} \)-cofinality at least \( \bar{k} \), it follows that \( \sup \sigma_1\bar{\lambda} = \sigma_1(\bar{\lambda}) \).

It is also clear that
4. \( k_1|\kappa_1 = \text{id} \). As a result, \( \sigma_1|\bar{k} = \sigma_0|\bar{k} \).
This is because $\kappa_1 \subseteq H$: suppose $\alpha < \kappa_1$. Then by (3) $\alpha < \sigma_1(\kappa) = \sup \sigma_1^{\kappa^+}$. So let $\beta < \kappa$ be such that $\alpha < \sigma_1(\beta) \leq \sigma_0(\beta)$. Then $\alpha = \sigma_0(\text{id}|\beta)(\alpha) \in H$.

The next step in the proof is crucial. It is where the assumption that $\kappa > 2^\omega$ is used, and it is the verification of the next claim that is missing in Jensen’s Lemma 6.3.

(5) $\bar{N} \in N_1$.

To see this, let us view $\bar{N}$ as a subset of $\omega$ temporarily; it can easily be coded that way. Note that by elementarity, $\mathcal{P}(\omega) \subseteq \bar{N}$, and also $\mathcal{P}(\omega) \cap N_0$. The cardinality of $\mathcal{P}(\omega)$ is $2^\omega$, which is less than $\kappa$, by assumption. Thus, since $\kappa_0 \in C$, $2^\omega < \kappa_0$ as well. Since $\text{crit}(k_0) = \kappa_0$, it follows that $(2^\omega)^{N_0} = 2^\omega$. By elementarity, there is in $N_0$ a bijection $g: 2^\omega \rightarrow \mathcal{P}(\omega)$. Since $\text{crit}(k_0) = \kappa_0 > 2^\omega$, it follows that $k_0(g) = g$, and hence that $g$ is actually a bijection between $2^\omega$ and $\mathcal{P}(\omega)$. Thus, $\mathcal{P}(\omega) \subseteq N_0$, since $2^\omega \subseteq \kappa_0 \subseteq N_0$. Moreover, $\mathcal{P}(\omega) \subseteq H$. This is because if we let $\bar{c} = (2^\omega)^{\bar{N}}$, then $\bar{c} < \kappa$, and so, letting $\bar{g}: \bar{c} \rightarrow \mathcal{P}(\omega)^{\bar{N}}$ be a bijection, it follows that $\sigma_0(\bar{g}) : \sigma_0(\bar{c}) \rightarrow \mathcal{P}(\omega)$ is a bijection and for every $\xi < \sigma_0(\bar{c})$, $\sigma_0(\bar{g})(\xi) \in H$. Every subset of $\omega$ is of this form. Thus, $\bar{N} \in H$, and so, $\bar{N} = k_1^{-1}(\bar{N}) \in N_1$.

Notice that clause (c) of the lemma can be equivalently expressed as $\sigma^\kappa \eta = \sigma^\kappa \bar{\eta}$. This is why the following point will be relevant.

(6) $\sigma_0^{\kappa_0} \eta = \sigma_1^{\kappa_0} \bar{\eta} \in N_1$.

The reasoning is much like the argument for the previous claim. First, though, since $k_1|\kappa_1 = \text{id}$, it follows that $\sigma_0^{\kappa_0} \eta = \sigma_1^{\kappa_0} \bar{\eta}$, as $\bar{\eta} < \bar{\kappa}$, and it also follows that $\eta = \eta_0 = \eta_1$, since $\kappa_1 \leq k_0(\kappa_1) = \kappa_0$ and $k_0|\kappa_0 = \text{id}$.

Clearly, $\eta < \kappa_0$, and since $\eta_\omega < \kappa$, it also follows that $\eta_\omega < \kappa_0$, as $\kappa_0 \in C$. It follows as before that $[\eta]_\omega \subseteq \text{Hull}^N(\text{ran}(\sigma) \cup \kappa_0)$, and since $\text{crit}(k_0) = \kappa_0$, it follows that $[\eta]_\omega \subseteq N_0$. Further, since in $\bar{N}$, $\bar{\eta} < \bar{\kappa}$, it follows as before that $[\bar{\eta}]_\omega \subseteq H$. Hence, $k_1^{-1}[\eta]_\omega = [\eta]_\omega \subseteq N_1$. In particular, $\sigma_1^{\kappa_0} \bar{\eta} \in N_1$.

Now let $\alpha(N_1)$ be the least $\beta > 0$ such that $L_\beta(N_1)$ is admissible, and let $N^+_1 = L_\alpha(N_1)(N_1)$. By Claims (5) and (6) $\bar{N}$ and $\sigma_0^{\kappa_0} \eta$ are elements of $N_1$, which allows us to define the $\mathbf{ZFC}^-$-theory $L_1$ on $N^+_1$ that has an extra constant symbol $\bar{\sigma}$ and the following additional axioms:

- $\bar{\sigma}: \bar{N} \prec N^+_1 \bar{\kappa}$-cofinally.
what the axioms in $\hat{\mathcal{A}}$ make sense.

Since $k_1 \circ \sigma_1 : \hat{N} \prec N_0$ is cofinal, by Claim [1] it follows that $k_1 : N_1 \prec N_0$ is cofinal as well, and hence, we know by the Transfer Lemma 3.4 which is applicable since $\hat{N}$ is full, that the theory $\mathcal{L}_0 = "k_1(\mathcal{L})"$ on $N_0^+=L_{\alpha(N_0)}(N_0)$ is also consistent. In more detail, $\mathcal{L}_0$ is the ZFC$^-$-theory on $N_0^+$ with the extra constant symbol $\hat{\sigma}$ and the additional axioms

\begin{itemize}
  \item $\hat{\sigma} : \hat{N} \prec N_0$ $\hat{\kappa}$-cofinally.
  \item $\hat{\sigma}(\hat{k}, \hat{\alpha}, \hat{\eta}, \hat{\lambda}_0, \ldots, \hat{\lambda}_{n-1}) = \kappa_0, \alpha_0, \eta_0, \lambda_0, \ldots, \lambda_{n-1}$.
  \item $\hat{\sigma}^{\hat{\lambda}} = \sigma_0^{\lambda} \hat{\eta}$.
\end{itemize}

Notice here that $k_1(\hat{N}) = \hat{N}$, since by elementarity, $N_1$ sees that $\hat{N}$ is coded by a real, and that real is not moved by $k_1$. And $k_1(\sigma_1^{\hat{\eta}}) = \sigma_1^{\hat{\eta}} = \sigma_0^{\lambda} \hat{\eta}$ since $k_1|k_1 = \text{id}$ and $k_1 > \sigma_1(\hat{\eta}) = \eta$.

In the last step of the proof, I would like to use Barwise completeness, ideally to find an elementary embedding as described in $\mathcal{L}_0$. But Barwise completeness only applies to countable theories, so the idea is to put all the relevant information inside a sufficiently rich model, and take a countable elementary substructure. Thus, let $M = (H_k, \in, N_0, \kappa_0, \sigma_0, a_0, \eta_0, \lambda_0)$. Let $\pi : M \prec M$ be such that $M$ is countable and transitive. Note that $\hat{N}$ is definable from $\sigma_0$ and $N_0$, and so are $\hat{\kappa}, \hat{\eta}$ and $\hat{\lambda}$, and so, all of these objects are in the range of $\pi$. Note further that $\pi^{-1}(\hat{N}) = \hat{N}$, since $\hat{N}$ is coded by a real number in $M$, and moreover, $\pi|\hat{N} = \text{id}$. I will write $\hat{x}$ for $\pi^{-1}(x)$ when $x \in \text{ran}(\pi)$. So $\sigma_0 : \hat{N} \prec N_0$, and it follows that $\sigma_0 = \pi \circ \sigma_0$, because for $x \in \hat{N}$, $\sigma_0(x) = \pi(\sigma_0)(x) = \pi(\sigma_0)(\pi(x)) = \pi(\sigma_0(x))$.

Clearly, $\mathcal{L}_0$ is definable in $M$, and hence in the range of $\pi$. Its preimage is $\hat{\mathcal{L}}_0 = \pi^{-1}(\mathcal{L}_0)$. $\hat{\mathcal{L}}_0$ is then a consistent language on the structure $\hat{N}^+ = \pi^{-1}(N_0^+)$. Since this structure is countable (in $\mathbb{V}$), it has a model, say $\mathcal{A}$, whose well-founded part may be chosen to be transitive. Let $\hat{\sigma}' = \hat{\sigma}^\lambda$. Note that we do not know that $\hat{\sigma}' \in M$. Set

$$\sigma' = k_0 \circ \pi \circ \hat{\sigma}'$$

I claim that $\sigma'$ has the desired properties. To see this, it will be useful to write out what the axioms in $\hat{\mathcal{L}}$ express:

\begin{itemize}
  \item the basic axioms and ZFC$^-$.
  \item $\hat{\sigma} : \hat{N} \prec N_0$ $\hat{\kappa}$-cofinally.
  \item $\hat{\sigma}(\hat{k}, \hat{\alpha}, \hat{\eta}, \hat{\lambda}_0, \ldots, \hat{\lambda}_{n-1}) = \kappa_0, \alpha_0, \eta_0, \lambda_0, \ldots, \lambda_{n-1}$.
  \item $\hat{\sigma}^{\hat{\lambda}} = \sigma_0^{\lambda} \hat{\eta}$.
\end{itemize}

Since $\mathcal{A}$ is a model of this theory, we have that

\begin{itemize}
  \item $\hat{\sigma}' : \hat{N} \prec \hat{N}_0$ is $\hat{\kappa}$-cofinal,
  \item $\hat{\sigma}'(\hat{k}, \hat{\alpha}, \hat{\eta}, \hat{\lambda}_0, \ldots, \hat{\lambda}_{n-1}) = \hat{k}_0, \hat{\alpha}_0, \hat{\eta}_0, \hat{\lambda}_0, \ldots, \hat{\lambda}_{n-1}$, and
  \item $(\hat{\sigma}')^{\hat{\lambda}} = \sigma_0^{\lambda} \hat{\eta}$.
\end{itemize}

Composing with $\pi$, and writing $\hat{\sigma} = \pi \circ \hat{\sigma}'$, this translates to:

\begin{itemize}
  \item $\sigma : \hat{N} \prec N_0$,
  \item $\sigma(\hat{k}, \hat{\alpha}, \hat{\eta}, \hat{\lambda}_0, \ldots, \hat{\lambda}_{n-1}) = \kappa_0, \alpha_0, \eta_0, \lambda_0, \ldots, \lambda_{n-1}$, and
  \item $\sigma^{\lambda} \hat{\eta} = \sigma_0^{\lambda} \hat{\eta}$.
\end{itemize}
Remembering that $k_0|\eta_0 = \text{id}$, composing with $k_0$ results in:

- $\sigma' : \tilde{N} \prec N$,
- $\sigma'(\bar{\kappa}, \bar{\alpha}, \bar{\eta}, \lambda_0, \ldots, \lambda_{n-1}) = \kappa, a, \eta, \lambda_0, \ldots, \lambda_{n-1}$, and
- $\{\sigma')^{\bar{\eta}} = \sigma^\eta\bar{\eta}$.

In particular, clauses (a) and (c) of the lemma are satisfied. For the remaining clauses, it will be useful to analyze $\hat{\sigma}$ in more detail. The fact that $\hat{\sigma}' : \tilde{N} \prec \tilde{N}_0$ is $\tilde{\kappa}$-cofinal gives some more information about this embedding. It is this argument in which I will make use of the fact that $\kappa_0$ has countable cofinality.

(7) $\hat{\sigma} : \tilde{N} \prec \tilde{N}_0$ is $\tilde{\kappa}$-cofinal.

To see this, let $a \in \tilde{N}_0$. Since $\sigma_0 : \tilde{N} \prec \tilde{N}_0$ is $\tilde{\kappa}^+$-cofinal, there is a $b \in \tilde{N}$ of $\tilde{N}$-cardinality $\tilde{\kappa}$ with $a \in \sigma_0(b)$. Let $f : \tilde{\kappa} \rightarrow b$ be surjective, $f \in \tilde{N}$, and let $\xi < \kappa_0$ be such that $a = \sigma_0(f)(\xi)$. Since $M$ sees that $\kappa_0$ has countable cofinality, $M$ sees that $\tilde{\kappa}_0$ has countable cofinality, and it follows that $\pi^{\tilde{\kappa}_0}$ is unbounded in $\kappa_0$. So let $\beta < \tilde{\kappa}_0$ be such that $\xi < \pi(\beta)$. Let $b' = \tilde{\sigma}_0(f)^{\tilde{\pi}}\beta$, so that $a \in \pi(b')$, since $\pi(b') = \sigma_0(f)^{\pi(\beta)} \ni \sigma_0(f)(\xi) = a$. Since $\tilde{\sigma}' : \tilde{N} \prec \tilde{N}_0$ is $\tilde{\kappa}$-cofinal, there is a $c \in \tilde{N}$ of $\tilde{N}$-cardinality less than $\tilde{\kappa}$ and such that $b' \in \tilde{\sigma}'(c)$. Since the $\tilde{N}_0$-cardinality of $b'$ is less than $\tilde{\kappa}_0$, we may assume that every element of $c$ has size less than $\tilde{\kappa}$ in $\tilde{N}$, by shrinking $c$ if necessary. Now, since $\tilde{\kappa}$ is regular in $\tilde{N}$, it follows that $\bigcup c$ has $\tilde{N}$-cardinality less than $\tilde{\kappa}$, and $a \in \pi(\bigcup b') \subseteq \pi(\tilde{\sigma}'(\bigcup c)) = \tilde{\sigma}(\bigcup c)$.

(8) If $\sup_{N}(\tilde{\lambda}) \geq \tilde{\kappa}$, then $\tilde{\sigma}(\tilde{\lambda}) = \sup \tilde{\sigma}^{\tilde{\pi}}\tilde{\lambda}$, and if $\sup_{N}(\tilde{\lambda}) > \tilde{\kappa}$, then $\sigma_0(\tilde{\lambda}) = \sup \sigma_0^{\tilde{\pi}}\tilde{\lambda}$.

This follows from the previous claim, (1) and (B).

It is now obvious that clause (d) holds, that is, that $\sup \sigma'^{\tilde{\pi}}\tilde{\kappa} = \kappa_0$. This is because $\sup \sigma'^{\tilde{\pi}}\tilde{\kappa} = \sup k_0^{\tilde{\sigma}^{\tilde{\pi}}\tilde{\kappa}} = \sup \sigma(\tilde{\kappa}) = \sup k_0^{\tilde{\sigma}^{\tilde{\pi}}\kappa_0} = \kappa_0$.

The next claim shows that $\sigma'$ satisfies clause (b) of the lemma.

(9) For $i < n$, $\sup \sigma_0^{\tilde{\pi}}\tilde{\lambda}_i = \sup \tilde{\sigma}^{\tilde{\pi}}\tilde{\lambda}_i$ and $\sup \sigma'^{\tilde{\pi}}\tilde{\lambda}_i = \sup \sigma^{\tilde{\pi}}\tilde{\lambda}_i$.

The first part follows from the previous claim, because

$$\sup \sigma_0^{\tilde{\pi}}\tilde{\lambda}_i = \sup (\tilde{\sigma}(\tilde{\lambda}_i)) = \sup \tilde{\sigma}^{\tilde{\pi}}\tilde{\lambda}_i.$$

The second part follows from the first, since $\sigma' = k_0 \circ \tilde{\sigma}$ and $\sigma = k_0 \circ \sigma_0$.

Finally, let me check that clause (e) is satisfied, that is, that $\sup \sigma'^{\tilde{\pi}}(\tilde{\sigma}(\tilde{\lambda})) = \sup \sigma^{\tilde{\pi}}(\tilde{\lambda})$. This is easy to see: Both $\sigma_0$ and $\tilde{\sigma}$ cofinal, and hence,

$$\sup \sigma'^{\tilde{\pi}}(\tilde{\lambda}) = \sup k_0^{\tilde{\sigma}^{\tilde{\pi}}}(\tilde{\lambda}) = \sup \sigma^{\tilde{\pi}}(\tilde{\lambda}).$$

I will not use the following remark, but I would like to state and prove it anyway, since in some of Jensen’s writings, he defines subcompleteness by requiring that, in the notation of Definition 2.21, the embedding $\sigma'$ satisfy the “hull condition” that $\text{Hull}^N(\text{ran}(\sigma) \cup \delta) = \text{Hull}^N(\text{ran}(\sigma') \cup \delta)$, where $\delta = \delta(\mathcal{F})$ is the density of the forcing in question, instead of the “suprema condition,” that is, condition (3) of that Definition.

**Remark 3.6.** In the notation of the previous lemma, the embedding $\sigma'$ can be guaranteed to have the property that

$$\text{Hull}^N(\text{ran}(\sigma) \cup \kappa_0) = \text{Hull}^N(\text{ran}(\sigma') \cup \kappa_0).$$
Proof. The embedding constructed in the proof has this property. To see this, let me freely use notation from the proof. By construction, \( N_0 = \text{Hull}^N(\text{ran}(\sigma_0) \cup \kappa_0) \), and so, it suffices to show that \( \text{Hull}^N(\text{ran}(\hat{\sigma}) \cup \kappa_0) = N_0 \) as well, since \( \sigma/\sigma' \) result from composing \( \sigma_0/\hat{\sigma} \) with \( k_0 \). But I showed that \( \hat{\sigma} : \bar{N} \prec N_0 \) is \( \kappa \)-cofinal, which immediately implies this.

It is maybe worth mentioning that, still in the notation of Lemma 5.5, if \( \sigma' \) has the property stated in the previous remark, and actually it is enough that \( \text{Hull}^N(\text{ran}(\sigma) \cup \kappa) \), which is a weaker condition, then for any \( \bar{\lambda} > \bar{\kappa} \) of \( \bar{N} \)-cofinality greater than \( \bar{\kappa} \), if \( \sigma(\bar{\lambda}) = \sigma'(\bar{\lambda}) \), then \( \sup \sigma^{-\bar{\kappa}} = \sup \sigma'^{-\bar{\kappa}} \). So this condition is a strong form of clause (b) of the lemma. For a proof, see [10] Fact 1.6.

3.2. Friedman’s problem, the failure of square, and SCH. In Section 2 I relativized the strong reflection principle to a forcing class \( \Gamma \) by saying that every \( \Gamma \)-projective stationary set contains a continuous elementary chain of length \( \omega_1 \). I would now like to derive some consequences of this \( \Gamma \)-fragment of SRP, and the reason why these consequences arise is that certain sets are \( \Gamma \)-projective stationary. In order to be able to keep track of the sets that are responsible for these consequences, it will be useful to name them.

**Definition 3.7.** For an uncountable regular cardinal \( \kappa \), let

\[ S_{\text{lifting}}(\kappa) = \{ \text{lifting}(A, [H_\kappa]^\omega) \cap C \mid A \subseteq S_\omega^\kappa \text{ is stationary in } \kappa \text{ and } C \subseteq [H_\kappa]^\omega \text{ is club} \}. \]

Given a collection \( S \) of stationary subsets of \( H_\kappa \), the \( S \)-fragment of the strong reflection principle, \( \text{SRP}(S) \), asserts that if \( S \in S \), then there is a continuous \( \in \)-chain of length \( \omega_1 \) through \( S \).

So \( S_{\text{lifting}}(\kappa) \) consists of all the liftings of stationary subsets of \( S_\omega^\kappa \) to \( [H_\kappa]^\omega \), and their intersections with clubs; see Definition 2.4. The reason why I isolated the class \( S_{\text{lifting}} \) is that \( \text{SRP}(S_{\text{lifting}}(\kappa)) \) has some interesting consequences hinted at in the title of the present subsection, and follows from \( \Gamma \)-SRP, for the classes \( \Gamma \) of interest. The following fact has been known for a long time.

**Fact 3.8** (Feng & Jech [11, Example 2.2]). Let \( \kappa > \omega_1 \) be a regular cardinal, and let \( A \subseteq S_\omega^\kappa \) be stationary. Then the set

\[ S = \{ X \in [H_\kappa]^\omega \mid \sup(X \cap \kappa) \in A \} = \text{lifting}(A, [H_\kappa]^\omega) \]

is projective stationary.

By Observation 2.6, this can be restated by saying that for regular \( \kappa > \omega_1 \), every set in \( S_{\text{lifting}}(\kappa) \) is projective stationary. With Lemma 3.5 at my disposal, I am now ready to prove the corresponding fact about spread out sets. But I do need that \( \kappa > 2^\omega \).

**Lemma 3.9.** Let \( \kappa > 2^\omega \) be regular. Then \( S_{\text{lifting}}(\kappa) \) consists of spread out sets.

**Proof.** By Observation 2.29 it suffices to show that if \( B \subseteq S_\omega^\kappa \) is stationary, then \( S = \{ X \in [H_\kappa]^\omega \mid \sup(X \cap \kappa) \in B \} \) is spread out. To this end, let \( X \prec N = L_\theta^\kappa \), \( \sigma : \bar{N} \rightarrow X \) the inverse of the collapse of \( X \), \( S \in X \), \( \bar{N} \) countable and full, \( H_\theta \subseteq N \), where \( \theta \) is sufficiently large. Let \( a = \sigma(\bar{a}) \) be fixed, and assume that \( \kappa = \sigma(\bar{k}) \in \text{ran}(\sigma) \). By Lemma 3.5, there is an \( \omega \)-club of ordinals \( \kappa_0 \) less than \( \kappa \) such that there is a \( \sigma' : \bar{N} \prec N \) with \( \sigma'(\bar{a}) = a \), \( \sigma'(\bar{k}) = \kappa \) and \( \sup \sigma'^{-\bar{k}} = \kappa_0 \). Since \( B \subseteq S_\omega^\kappa \) is
Similarly, the exact trace \( \vec{S} \) the trace of \( \langle S, \pi \rangle \) is a simultaneous reflection point.

Let \( \text{SRP}(\kappa) \) be an ordinal and \( \kappa > \omega \) stationary. Then an ordinal \( \kappa > \omega \) is spread out. \( \Box \)

Clauses (b) and (e) of Lemma 3.5 can be used to show that in the situation of the previous lemma, \( \mathcal{S}_{\text{lifting}}(\kappa) \) actually consists of fully spread out sets.

The following theorem explains the import of \( \mathcal{S}_{\text{lifting}}(\kappa) \). Of course, only the last part mentioning \( \infty-\text{SC-SRP} \) is new. For the definition of \( \text{FP}_\kappa \), see Definition 2.1.

**Theorem 3.10.** Let \( \kappa > \omega_1 \) be regular.

1. \( \text{SRP}(\mathcal{S}_{\text{lifting}}(\kappa)) \) implies \( \text{FP}_\kappa \).
2. \( \text{SRP}(\kappa) \) implies \( \text{SRP}(\mathcal{S}_{\text{lifting}}(\kappa)) \) and hence \( \text{FP}_\kappa \).
3. If \( \kappa > 2^\omega \), then \( \infty-\text{SC-SRP}(\kappa) \) implies \( \text{SRP}(\mathcal{S}_{\text{lifting}}(\kappa)) \) and hence \( \text{FP}_\kappa \).

**Proof.* For (1) let \( A \subseteq S_\kappa^\omega \) be stationary. Then the set
\[
S = \{ X \in [\mathcal{H}_\kappa]^\omega : \sup(X \cap \kappa) \in A \}
\]
is in \( \mathcal{S}_{\text{lifting}}(\kappa) \). By \( \text{SRP}(\mathcal{S}_{\text{lifting}}(\kappa)) \), let \( \langle M_i \mid i < \omega_1 \rangle \) be a continuous elementary chain through \( S \). Define \( f : \omega_1 \to A \) by \( f(i) = \sup M_i \cap \kappa \). Then \( f \) is a normal function, verifying the instance of \( \text{FP}_\kappa \) given by \( A \).

Now (2) follows from Fact 3.3 and (1) and (3) from Lemma 3.9 and (1). \( \Box \)

In item (3) of the previous theorem, \( \infty-\text{SC-SRP}(\kappa) \) can be replaced with \( \text{SC-SRP}(\kappa) \), since the relevant sets are fully spread out, as pointed out before.

It is well-known that for a cardinal \( \kappa \), \( \text{FP}_{\kappa^+} \) implies the failure of Jensen’s principle \( \square_{\kappa^+} \), as a consequence of the previous theorem, one obtains:

**Corollary 3.11.** \( \infty-\text{SC-SRP} \) implies that for every cardinal \( \kappa \geq 2^\omega \), \( \square_\kappa \) fails.

Again, \( \infty-\text{SC-SRP} \) is sufficient here. The following terminology expands on [17].

**Definition 3.12.** Let \( \kappa \) be an uncountable regular cardinal.

The strong Friedman Property at \( \kappa \), denoted \( \text{SFP}_\kappa \), says that for any partition \( \langle D_i \mid i < \omega_1 \rangle \) of \( \omega_1 \) into stationary sets, and for any sequence \( \langle S_i \mid i < \omega_1 \rangle \) of stationary subsets of \( S_\kappa^\omega \), there is a normal function \( f : \omega_1 \to \bigcup_{i < \omega_1} S_i \) such that for every \( i < \omega_1 \), \( f^{-1}D_i \subseteq S_i \).

This is a somewhat technical concept, but I will extract from it something more natural. The following expands on [20] Def. 8.17.

**Definition 3.13.** Let \( \kappa \) be a cardinal of uncountable cofinality, and let \( S \subseteq \kappa \) be stationary. Then an ordinal \( \delta < \kappa \) is a reflection point of \( S \) if \( \delta \) has uncountable cofinality and \( S \cap \delta \) is stationary in \( \delta \). It is an exact reflection point of \( S \) if \( S \cap \delta \) contains a club in \( \delta \).

If \( \vec{S} = \langle S_i \mid i < \lambda \rangle \) is a sequence of stationary subsets of \( \kappa \), then an ordinal \( \delta < \kappa \) is a simultaneous reflection point of \( \vec{S} \) if for every \( i < \lambda \), \( \delta \) is a reflection point of \( S_i \). It is an exact simultaneous reflection point of \( \vec{S} \) if it is a simultaneous reflection point of \( \vec{S} \) and \( \delta \cap (\bigcup_{i < \lambda} S_i) \) contains a club in \( \delta \).

The trace of \( S \), denoted \( \text{Tr}(S) \) is the set of reflection points of \( S \), and similarly, the trace of \( \vec{S} \), denoted \( \text{Tr}(\vec{S}) \), is the set of simultaneous reflection points of \( \vec{S} \). Similarly, the exact trace of \( S \), denoted \( \text{eTr}(S) \), is the set of exact reflection points of \( S \), and \( \text{eTr}(\vec{S}) \) is the set of exact reflection points of \( \vec{S} \).
Clearly, $\text{FP}_\kappa$ implies not only that every stationary subset $A$ of $S_\omega^n$ has a reflection point, but that it has an exact reflection point. $\text{SFP}_\kappa$ has a similar effect on $\omega_1$-sequences of stationary subsets of $S_\omega^n$; as the following observation shows - note that it obviously implies (a) if $S = S_\omega^n$, and hence each of the equivalent conditions stated. In fact, the observation shows that (a) is maybe a more natural version of $\text{SFP}_\kappa$.

**Observation 3.14.** Let $\kappa > \omega_1$ be regular and fix a stationary subset $S$ of $\kappa$. The following are equivalent:

(a) Whenever $\hat{S} = \langle S_i \mid i < \omega_1 \rangle$ is a sequence stationary subsets of $S$, there are a partition $\langle D_i \mid i < \omega_1 \rangle$ of $\omega_1$ into stationary sets and a normal function $f : \omega_1 \to \kappa$ such that for all $i < \omega_1$, $f^a D_i \subseteq S_i$.

(b) Whenever $\hat{S} = \langle S_i \mid i < \omega_1 \rangle$ is a sequence of stationary subsets of $S$, then $\text{eTr}(\hat{S}) \neq \emptyset$.

(c) Whenever $\hat{S} = \langle S_i \mid i < \omega_1 \rangle$ is a sequence of stationary subsets of $S$, then $\text{eTr}(\hat{S})$ is stationary.

**Proof.** (a) $\Rightarrow$ (c) Let $\hat{S}$ be as in (c) and let $C \subseteq \kappa$ be club. Then let $\bar{D}$, $f$ be as in (a) with respect to the sequence $\langle S_i \cap C \mid i < \omega_1 \rangle$. Letting $\delta = \sup \text{ran}(f)$, it follows that $\delta \in C \cap \text{eTr}(\hat{S})$.

(c) $\Rightarrow$ (b) Let $\hat{S} = \langle S_i \mid i < \omega_1 \rangle$ be a sequence of stationary subsets of $S_\omega^n$. Let $\hat{S}' = \langle S_i' \mid i < \omega_1 \rangle$ be a refinement of $\hat{S}$ into a sequence of pairwise disjoint stationary sets. Such a sequence $\hat{S}'$ exists because $\kappa > \omega_1$, so that the nonstationary ideal on $\kappa$ is “nowhere $\omega_2$-saturated”, see Baumgartner-Hajnal-Máté [5, Lemma 2.1] for details. By (c) let $\delta$ be an exact reflection point of $\hat{S}'$. Let $C \subseteq (\delta \cap \bigcup_{i < \omega_1} S_i)$ be club, and let $f : \omega_1 \to C$ be the monotone enumeration of $C$. For $i < \omega_1$, let $D_i = f^{-1} S_i'$. Then $\langle D_i \mid i < \omega_1 \rangle$ is a partition of $\omega_1$ into stationary sets such that for every $i < \omega_1$, $f^a D_i \subseteq S'_i \subseteq S_i$.

The following fact is usually stated assuming some variation of $\text{SFP}_\kappa$ in place of my assumption, but it can be filtered through the “exact” reflection property of the previous observation. See Foreman-Magidor-Shelah [13], or Jech [26, p. 686, proof of Theorem 37.13]. Note that if $\delta$ is an exact reflection point of a sequence $\hat{S}$, then $\delta$ is a reflection point of each $S_i$, but if $T$ is a stationary subset of $\kappa$’s disjoint from $\bigcup \hat{S}$, then $\delta$ is not a reflection point of $T$, and this is why I refer to it as an exact reflection point. This property is used in the proof of the following fact.

**Fact 3.15.** Let $\kappa > \omega_1$ be a regular cardinal, and let $S$ be a stationary subset of $\kappa$ such that any $\omega_1$-sequence of stationary subsets of $S$ has an exact simultaneous reflection point. Then $\kappa^{\omega_1} = \kappa$.

**Proof.** Fix a sequence $\langle S_i \mid i < \kappa \rangle$ of pairwise disjoint stationary subsets of $S$. If $x \in [\kappa]^{\omega_1}$ and $\delta$ is an exact simultaneous reflection point for $\hat{S}|x$, then $x = R_\delta = \{i < \kappa \mid \delta$ is a reflection point of $S_i\}$. Thus, $[\kappa]^{\omega_1} \subseteq \{ R_\delta \mid \delta < \kappa \}$.

The following is due to Feng & Jech [11, Example 2.3].

**Lemma 3.16.** Let $\kappa > \omega_1$ be regular. Let $\bar{D} = \langle D_i \mid i < \omega_1 \rangle$ be a partition of $\omega_1$ into stationary sets which is maximal in the sense that for every stationary $T \subseteq \omega_1$,
there is an \(i < \omega_1\) such that \(D_i \cap T\) is stationary. Let \(\vec{S} = \langle S_i \mid i < \omega_1\rangle\) be a sequence of stationary subsets of \(S^\kappa_0\). Then the set

\[
S = \{X \in [H]^{\omega_1} \mid \forall i < \omega_1 \ (X \cap \omega_1 \in D_i \rightarrow \sup(X \cap \kappa) \in S_i)\}
\]

is projective stationary.

The status of the maximality assumption on \(\vec{D}\) here is interesting. First, let me note:

**Remark 3.17.** Maximal partitions \(\vec{D}\) of \(\omega_1\) into stationary sets as in the previous lemma are easy to construct: start with an arbitrary partition \(\vec{D}'\) of \(\omega_1\) into stationary sets. It can be identified with the function \(f' : \omega_1 \rightarrow \omega_1\) defined by \(i \in D'\_{f'(i)}\). Modify \(f'\) to the regressive function \(f : \omega_1 \rightarrow \omega_1\) defined by \(f(i) = f'(i)\) if \(f'(i) < i\), and \(f(i) = 0\) otherwise. The corresponding partition \(\langle D_i \mid i < \omega_1\rangle\) with \(D_i = \{\alpha \mid f(\alpha) = i\}\) is then as wished: each \(D_i\) is stationary, because it contains \(D'\_{f(i)}\) and \(T \subseteq \omega_1\) is stationary, then \(f[T]\) is constant on a stationary subset of \(T\), say with value \(i_0\), so \(T \cap D_{i_0}\) is stationary.

Following is the version of Feng & Jech’s Lemma 3.16, with “spread out” in place of “projective stationary.” I have to strengthen the assumption that \(\kappa > \omega_1\) to \(\kappa > 2^\omega\), but I can drop the maximality assumption on the partition \(\vec{D}\).

**Lemma 3.18.** Let \(\kappa > 2^\omega\) be regular. Let \(\vec{D} = \langle D_i \mid i < \omega_1\rangle\) be a partition of \(\omega_1\) into stationary sets and \(\vec{S} = \langle S_i \mid i < \omega_1\rangle\) a sequence of stationary subsets of \(S^\kappa_0\). Let

\[
S = \{X \in [H]^{\omega_1} \mid \forall i < \omega_1 \ (X \cap \omega_1 \in D_i \rightarrow \sup(X \cap \kappa) \in S_i)\}.
\]

Then \(S\) is spread out.

**Proof.** Let \(\theta\) be sufficiently large, \(H_\theta \subseteq L^\kappa_\theta = N \models \text{ZFC}^-\), \(X \prec N\) countable and full with \(S \in X\), and fix \(a \in X\). Let \(i < \omega_1\) be such that \(\delta = X \cap \omega_1 \in D_i\). We can now use Lemma 3.16 as in the proof of Lemma 3.19 showing that there are a \(Y \prec N\) and an isomorphism \(\pi' : X \rightarrow Y\) fixing \(a\) such that \(\kappa_0 = \sup(Y \cap \kappa) \in S_i\). Since this isomorphism has to fix the countable ordinals, it follows that \(Y \cap \omega_1 = X \cap \omega_1 \in S_i\), and hence that \(Y \cap H_\kappa \in S\).

Again, using properties (b) and (e) of Lemma 3.5, one obtains that in the previous lemma, \(S\) is fully spread out.

Since spread out sets are also projective stationary (see Observation 2.28), the previous lemma shows that if \(\kappa > 2^\omega\), then it is not necessary to assume \(\vec{D}\) is maximal in Lemma 3.16. This seems to be new, and I am not sure how one would prove this without using something along the lines of Lemma 3.5.

**Theorem 3.19.** Let \(\kappa > 2^\omega\) be regular. Then \(\infty\text{-SC-SRP}(\kappa)\) implies \(\text{SFP}_\kappa\).

**Proof.** Let \(\vec{D}, \vec{S}\) be as in Definition 3.12. By Lemma 3.18, the set

\[
S = \{X \in [H]^{\omega_1} \mid \forall i < \omega_1 \ (X \cap \omega_1 \in D_i \rightarrow \sup(X \cap \kappa) \in S_i)\}
\]

is \(\infty\text{-SC}\)-projective stationary. By \(\infty\text{-SC-SRP}\), let \(\langle M_i \mid i < \omega_1\rangle\) be a continuous \(\in\)-chain through \(S\). Let \(C = \{\alpha < \omega_1 \mid M_\alpha \cap \omega_1 = \alpha\}\). Clearly, \(C\) is closed and unbounded in \(\omega_1\). Define \(f : C \rightarrow \kappa\) by \(f(i) = \sup(M_i \cap \kappa)\). Then \(f\) is strictly increasing and continuous in the sense that if \(\alpha\) is a countable limit point of \(C\), then \(f(\alpha) = \sup_{\beta \in C \cap \alpha} f(\beta)\). Moreover, for \(j \in C\), if \(j \in D_i\), then \(f(j) \in S_i\), since
j = M_j \cap \omega_1 \in D_i and hence sup(M_j \cap \kappa) \in S_i, as M_j \in S. So f is almost like the function postulated to exist by SFP_\kappa, except that it is only defined on C, a club subset of \omega_1, rather than on all of \omega_1. This form of SFP_\kappa is enough for the applications, so let me just sketch how to obtain the full version from this.

All that needs to be done is fill in the gaps. Let \langle \zeta_i \mid i < \omega_1 \rangle be the monotone enumeration of C. Fixing i < \omega_1, consider the forcing notion \mathbb{P} consisting of all functions h : (\zeta_i, \alpha] \rightarrow \kappa, continuous on their domains, such that (1), \zeta_i < \alpha < \omega_1, (2), for all \xi \in \text{dom}(h), if j is such that \xi \in D_j, then h(\xi) \in S_j, and (3), if \zeta_i + 1 \in \text{dom}(h), then h(\zeta_i + 1) > f(\zeta_i). This forcing is stationary set preserving, and for every \alpha \in (\zeta_i, \omega_1), the set D_\alpha of conditions in \mathbb{P} whose domain contains \alpha is dense in \mathbb{P}. The latter property is what I need here, and an argument establishing it can be found in [20] p. 686. Now let G_i be M_{\zeta_{i+1}}-generic for \mathbb{P} (we may assume that each element of the chain is an elementary submodel of \langle H_\kappa, \in, \vec{D}, \vec{S} \rangle, so that \mathbb{P} belongs to every model in the chain), and let g_i = \bigcup G_i. It then follows that dom(g_i) = [\zeta_i + 1, \zeta_{i+1}], g_i(\zeta_i + 1) > f(\zeta_i), sup g_i, \zeta_{i+1} = sup(M_{i+1} \cap \kappa) = f(\zeta_{i+1}), and for all \alpha \in (\zeta_i, \zeta_{i+1}), if \alpha \in D_j, then g_i(\alpha) \in S_j. Hence, if we define f' = f \cup \bigcup_{i < \omega_1} g_i, then f' is as desired.

Again, SC-SRP(\kappa) is sufficient in this theorem. It has been well-known for a long time that if \kappa > \omega_1 is regular, then SRP(\kappa) implies the version of SFP_\kappa in which it is assumed that the partition \vec{D} used (see Definition 3.12) is maximal in the sense of Lemma 3.16. The previous theorem shows that already the subcomplete fragment of SRP(\kappa) implies the full SFP_\kappa principle, provided that \kappa > 2^{\omega_1}. In this corollary, SC-SRP is enough.

Corollary 3.20. \infty-SC-SRP implies that for regular \kappa > 2^{\omega_1}, \kappa^{\omega_1} = \kappa.

Proof. This is by the previous theorem, Observation 3.14 and Fact 3.15.

Results of [10] can be used to derive further consequences of Theorem 3.19 in terms of the failure of weak square principles. I will not go into the details here, but I would like to keep track of the fragment of SRP responsible for the latest consequences mentioned. First, one could ask:

Question 3.21. Assume \kappa > \omega_1 is regular. Does SRP(S_{\text{lifting}}(\kappa)) imply SFP_\kappa?

On the positive side, one can list the sets used to derive SFP_\kappa.

Definition 3.22. Given an uncountable regular cardinal \kappa, a partition \vec{D} of \omega_1 into stationary sets and an \omega_1-sequence \vec{S} of stationary subsets of S^\omega_\omega, call the pair \langle \vec{D}, \vec{S} \rangle a \kappa-correspondence, and define the lifting of such a correspondence to any X with \kappa \subseteq X by

\text{lifting}(⟨ \vec{D}, \vec{S}, [X]^\omega ⟩) = \{ x \in [X]^\omega \mid \forall i < \omega_1 \ (x \cap \omega_1 \in D_i \rightarrow sup(x \cap \kappa) \in S_i) \}.

and then define the class of liftings of correspondences by letting

\mathcal{S}_\text{corr}(\kappa) = \{ \text{lifting}(⟨ \vec{D}, \vec{S}, [H_\kappa]^\omega ⟩) \cap C \mid \kappa > \omega_1, \langle \vec{D}, \vec{S} \rangle is a \kappa-correspondence and C \subseteq [H_\kappa]^\omega is club}. 

Clearly then, for \kappa > 2^{\omega_1}, \mathcal{S}_\text{corr}(\kappa) consists of spread out sets, by Lemma 3.18 and SRP(\mathcal{S}_\text{corr}(\kappa)) implies SFP_\kappa, by the proof of Theorem 3.19. In fact, fixing one partition \vec{D} as in Definition 3.22 would suffice.
Corollary 3.23. \(*\)-SC-SRP implies SCH. Actually, SRP($S_{\text{corr}}(\kappa)$), for all $\kappa > 2^\omega$, suffices.

Proof. We have to show that if $\lambda$ is a singular cardinal with $2^{cf(\lambda)} < \lambda$, then $\lambda^{cf(\lambda)} = \lambda^+$. By Silver’s Theorem (see [26, Theorem 8.13]), it suffices to prove this in the case that $\lambda$ has countable cofinality. In this case, we have that $\lambda > 2^\omega$. Since SRP($S_{\infty}\text{-SC}$) holds, it follows from Corollary 3.20 that $(\lambda^+)^{\omega_1} = \lambda^+$. Thus we have

$$\lambda^{+} \leq \lambda^{cf(\lambda)} = \lambda^+ \leq (\lambda^+)^{\omega_1} = \lambda^+$$

as wished. □

Of course, SC-SRP is sufficient in this corollary.

3.3. Mutual stationarity. The ideas of the previous subsection can be carried a little further. Let me recall the notion of mutual stationarity, introduced by Foreman & Magidor [13].

Definition 3.24. Let $K$ be a collection of regular cardinals with supremum $\delta$, and let $\vec{S} = \langle S_\kappa | \kappa \in K \rangle$ be a sequence such that for every $\kappa \in K$, $S_\kappa$ is a subset of $\kappa$. Then $\vec{S}$ is mutually stationary if for every algebra $A$ on $\delta$, there is an $N \prec A$ such that for all $\kappa \in N \cap K$, sup($N \cap \kappa$) $\in S_\kappa$.

It is easy to see that if $\vec{S}$ is mutually stationary, then for all $\kappa \in K$, $S_\kappa$ is a stationary subset of $\kappa$. The following beautiful and fundamental fact on mutual stationarity was proved in the article in which the concept was introduced and gives a condition under which the converse is also true.

Fact 3.25 (Foreman & Magidor [13, Thm. 7]). Let $K$ be a set of uncountable regular cardinals, and let $\vec{S} = \langle S_\kappa | \kappa \in K \rangle$ be a sequence such that for every $\kappa \in K$, $S_\kappa$ is a stationary subset of $S^\kappa$. Then, $\vec{S}$ is mutually stationary: for any algebra $A$ on sup$K$, there is a countable $N \prec A$ such that for all $\kappa \in N \cap K$, sup($N \cap \kappa$) $\in S_\kappa$.

It seems as though the following connection has not been made before:

Corollary 3.26. Let $K$ be a set of regular cardinals with min$(K) > \omega_1$, and let $\vec{S} = \langle S_\kappa | \kappa \in K \rangle$ be a sequence such that for every $\kappa \in K$, $S_\kappa \subseteq S^\kappa$ is stationary in $\kappa$. Let $\delta = \text{sup} K$. Then the set $S = \{ M \in [H_\delta]^{\omega_1} | \forall \kappa \in M \cap K \text{ sup}(M \cap \kappa) \in S_\kappa \}$ is projective stationary.

Proof. This is because if $A \subseteq \omega_1$ is stationary, and if we let $K' = K \cup \{ \omega_1 \}$ and $\vec{S}' = \vec{S} \cup \{ \omega_1, A \}$, then we can apply Fact 3.25 to these objects, showing that the set $S_A = \{ M \in S | M \cap \omega_1 \in A \}$ is a stationary subset of $[H_\delta]^{\omega_1}$. □
Corollary 3.27. Let $K$ be a set of regular cardinals with $\min(K) > \omega_1$, and let
$\bar{S} = \langle S_{\kappa,i} \mid \kappa \in K, i < \omega_1 \rangle$ be a sequence such that for every $\kappa \in K$ and every
$i < \omega_1$, $S_{\kappa,i} \subseteq S^*_\kappa$ is stationary in $\kappa$. Let $\delta = \sup K$. Let $\langle D_i \mid i < \omega_1 \rangle$ be a
maximal partition of $\omega_1$ into stationary sets (in the sense of Lemma 3.16). Then
the set
$$S = \{ M \in [H_{s}]^{\omega} \mid \forall \kappa \in M \cap K \forall i < \omega_1 \ (M \cap \omega_1 \in D_i \implies \sup(M \cap \kappa) \in S_{\kappa,i}) \}$$
is projective stationary.

Proof. Let $B \subseteq \omega_1$ be stationary, and let $i < \omega_1$ be such that $D_i \cap B$ is stationary.
Let $K' = K \cup \{ \omega_1 \}$, and consider the sequence $\langle S'_{\kappa} \mid \kappa \in K' \rangle$ defined by letting
$S'_{\kappa} = S_{\kappa,i}$ for $\kappa \in K$ and $S'_{\omega_1} = D_i \cap B$. By Fact 3.25 the set
$\bar{S} = \{ M \in [H_{s}]^{\omega} \mid \forall \kappa \in M \cap K' \sup(M \cap \kappa) \in S'_{\kappa} \}$ is stationary. But $\omega_1 \in M$, for a club $C$ of
$M$, and $\bar{S} \cap C \subseteq S_B = \{ M \in S \mid M \cap \omega_1 \in B \}$, showing that $S_B$ is stationary. □

This connection to mutual stationarity gives rise to a somewhat “diagonal” reflection principle for sequences of stationary sets of ordinals which follows from SRP, in contrast to others that I will discuss in Section 4. It is a kind of simultaneous reflection principle for sequences of stationary sets that live on different regular cardinals. To motivate it, recall that Observation 3.14 shows that a weak version of SRP
for sequences of stationary sets of ordinals which follows from SRP, let $\bar{T} = \langle eTr(S_{\kappa}) \mid \kappa \in K \rangle$
is mutually stationary.

Theorem 3.28. Assume SRP. Let $K$ be a set of regular cardinals with $\min(K) > \omega_1$. Let $\bar{S} = \langle S_{\kappa,i} \mid \kappa \in K, i < \omega_1 \rangle$ be such that for every $\kappa \in K$ and $i < \omega_1$, $S_{\kappa,i}$
is a subset of $S^*_\kappa$ stationary in $\kappa$. For $\kappa \in K$, let $\bar{T}_\kappa = \langle S_{\kappa,i} \mid i < \omega_1 \rangle$. Then the sequence
$$\bar{T} = \langle eTr(S_{\kappa}) \mid \kappa \in K \rangle$$
is mutually stationary.

Proof. Let $\delta = (\sup(K))^+$. Fix a partition $\langle A_i \mid i < \omega_1 \rangle$ of $\omega_1$ into stationary sets
which is a maximal antichain. Let $S$ be the set of countable $M < H_{s}$ such that if $M \cap \omega_1 \in A_i$, then for all $\kappa \in M \cap K$, $\sup(M \cap \kappa) \in S_{\kappa,i}$. By Corollary 3.27 this set is projective stationary. By SRP, let $\langle M_{\alpha} \mid \alpha < \omega_1 \rangle$ be a continuous elementary
sequence $S$. Let $M = \bigcup_{\alpha < \omega_1} M_{\alpha}$. Then $M \prec H_{s}$. We claim that $M$ verifies that $\bar{T}$ is mutually stationary. To see this, suppose $\kappa \in M \cap K$. We have to show that for every $i < \omega_1$, $s_{\kappa} = \sup(M \cap \kappa) \in eTr(S_{\kappa,i})$. That is, we have to show that for every $i < \omega_1$, $s_{\kappa}$ is a reflection point of $S_{\kappa,i}$, and that $\bigcup_{i < \omega_1} S_{\kappa,i} \cap s_{\kappa}$ contains a club.

For the first part, fix any countable ordinal $i$. To see that $S_{\kappa,i} \cap s_{\kappa}$ is stationary, let $D \subseteq s_{\kappa}$ be club. We have to show that $S_{\kappa,i} \cap D \neq \emptyset$. Let $\beta < \omega_1$ be least such that $\kappa \in M_{\beta}$, and define, for $j \in [\beta, \omega_1)$, $\xi_j = \sup(M_{j} \cap \kappa)$. Then $\xi$ is strictly increasing, continuous, and cofinal in $s_{\kappa}$. That is, $C = \{ \xi_j \mid \beta \leq j < \omega_1 \}$ is club in $s_{\kappa}$. Since $c_{f}(s_{\kappa}) = \omega_1$, $C \cap D$ is club in $s_{\kappa}$, and hence, $D = \{ j \in [\beta, \omega_1) \mid \xi_j \in D \}$ is club in $\omega_1$. Similarly, the set $E = \{ j < \omega_1 \mid j = M_j \cap \omega_1 \}$ is club in $\omega_1$. Now since
$T_i$ is stationary in $\omega_1$, we can pick $\alpha \in T_i \cap \check{D} \cap E$. Then $\xi_\alpha \in D$, since $\alpha \in \check{D}$, and $\alpha = M_\alpha \cap \omega_1 \in T_i$. Since $M_\alpha \in S$ and $\alpha \geq \beta$, that is, $\kappa \in M_\alpha$, it follows that $\xi_\alpha = \sup(M_\alpha \cap \kappa) \in S_{\kappa,i}$. Thus, $\xi_\alpha \in S_{\kappa,i} \cap D$, as wished.

For the second part, note that the club $C$ defined in the previous paragraph is contained in $\bigcup_{i<\omega_1} S_{\kappa,i}$.

I will show in the following that the same conclusion can be drawn from $\omega_1$-SRP$^\infty$ under the additional assumption that CH holds. Essentially, this amounts to showing a version of Corollary 3.26 with “spread out” in place of “projective stationary”. To this end, I will use the following strengthening of Lemma 3.5. The argument will be a construction that proceeds in many steps, each of which will be an application of Lemma 3.5.

**Lemma 3.29.** Let $K$ be a set of regular cardinals such that $\min(K) > 2^\omega$ and such that whenever $\kappa < \lambda$, $\kappa, \lambda \in K$, then $\kappa^+ < \lambda$. Let $\check{S} = \langle S_\kappa \mid \kappa \in K \rangle$ be such that for every $\kappa \in K$, $S_\kappa \subseteq S_\kappa^+$ is stationary in $\kappa$. Let $\theta > 2^{2^{\omega}(\kappa)}$ be regular, $N$ a transitive model of ZFC$^-$ that has a definable well-order, with $H_\theta \subseteq N$. Let $\sigma : \check{N} \rightarrow N$, where $\check{N}$ is countable and full and $K \in \text{ran}(\sigma)$. Let $\check{K}$ be the preimage of $K$, and let $\check{a}$ be some element of $\check{N}$.

Then there is an embedding $\sigma' : \check{N} \rightarrow N$ with the following properties:

(a) $\sigma(\check{a}) = \sigma'(\check{a})$ and $\sigma'(K) = K$,

(b) for every $\check{\kappa} \in \check{K}$, $\sup \sigma'^+ \check{\kappa} \in S_{\sigma'(\check{\kappa})}$.

**Proof.** We may assume that $K$ is infinite. Let $\langle \check{a}_n \mid n < \omega \rangle$ enumerate $\check{K}$. Let us also fix an enumeration $\langle \check{\kappa}_n \mid n < \omega \rangle$ of $\check{N}$. Also, letting $\rho = \sup(K)$, let us fix, for every $\alpha \in \check{S}_\rho$, an increasing and cofinal function $f_\alpha : \omega \rightarrow \alpha$.

We will construct sequences $\langle \sigma'_n \mid n < \omega \rangle$, $\langle \check{\kappa}_n \mid n < \omega \rangle$, $\langle \check{a}_n \mid n < \omega \rangle$ and $\langle \beta^n_{m,\ell} \mid m \leq \ell \leq n < \omega \rangle$ by simultaneous recursion on $n$, satisfying the following properties, for every $n < \omega$:

(i) $\sigma'_n : \check{N} \rightarrow N$.

(ii) Let $\check{\kappa}_n = \sup \sigma'^+ \check{\kappa}_n$ and $\kappa_n = \sigma'_n(\check{\kappa}_n)$. Then $\check{\kappa}_n \in S_{\kappa_n}$.

(iii) $\sigma'_n|\check{K}, \check{a} = \sigma|\check{K}, \check{a}$.

(iv) For $m \leq \sigma_n, \sigma_n(\check{\kappa}_m) = \sigma'_n(\check{\kappa}_m)$. Then $\check{\kappa}_m \in S_{\kappa_m}$.

(v) For $m < \ell$, $\sigma'_n(\check{\kappa}_m) = \sigma'_n(\check{\kappa}_\ell)$ and $\sigma'_n(\check{\kappa}_m) = \sup \sigma'^+ \check{\kappa}_m$.

(vi) For $m \leq \ell \leq n$, let $\beta^m_{m,\ell} < \check{\kappa}_m$ be the least ordinal $\beta$ such that $\sigma'_n(\beta) > f_{\check{\kappa}_m}(\ell)$. Then $\sigma'_n(\beta^m_{m,\ell}) = \sigma'_{n+1}(\beta^m_{m,\ell})$. Moreover, for all $k < n$ and all $m \leq \ell \leq k$, $\sigma'_n(\beta^m_{m,\ell}) = \sigma'_n(\beta^m_{m,\ell})$.

To get started, let $\kappa_0 = \sigma(\check{\kappa}_0)$ and apply Lemma 3.5 to $\kappa_0$ and $S_{\kappa_0}$. We don’t need the full strength of the lemma in step 0 of the construction, but just conditions (a) and (d) (so we can let $\eta = 0$). This gives us a $\sigma'_0 : \check{N} \rightarrow N$ that moves $\check{K}$, $\check{a}$, $\check{\kappa}_0$ the same way $\sigma$ does, and such that letting $\check{\kappa}_0 = \sup \sigma'^+ \check{\kappa}_0$, we have that $\check{\kappa}_0 \in S_{\kappa_0}$, since there is an $\omega$-club in $\kappa_0$ of possibilities for $\check{\kappa}$ and $S_{\kappa_0}$ is a stationary subset of $\kappa_0$ consisting of ordinals of countable cofinality. Thus, conditions (ii)(iii) are satisfied at $n = 0$, and the remaining conditions are vacuous at $n = 0$. Define $\beta^0_{0,0}$ as in condition (vi). This is possible because $\sigma'^+ \check{\kappa}_0$ is cofinal in $\check{\kappa}_0$.

Now let us assume that $\langle \sigma'_m \mid m \leq n \rangle$ have been constructed, and $\langle \kappa_m \mid m \leq n \rangle$, $\langle \check{\kappa}_m \mid m \leq n \rangle$ and $\langle \beta^m_{k,\ell} \mid m \leq \ell \leq k \leq n \rangle$ have been defined accordingly, so that all of the conditions are satisfied at each $m \leq n$. Let $\kappa_{n+1} = \sigma'_n(\check{\kappa}_{n+1})$. Let $\eta = \max(\{0\} \cup \{(\kappa_m \mid m \leq n) \cap \kappa_{n+1}\})$. Since $\kappa_{n+1} \in K$, $\eta < \kappa_{n+1}$ and either
Now apply Lemma 3.5 to \( \sigma = 0 \) or \( \sigma \) embedding the finite set \( \{ \eta \in K \mid \eta \in \sigma \text{ conditions (i), (ii), (iii) and (iv)} \} \). To check condition (v), let \( \sup \kappa \text{ inductively}, \) the conditions are satisfied at \( \sup \kappa \) because \( \sup \kappa \text{ define and } \) remainder of this condition is again clear because \( \sup \kappa \geq n \). Let us check that the conditions are satisfied at \( \sup \kappa \). Observe that for every \( \bar{x} \in \bar{N} \), \( \langle \sigma_n \bar{x} \rangle \mid n < \omega \rangle \) is eventually constant, so we can define \( \sigma' : \bar{N} \rightarrow N \) by letting \( \sigma'(\bar{x}) \) be the eventual value of this sequence, in other words,

\[
\sigma'(\bar{a}) = \sigma'_n(\bar{a})
\]

for every \( n < \omega \). We claim that \( \sigma' \) is the desired embedding.

First, note that \( \sigma' : \bar{N} \rightarrow N \), because if \( \varphi(\bar{x}) \) is a formula in the language of \( N \) with \( j < \omega \) free variables and \( \bar{a}_{n_0}, \ldots, \bar{a}_{n_j} \) are parameters in \( \bar{N} \), then if we choose \( n \geq \max\{n_0, \ldots, n_j - 1\} \), we have that \( \sigma'_{\bar{a}} = \sigma'_n(\bar{a}) \), and so

\[
\bar{N} \models \varphi(\bar{a}) \iff N \models \varphi(\sigma'_n(\bar{a})) \iff N \models \varphi(\sigma'(\bar{a}))
\]

since \( \sigma'_n \) is an elementary embedding. Obviously, we have that \( \sigma'(\bar{k}) = \kappa_n \), for every \( n < \omega \), and \( \sigma'(\bar{a}) = \sigma(\bar{a}) \). Thus, condition (a) is satisfied. Let us check the remaining condition (b). Let \( \bar{a} \in \bar{K} \), say \( \bar{a} = \bar{k} \). We have to show that \( \sup \sigma''\bar{k} \in \bar{K} \). Since \( \bar{K} = \kappa_n \) and \( \kappa_n \in S_{\kappa_n} \), it will suffice to show that \( \sup \sigma''\bar{k} = \bar{k} \). Clearly, \( \sigma''\bar{k} \subseteq \bar{k} \), since for every \( \xi < \bar{k} \), there is a \( k < \omega \) with \( k \geq n \) such that \( \sigma'_{\bar{a}} = \sigma'_k(\bar{a}) \), but by condition (v)

\[
\sup \sigma''\bar{k} = \sup \sigma''\bar{k} = \bar{k}.
\]

Thus, \( \sigma''\bar{k} \subseteq \bar{k} \). For the other inequality, we show that \( \sigma''\bar{k} \) is unbounded in \( \bar{k} \). Since \( \text{ran}(f_{\bar{k}}) \) is unbounded in \( \bar{k} \), it suffices to show that for every \( \ell < \omega \), there is a \( \beta < \bar{k}_\ell \) such that \( \sigma'(\bar{a}) > f_{\bar{k}}(\ell) \). We may clearly assume that \( \ell > n \). Let \( k < \omega \), \( k \geq \max\{n, \ell\} \). Consider \( \beta = \beta_{k(\ell)} \). By definition, \( \beta < \bar{k}_\ell \) and \( \sigma'(\bar{a}) > f_{\bar{k}}(\ell) \). Moreover, by the same condition, we have that \( \sigma'(\bar{a}) = \sigma'_k(\beta) > f_{\bar{k}}(\ell) \), as claimed. \( \Box \)
We thus obtain the following version of Foreman & Magidor’s mutual stationarity Fact 3.25, or rather, the equivalent Corollary 3.26.

**Corollary 3.30.** Let $K$ be a set of regular cardinals such that $\min(K) > 2^\omega$ and such that whenever $\kappa < \lambda$, $\kappa, \lambda \in K$, then $\kappa^\omega < \lambda$. Let $\vec{S} = \langle S_{\kappa} \mid \kappa \in K, i < \omega_1 \rangle$ be such that for every $\kappa \in K$, $S_{\kappa} \subseteq S_{\kappa}^\omega$ is stationary in $\kappa$. Let $\rho \geq \sup(K)$. Then the set

$$S = \{ M \in [H_\rho]^\omega \mid \forall \kappa \in M \cap K \sup(M \cap \kappa) \in S_{\kappa}, \sup(M \cap \kappa) \in S_{\kappa,i} \}$$

is spread out.

Instead of providing a proof of this, let me build in a correspondence as before, and prove the following more general statement. This is the version of Corollary 3.27.

**Corollary 3.31.** Let $K$ be a set of regular cardinals such that $\min(K) > 2^\omega$ and such that whenever $\kappa < \lambda$, $\kappa, \lambda \in K$, then $\kappa^\omega < \lambda$. Let $\vec{S} = \langle S_{\kappa} \mid \kappa \in K, i < \omega_1 \rangle$ be such that for every $\kappa \in K$ and every $i < \omega_1$, $S_{\kappa,i} \subseteq S_{\kappa}^\omega$ is stationary in $\kappa$. Let $\vec{D}_i \mid i < \omega_1 \rangle$ be a partition of $\omega_1$ into stationary sets, and let $\rho \geq \sup(K)$ be regular. Then the set

$$S = \{ M \in [H_\rho]^\omega \mid \forall \kappa \in M \cap K \forall i < \omega_1 \ (M \cap \omega_1 \in D_i \implies \sup(M \cap \kappa) \in S_{\kappa,i}) \}$$

is spread out.

**Proof.** This is an immediate application of Lemma 3.29. Namely, to show that $S$ is spread out, let $X \prec L^A$ as usual, and let $\sigma : N \rightarrow X$ be the inverse of the Mostowski collapse of $X$, where we assume that $\bar{N}$ is full. As usual, we may assume that $X$ contains the parameters we care about; in this case we choose $K$. Let $\bar{K} = \sigma^{-1}(K)$. Fix some $a \in X$, and let $\bar{a} = \sigma^{-1}(a)$. Let $\delta = X \cap \omega_1 = \omega_1^N$, and let $i < \omega_1$ be such that $\delta \in D_i$. Applying Lemma 3.29 to the sequence $\langle S_{\kappa,i} \mid \kappa \in K \rangle$, there is a $\sigma' : \bar{N} \rightarrow N$ with $\sigma'(\bar{K}) = K$, and $\sigma'(\bar{a}) = \sigma(\bar{a})$, such that for every $\bar{\kappa} \in \bar{K}$, $\sup \sigma'(\bar{\kappa}) = \bar{S}_{\sigma(\bar{\kappa}),i}$. Now let $\bar{Y} = \text{ran}(\sigma')$. Then $\pi = \sigma' \circ \sigma^{-1} : X \rightarrow \bar{Y}$ is an isomorphism fixing $\sigma(\bar{a})$, and $\bar{Y} \cap H_\rho \subseteq S_{\kappa,i}$: since neither $\sigma$ nor $\sigma'$ move countable ordinals, we have that $\bar{Y} \cap \omega_1 = X \cap \omega_1 = \delta$. Now let $\kappa \in Y \cap K$. Let $\bar{\kappa} = \sigma'(\bar{\kappa})$. Since $\sigma'(\bar{K}) = K$, we have that $\bar{\kappa} \in \bar{K}$. Let $\bar{\kappa} = \sup \sigma'(\bar{\kappa})$. Then $\sigma'(\bar{\kappa}) = Y \cap \kappa$, and so, $\bar{\kappa} = \sup(Y \cap \kappa) \in S_{\kappa,i}$, as wished.

It is easy to see that the construction in the proof of Lemma 3.29 can be modified so as to obtain the version of the previous corollary in which “spread out” is replaced with “fully spread out.” The corollary can be made to be closer to Corollary 3.27 by adding the assumption of $\infty$-SC-SRP, because then the cardinal arithmetic requirements on $K$ are automatically satisfied.

**Corollary 3.32.** Assume $\infty$-SC-SRP. Let $K$ be a set of regular cardinals such that $\min(K) > 2^\omega$. Let $\vec{S} = \langle S_{\kappa,i} \mid \kappa \in K, i < \omega_1 \rangle$ be such that for every $\kappa \in K$ and every $i < \omega_1$, $S_{\kappa,i} \subseteq S_{\kappa}^\omega$ is stationary in $\kappa$. Let $\vec{D}_i \mid i < \omega_1 \rangle$ be a partition of $\omega_1$ into stationary sets, and let $\rho \geq \sup(K)$ be regular. Then the set

$$S = \{ M \in [H_\rho]^\omega \mid \forall \kappa \in M \cap K \forall i < \omega_1 \ (M \cap \omega_1 \in D_i \implies \sup(M \cap \kappa) \in S_{\kappa,i}) \}$$

is spread out.

**Proof.** The point is that under $\infty$-SC-SRP, we have that for any regular cardinal $\kappa > 2^\omega$, $\kappa^\omega = \kappa$, by Theorem 3.19 and Fact 3.15. Thus, Corollary 3.31 applies, completing the proof. □
Thus, under $\infty$-SC-SRP + CH, an even stronger version of Corollary 3.27 holds with “spread out,” and even “fully spread out,” in place of “projective stationary,” since it does not assume the partition of $\omega_1$ into stationary sets to be maximal. Here is the promised version of Theorem 3.28 for $\infty$-SC-SRP, and even SC-SRP:

**Theorem 3.33.** Assume $\infty$-SC-SRP. Let $K$ be a set of regular cardinals with $\min(K) > 2^{\omega_1}$. Then the conclusions of Theorem 3.28 hold: let $\vec{S} = \langle S_{\kappa,i} \mid \kappa \in K, i < \omega_1 \rangle$ be such that for every $\kappa \in K$ and $i < \omega_1$, $S_{\kappa,i}$ is a subset of $S^\kappa_\omega$ stationary in $\kappa$. For $\kappa \in K$, let $\vec{S}_\kappa = \langle S_{\kappa,i} \mid i < \omega_1 \rangle$. Then the sequence $\vec{T} = \langle e_{Tr}(\vec{S}_\kappa) \mid \kappa \in K \rangle$

is mutually stationary.

Thus, under the additional assumption of CH, we get the full conclusion of Theorem 3.28 from $\infty$-SC-SRP.

**Proof.** The point is that under $\infty$-SC-SRP, we have that for any regular cardinal $\kappa > 2^{\omega_1}$, $\kappa^{\omega_1} = \kappa$, by Theorem 3.19 and Fact 3.15. Thus, the assumptions on $K$ in Corollary 3.31 are satisfied. The theorem now follows by an argument exactly as in the proof of Theorem 3.28. \qed

The following result of Jensen [30] fits in here well. I recast it as a statement about mutual stationarity.

**Theorem 3.34** (Jensen). Assume that SCFA holds, and GCH holds below $\lambda$, an uncountable cardinal. Let $K \subseteq \lambda$ be a set of regular cardinals greater than $\omega_1$, and let $f : K \rightarrow \{\omega, \omega_1\}$. Then the sequence $\langle S^\kappa_{f(\kappa)} \mid \kappa \in K \rangle$ is mutually stationary.

The proof of this theorem uses the subcompleteness of an intricate forcing notion, developed in [29], that changes the cofinality of some regular cardinals to be countable, while preserving that others have uncountable cofinality. Clearly, this forcing is not countably distributive. It seems unlikely that in this theorem, SCFA can be replaced with SC-SRP, as the forcing notions of the form $P_S$ are countably distributive. This question is a fitting segue into the next section, in which I will explore stationary reflection principles that do not follow from fragments of SRP, and consequences of SCFA that don’t follow from SC-SRP, thus separating these assumptions.

4. Limitations and separations

I will now explore limitations on the extent to which the subcomplete fragment of SRP implies certain principles of stationary reflection, and I will develop some results going in the direction of separating the subcomplete fragment of SRP from SCFA. In the first subsection, I will focus on achieving such results in a general setting, but the results strongly suggest that the addition of CH should be made. Consequently, the last two subsections deal with this scenario.

4.1. The general setting. Here, I will explore a framework for obtaining limiting results, following the approach of Larson [35], originally in the setting of the full SRP. The idea is to start in a model of set theory $V$ in which an indestructible version of SRP holds, namely, SRP holds in $V$ and in any forcing extension of $V$ obtained by $\omega_2$-directed closed forcing. This indestructible form of SRP follows from MM. To show that SRP does not imply a statement $\varphi$, one then forces with
The property \( \varphi \) in this approach is usually a statement about stationary reflection, and so, the forcing \( \mathbb{P} \) usually adds a sequence of stationary sets that does not reflect in a certain way. The forcing \( \mathbb{T} \) is usually a forcing that destroys this counterexample to \( \varphi \) by destroying the stationarity of some of the sets in the sequence, that is, by shooting a club through the complement of some of these sets. Given a stationary and costationary subset \( A \) of some regular uncountable cardinal \( \kappa \), the forcing used is called \( \mathbb{T}_A \) (the forcing to “kill” \( A \)), and consists of closed bounded subsets of \( \kappa \) disjoint from \( A \), and ordered by end-extension. Larson \([33]\) Lemma 4.5] has analyzed when this forcing notion preserves generalized stationarity; see \([22]\) Lemma 4.3] for a proof of this exact formulation.

**Lemma 4.1.** Let \( \gamma > \omega_1 \) be regular, \( X \supseteq \gamma \) a set, \( A \subseteq \gamma \) stationary and \( S \subseteq [X]^\omega \) also stationary, such that \( \gamma \setminus A \) is unbounded in \( \gamma \) and \( \mathbb{T}_A \) is countably distributive (this is the case, for example, if \( A \subseteq S_\omega^\kappa \) and \( S_\omega^\kappa \setminus \gamma \) is stationary). Then the following are equivalent:

1. \( S \setminus \text{lifting}(A, [X]^\omega) \) is stationary.
2. \( \mathbb{T}_A \) preserves the stationarity of \( S \).
3. There is a condition \( p \in \mathbb{T}_A \) that forces that \( \dot{S} \) is stationary.

This leads to a characterization of when \( \mathbb{T}_A \) preserves projective stationarity as follows.

**Lemma 4.2.** Let \( \gamma > \omega_1 \) be regular, \( X \supseteq \gamma \) a set, \( A \subseteq \gamma \) stationary and \( S \subseteq [X]^\omega \) projective stationary, such that \( \gamma \setminus A \) is unbounded in \( \gamma \) and \( \mathbb{T}_A \) is countably distributive. Then the following are equivalent:

1. \( S \setminus \text{lifting}(A, [X]^\omega) \) is projective stationary.
2. \( \mathbb{T}_A \) preserves the projective stationarity of \( S \).
3. There is a condition \( p \in \mathbb{T}_A \) that forces that \( \dot{S} \) is projective stationary.

**Proof.** \( [1] \implies [2] \) Suppose \( G \subseteq \mathbb{T}_A \) is generic and \( S \) is not projective stationary in \( V[G] \). Then there is some stationary \( B \subseteq \omega_1 \) such that in \( V[G] \), \( S \cap \text{lifting}(B, [X]^\omega) \) is not stationary. Since \( \mathbb{T}_A \) is countably distributive, \( B \in V \) is stationary in \( V \). Since in \( V \), \( S \setminus \text{lifting}(A, [X]^\omega) \) is projective stationary, we know that \( (S \setminus \text{lifting}(A, [X]^\omega)) \cap \text{lifting}(B, [X]^\omega) \) is stationary. Note that this intersection is the same as \( (S \cap \text{lifting}(B, [X]^\omega)) \setminus \text{lifting}(A, [X]^\omega) \). So by Lemma 4.1, \( S \setminus \text{lifting}(B, [X]^\omega) \) is stationary in \( V[G] \), a contradiction.

\( [2] \implies [3] \) is trivial.

\( [3] \implies [1] \) Let \( p \in \mathbb{T}_A \) force that \( \dot{S} \) is projective stationary. Then, for every stationary \( B \subseteq \omega_1 \), \( p \) forces that \( S \setminus \text{lifting}(B, [X]^\omega) \) is stationary. By Lemma 4.1, this implies that \( (S \setminus \text{lifting}(B, [X]^\omega)) \setminus \text{lifting}(A, [X]^\omega) \) is stationary. That is, for every stationary \( B \subseteq \omega_1 \), \( (S \setminus \text{lifting}(A, [X]^\omega)) \cap \text{lifting}(B, [X]^\omega) \) is stationary, which means that \( S \setminus \text{lifting}(A, [X]^\omega) \) is projective stationary, as wished. \( \square \)
To formulate some sample applications of these methods, let me recall the following principles of stationary reflection. The simultaneous reflection principles are well-known, see [9]. The first diagonal version was originally introduced in Fuchs [20], and its variations come from Fuchs & Lambie-Hanson [22].

**Definition 4.3.** Let $\lambda$ be a regular cardinal, let $S \subseteq \lambda$ be stationary, and let $\kappa < \lambda$.

The **simultaneous reflection principle** $\text{Refl}(\kappa, S)$ says that whenever $\vec{S} = \langle S_i \mid i < \kappa \rangle$ is a sequence of stationary subsets of $S$, then $\vec{S}$ has a simultaneous reflection point (see Def. 3.13).

The **diagonal reflection principle** $\text{DSR}(\kappa, S)$ says that whenever $\langle S_{\alpha,i} \mid \alpha < \lambda, i < j_\alpha \rangle$ is a sequence of stationary subsets of $S$, where $j_\alpha < \kappa$ for every $\alpha < \lambda$, then there are an ordinal $\gamma < \lambda$ of uncountable cofinality and a club $F \subseteq \gamma$ such that for every $\alpha \in F$ and every $i < j_\alpha$, $S_{\alpha,i} \cap \gamma$ is stationary in $\gamma$.

The version of the principle in which $j_\alpha \leq \kappa$ is denoted $\text{DSR}(\kappa, S)$.

If $F$ is only required to be unbounded, then the resulting principle is called $\text{uDSR}(\kappa, S)$, and if it is required to be stationary, then it is denoted $\text{sDSR}(\kappa, S)$.

These principles can be viewed as different ways of generalizing the following reflection principle, due to Larson [35].

**Definition 4.4.** The principle $\text{OSR}_{\omega^2}$ (for “ordinal stationary reflection”) states that whenever $\vec{S} = \langle S_i \mid i < \omega^2 \rangle$ is a sequence of stationary subsets of $S_{\omega^2}$, there is an ordinal $\rho < \omega^2$ of uncountable cofinality which is a simultaneous reflection point of $\vec{S}_{\rho} \restriction \rho$.

The following fact shows that the principles introduced above indeed generalize $\text{OSR}_{\omega^2}$.

**Fact 4.5** (special case of [22, Lemma 2.4]). The following are equivalent:

1. $\text{uDSR}(\omega_1, S_{\omega^2})$
2. $\text{DSR}(\omega_1, S_{\omega^2})$
3. $\text{OSR}_{\omega_2}$

The result of Larson [35, Thm. 4.7] most relevant here is that if Martin’s Maximum is consistent, then it is consistent that SRP holds but $\text{OSR}_{\omega_2}$ fails. On the other hand, MM implies $\text{OSR}_{\omega_2}$. Hence, $\text{OSR}_{\omega_2}$ is a consequence of MM which is not captured by SRP, thus separating MM from SRP. The following lemma shows that, under the appropriate assumptions, the $\infty$-subcomplete fragment of SRP does not even imply $\text{Refl}(1, S_{\omega^2})$, giving a much stronger failure of reflection.

**Lemma 4.6.** Assume that SRP holds and continues to hold after $\omega_2$-directed closed forcing. Then there is an $\omega_2$-strategically closed forcing of size $\omega_2$ in whose extensions the following hold:

1. $\infty$-SC-SRP,
2. $2^\omega = \omega_2$,
3. there is a nonreflecting stationary subset of $S_{\omega^2}$.

**Proof.** Let $\mathbb{P}$ be the forcing to add a nonreflecting stationary subset of $S_{\omega^2}$ by closed initial segments. Since SRP holds, we have that $\omega_2^\omega = \omega_2$, and hence, the cardinality of $\mathbb{P}$ is $\omega_2$, and it is well-known that $\mathbb{P}$ is $\omega_2$-strategically closed. A generic filter for $\mathbb{P}$ may be identified with its union, which is a nonreflecting stationary subset of $S_{\omega^2}$. Let $A$ be such a generic set. $V[A]$ then has the desired properties, and only
property \( \{a\} \) needs to be verified. To see this, let me prove a general claim, which may be useful in other contexts as well.

(1) Suppose \( \omega_1 < \lambda \leq 2^\omega \), \( \lambda \) regular, and \( B \) is a stationary subset of \( S^\lambda_\omega \). Let \( \kappa \geq \lambda \) be regular, and let \( S \subseteq [H_\kappa]^\omega \) be spread out. Then \( S \cap \text{lifting}(B, [H_\kappa]^\omega) \) is projective stationary.

**Proof of (1).** Let \( D \subseteq \omega_1 \) be stationary, and let \( f : (H_\kappa)^{<\omega} \to H_\kappa \). We have to find an \( x \in S \) such that \( S \cap x \in D \), \( x \) is closed under \( f \) and \( \sup(x \cap \lambda) \in B \). To this end, let \( \theta \) witness that \( S \) is spread out. Let \( H_\theta \subseteq N = L_\theta^I \), where \( S, \theta, f \in N \) and \( \tau \) is a cardinal in \( L[I] \). Let \( \tau' = (\tau^+)_{L[I]} \), and let \( N' = L_{\tau'}^I \). Let \( x' \) be countable with \( N'|x' \prec N \) and \( S, \theta, f, \lambda \in x' \). Moreover, let \( x' \cap \omega_1 \in D \) and \( \sup(x' \cap \lambda) \in B \). This is possible by Fact 3.22. Let \( x = x' \cap L_\tau[I] \). Then \( x \) is full, and hence, since \( S \) is spread out, there is a \( y \) such that \( N|x \) is isomorphic to \( N|y \) via an isomorphism \( \pi \) which fixes \( f \), and such that \( \bar{y} = y \cap H_\kappa \in S \). But since \( \lambda \leq 2^\omega \), \( \pi \) is the identity on \( \lambda \) (see the paragraph before Observation 2.32), so that \( \bar{y} \) is as wished: \( \bar{y} \cap \omega_1 = x \cap \omega_1 \in D \), \( \sup(\bar{y} \cap \lambda) = \sup(x \cap \lambda) \in B \), \( \bar{y} \in S \), and since \( f = \pi(f) \in y \), \( \bar{y} \) is closed under \( f \).

Now, working in \( V[A] \), \( A \) is a nonreflecting stationary subset of \( S^{<\omega}_\omega \). It follows that \( B = S^{<\omega}_\omega \setminus A \) is stationary. Hence, by Claim (1) \( S \cap \text{lifting}(B, [H_\kappa]^\omega) = S \setminus \text{lifting}(A, [H_\kappa]^\omega) \) is projective stationary. By Lemma 4.2 it follows that the forcing \( T_A \) preserves the projective stationarity of \( S \).

Now it is well-known that \( \mathbb{P} \ast T_A \) is forcing equivalent to an \( \omega_2 \)-directed closed forcing of size \( \omega_2 \), so that if we let \( H \) be generic for \( T_A \) over \( V[G] \), then SRP holds in \( V[G][H] \), where \( S \) is projective stationary. Working in \( V[G][H] \), let \( \langle y_\alpha \mid \alpha < \omega_1 \rangle \) be a continuous \( \in \)-chain through \( S \upharpoonright [H^\omega_\kappa[G][H]]^\omega \). Then letting \( x_\alpha = y_\alpha \cap H^\kappa[G], \) it follows that \( \bar{x} \) is a continuous \( \in \)-chain through \( S \), and \( \bar{x} \in V[G] \), since \( T_A \) is \( \omega_2 \)-distributive in \( V[G] \).

Note that it was crucial in the proof of (1) that \( \lambda \leq 2^\omega \), and the case \( \lambda = \omega_2 \) was what was used in the remainder of the proof. Thus, we are in the funny situation that if we want \( \infty \text{-SC-SRP} \) to be *similar* to SRP, in that it should yield consequences like \( \text{Ref}(\omega_1, S^{<\omega}_\omega) \), for example, then we should add the assumption that CH holds, which *contradicts* SRP. In fact, already Observation 2.32 was a clear indication that one should add CH to \( \infty \text{-SC-SRP} \) in order to make it stronger.

I also have to point out that the previous lemma does *not* separate \( \infty \text{-SC-SRP} \) from \( \infty \text{-SCFA} \). In fact, Hiroshi Sakai observed that methods of Sean Cox can be used to show that \( \infty \text{-SCFA} + 2^\omega = \omega_2 \) is consistent with the failure of \( \text{Ref}(1, S^{<\omega}_\omega) \) as well, and more, for example, \( \infty \text{-SCFA} \), if consistent, is consistent with \( \Box \omega_1 \). The details of the argument, and variations of it, have been worked out by Corey Switzer (forthcoming).

Thus, Lemma 1.6 provides a fairly strong *limitation* of \( \infty \text{-SC-SRP} \), but fails to *separate* it from \( \infty \text{-SCFA} \). However, it is possible to obtain a separating result as follows. The first fact I need is that for a regular cardinal \( \kappa \), \( \text{DSR}(\omega_1, S^{<\omega}_{\omega_1}) \) follows from Martin’s Maximum if \( \kappa > \omega_1 \), and also from \( \text{SCFA} \), for \( \kappa > 2^\omega \), see [20].

Second, the principle does not follow from SRP. In fact:

**Theorem 4.7** ([Fuchs & Lambie-Hanson [22 Thm. 4.4]]) Let \( \kappa > \omega_2 \) be regular, and suppose that SRP holds and continues to hold in any forcing extension obtained
by \( \kappa \)-directed closed forcing. Then there is a \( \kappa \)-strategically closed forcing notion that produces forcing extensions in which

1. SRP continues to hold, but
2. \( \text{uDSR}(1, S_\omega^\kappa) \) fails.

Thus, a model as in the previous theorem will satisfy \( \infty \)-\( \text{SC} \)-\( \text{SRP} \) (since it even satisfies the full SRP), but not SCFA, since \( \kappa \) is regular and greater than \( \omega_2 = 2^\omega \) in that model, so if SCFA held, then this would imply \( \text{DSR}(\omega_1, S_\omega^\kappa) \) by the abovementioned fact, contradicting that even \( \text{uDSR}(1, S_\omega^\kappa) \) fails. Thus:

**Fact 4.8.** Assuming the consistency of MM, \( \infty \)-\( \text{SC} \)-\( \text{SRP} \) does not imply SCFA.

While this is in a sense a satisfying separation result, I view the fact that \( \infty \)-\( \text{SC} \)-\( \text{SRP} \)(\( \omega_2 \)) is trivial if \( 2^\omega \geq \omega_2 \), and that \( \infty \)-\( \text{SC} \)-\( \text{SRP} \), and even \( \infty \)-\( \text{SCFA} \), do not imply \( \text{Refl}(1, S_\omega^{\omega_2}) \) if CH fails, as strong indications that these axioms should be augmented with the assumption of CH. But in the model that witnesses the separation fact just stated, we have that \( 2^\omega = \omega_2 \), so I have not separated \( \infty \)-\( \text{SC} \)-\( \text{SRP} \) + CH from \( \infty \)-\( \text{SCFA} \). Since these are the axioms of the main interest, I will focus on them for the remainder of this article. The goal result would be that the answer to the following question is no:

**Question 4.9.** Does \( \infty \)-\( \text{SC} \)-\( \text{SRP} \) + CH imply \( \text{uDSR}(1, S_\omega^\kappa) \), for any regular \( \kappa > \omega_1 \), or any of the diagonal reflection principles?

Note that answering this question in the negative would strengthen the conclusion of Theorem 4.7. The reason why I am hopeful that this might be the case is that the assumption of CH might replace the assumption that the nonstationary ideal in \( \omega_1 \)-dense in the following.

**Corollary 4.10** (Fuchs & Lambie-Hanson [22, Cor. 4.7]). Suppose that SRP holds and continues to hold in any forcing extension obtained by an \( \omega_2 \)-directed closed forcing notion. Assume furthermore that the density of the nonstationary ideal on \( \omega_1 \) is \( \omega_1 \). Then there is an \( \omega_2 \)-strategically closed forcing notion which produces forcing extensions where

1. SRP continues to hold, but
2. \( \text{uDSR}(1, S_\omega^{\omega_2}) \) fails.

However, there are obstacles to obtaining versions of Theorem 4.7 or the corollary just mentioned for \( \infty \)-\( \text{SC} \)-\( \text{SRP} \) in the context of CH. The main problem is to find a version of the Preservation Lemma 4.2 for spread out sets rather than for projective stationarity.

### 4.2. The CH setting: a less canonical separation

I will now move on to a partial separation result which may be cause for optimism that the answer to Question 4.9 is negative. It concerns the fragment of \( \infty \)-\( \text{SC} \)-\( \text{SRP} \) that says that SRP holds for all the spread out sets shown to be spread out in this article. These are the ones from Subsection 3.3. Since this fragment of SRP does not correspond to a forcing class, I don’t consider it to be canonical, hence the title of the present subsection.

**Definition 4.11.** Let \( \rho \) be regular, and let \( K \subseteq \rho \) be a set of regular cardinals such that \( \min(K) > \omega_1 \). Let \( S = \langle S_{\kappa,i} \mid \kappa \in K, i < \omega_1 \rangle \) be such that for every \( \kappa \in K \) and every \( i < \omega_1 \), \( S_{\kappa,i} \subseteq S_\omega^\kappa \) is stationary in \( \kappa \). Let \( \langle D_i \mid i < \omega_1 \rangle \) be a partition
of $\omega_1$ into stationary sets, and let $\rho \geq \sup(K)$ be regular. Let’s call $\langle \vec{D}, \vec{S} \rangle$ a $K$-correspondence, and define
\[
lifting(\vec{D}, \vec{S}, [H_\rho]^\omega) = \{ x \in [H_\rho]^\omega \mid \forall \kappa \in x \cap K \forall i < \omega_1 \}
\]
\[
(\exists x, \omega_1 \in D_i \implies \sup(x \cap \kappa) \in S_{\kappa,i}) \}.
\]
Let
\[
S^+(\rho) = \{ \text{lifting}(\langle \vec{D}, \vec{S}, [H_\rho]^\omega \rangle \cap C \mid \langle \vec{D}, \vec{S} \rangle \text{ is a } K\text{-correspondence}
\]
for some $K \subseteq \rho$, and $C \subseteq [H_\rho]^\omega$ is club}.\]

Let’s write $\text{SRP}(S^+)$ for the statement that $\text{SRP}(S^+(\rho))$ holds for every regular $\rho > \omega_1$.

**Observation 4.12.** It follows from the results of the previous subsections that:

1. If $\text{SRP}(S^+) + \text{CH}$ implies $\text{SRP}(S^+)$.
2. If $\text{SRP}(S^+) + \text{CH}$ holds, then for all regular $\kappa > \omega_1$, $\kappa^{\omega_1} = \kappa$, and hence, every set in $S^+(\rho)$, for $\rho > \omega_1$, is spread out.

The assumptions of the following theorem are implied by $\text{SCFA} + \text{CH}$; see Fuchs & Rinot [23].

**Theorem 4.13.** Assume that $\text{SRP}(S^+)$ holds in $V$ and in any forcing extension obtained by a $\lambda$-directed closed forcing, and that $\text{CH}$ is true. Then there is a $\lambda$-strategically closed forcing in whose forcing extensions

1. $\text{SRP}(S^+)$ holds, yet
2. $\text{uDSR}(1, S^+) \text{ fails}$.

**Remark 4.14.** I recommend reading the proof with Question 4.13 in mind. The problem is the preservation of an arbitrary spread out set without knowing that it belongs to some $S^+(\rho)$.

**Proof.** The forcing notion in question is $\mathbb{P}$, the forcing to add a counterexample to $\text{uDSR}(1, S^+) \text{ used in the proof of [22] Theorem 3.10}$, where it is shown that $\mathbb{P}$ is $\omega_2$-strategically closed (see claim 3.11 in the proof). Let $G$ be generic for $\mathbb{P}$. In $V[G]$, there is a sequence $\vec{A} = \langle A_{\alpha} \mid \alpha < \omega_2 \rangle$ which witnesses the failure of $\text{uDSR}(1, S^+)$. That is, for every $\alpha < \omega_2$ of uncountable cofinality, the set $\{ \xi < \alpha \mid A_{\xi} \cap \alpha \text{ is stationary in } \alpha \}$ is bounded in $\alpha$. Thus, I will be done if I can show that $V[G]$ satisfies $\text{SRP}(S^+)$. To this end, let $S \subseteq [H_\lambda]^\omega \in S^+(\rho)$, for some regular $\rho > \omega_1$. Let $\vec{D}, \vec{S}, C$ witness this, that is, $\vec{D} = \langle D_i \mid i < \omega_1 \rangle$ is a partition of $\omega_1$ into stationary sets, $\vec{S} = \langle S_{\kappa,i} \mid \kappa \in K, i < \omega_1 \rangle$, where $K \subseteq \rho$ is a set of regular cardinals greater than $\omega_1$, $C \subseteq [H_\rho]^\omega$ is club and $S = \text{lifting}(\vec{D}, \vec{S}, [H_\rho]^\omega) \cap C$. For $\beta < \lambda$, let $A_{\geq \beta} = \bigcup_{\beta \leq \alpha < \omega_2} A_{\alpha}$, and let $T_{\beta}$ be the forcing to shoot a club through the complement of $A_{\geq \beta}$. By Claim 3.13 of the proof of [22] Theorem 3.9], the forcing $\mathbb{P} \ast T_{\geq \beta}$ has a dense subset that’s $\omega_2$-directed closed and has size $\omega_2$ in $V$. It is used here that $\omega_2^{\omega_2} = \omega_2$, which follows from $\text{SRP}(S^+) + \text{CH}$. Clearly then, $\mathbb{P} \ast T_{\geq \beta}$ preserves cofinalities.

Let me assume for a second that $\omega_2 \in K$. By Claim 3.13 of the aforementioned proof, for every $i < \omega_1$, there is a $\beta_i < \omega_2$ such that $S_{\omega_2,i} \setminus A_{\geq \beta_i}$ is stationary. Let $\beta = \sup_{i < \omega_1} \beta_i$. Then $\beta < \omega_2$, and for every $i < \omega_1$, $S_{\omega_2,i} \setminus A_{\geq \beta}$ is stationary, which
means that forcing with $T_\beta$ preserves the stationarity of each $S_{\omega_2,i}$, see [22, Lemma 3.7.(2)].

If $\omega_2 \notin K$, then let $\beta = 0$.

Now let $H$ be $T_\beta$-generic over $V[G]$. Since $P \ast T_\beta$ has a dense subset that’s $\omega_2$-directed closed, it follows from our indestructible $\text{SRP}(S^+)$ assumption in $V$ that $\text{SRP}(S^+)$ holds in $V[G][H]$. Since $P \ast T_\beta$ has an $\omega_2$-directed closed subset, it adds no sequences of ground model sets of length less than $\omega_2$. In $V[G][H]$, it is still the case that $C$ is a club subset of $[H^V_{\omega_2}]^{\omega}$, and it is still the case that $\langle \bar{D}, \bar{S} \rangle$ is a correspondence: $\bar{D}$ obviously is still a partition of $\omega_1$ into stationary sets. Since $P \ast T_{\geq \beta}$ preserves cofinalities, $K$ is still a set of regular cardinals greater than $\omega_1$. Now, for $\kappa \in K$ and $i < \omega_1$, $S_{\kappa,i}$ is still a stationary subset of $S^+_{\kappa,i}$ in the case where $\kappa = \omega_2$, this is by our choice of $\beta$, and if $\kappa > \omega_2$, then $T_\beta$ preserves the stationarity of $S_{\kappa,i}$ because it is $\kappa$-c.c.; it has size $\omega_2 < \kappa$.

Let $C^* = C \upharpoonright [H^V_{\omega_2}]^{\omega} - so$ $C^*$ contains a club $C'$. In $V[G][H]$, let $S^* = \text{lifting}(\bar{D}, \bar{S}, [H^V_{\omega_2}]^{\omega}) \cap C'$. Then $S^* \in S^+(\rho)$ in $V[G][H]$, so by $\text{SRP}(S^+)$ in $V[G][H]$, there is a continuous $\varepsilon$-chain $\langle x'_i \mid i < \omega_1 \rangle$ through $S^*$. But then, for every $i < \omega_1$, $x_i = x'_i \cap H^V_{\omega_2} \in S$. This is because $x'_i \in C' \subseteq C \upharpoonright [H^V_{\omega_2}]^{\omega}$, so that $x_i \in C$, and because $x'_i \in \text{lifting}(\bar{D}, \bar{S}, [H^V_{\omega_2}]^{\omega})$, if we let $j = x'_i \cap \omega_1$, then $j = x_i \cap \omega_1$, and further, if $\kappa \in K \cap x_i$, then $\kappa \in K \cap x'_i$, so that $\sup x_i \cap x_i = \sup x'_i \cap \kappa \in S_{\kappa,j}$. Now the sequence $\langle x_i \mid i < \omega_1 \rangle$ already exists in $V[G]$, since $T_\beta$ is $\omega_2$-distributive in $V[G]$.

Thus, $V[G]$ satisfies $\text{SRP}(S^*)$ but not $u\text{DSR}(1, S^+_{\kappa})$, as desired. \hfill \Box

In particular, it is not the case that $\text{SFP}_\lambda + CH$ implies $u\text{DSR}(1, S^+_{\kappa})$, for regular $\lambda > \omega_1$. This is because $\text{SRP}(S^+)$ does imply $\text{SFP}_\lambda$, and because of the previous theorem.

### 4.3. The CH setting: a canonical separation at $\omega_2$.

In the present subsection, I work with subcompleteness rather than $\infty$-subcompleteness. The goal is to separate, to some degree, the subcomplete forcing axiom from the subcomplete fragment of $\text{SRP}$ in the presence of the continuum hypothesis. The idea is to take a consequence of $\text{SCFA}$ that is obtained using a subcomplete forcing that is not countably distributive (as suggested by the discussion after Theorem 3.34), and to argue that it does not follow from the subcomplete fragment of $\text{SRP}$. The forcing in question is going to be Namba forcing, changing a regular cardinal to have countable cofinality. The first ingredient I will need is an iteration theorem for the subclass of subcomplete forcing notions consisting of those that preserve uncountable cofinalities. Thus, this class excludes Namba forcing.

**Definition 4.15.** A forcing notion $P$ is uncountable cofinality preserving if for every ordinal $\varepsilon$ of uncountable cofinality, $\Vdash_P \"\varepsilon \ has \ uncountable \ cofinality.\"

In the proof of the iteration theorem, I will use the Boolean algebraic approach to forcing iterations and to revised countable support, as described in [33]. An extensive account of the method is the manuscript [38], which also contains a proof of the following fact, originally due to Baumgartner, see [38, Theorem 3.13]:

**Fact 4.16.** Let $\langle \mathbb{B}_i \mid i < \lambda \rangle$ be an iteration such that for every $\alpha < \lambda$, $\mathbb{B}_\alpha$ is $<\lambda$-c.c., and such that the set of $\alpha < \lambda$ such that $\mathbb{B}_\alpha$ is the direct limit of $\mathbb{B}_\alpha$ is stationary. Then the direct limit of $\mathbb{B}_i$ is $<\lambda$-c.c.
I will use the following iteration theorem in the separation result I am working towards, but it may be of independent interest as well.

**Theorem 4.17.** Let \( \langle B_i \mid i \leq \delta \rangle \) be an RCS iteration of complete Boolean algebras such that for all \( i + 1 \leq \alpha \), the following hold:

1. \( B_i \neq B_{i+1} \),
2. \( \Vdash_{B_i} (B_{i+1}/G_{B_i} \text{ is subcomplete and uncountable cofinality preserving}) \),
3. \( \Vdash_{B_{i+1}} (\delta(B_i) \text{ has cardinality at most } \omega_1) \).

Then for every \( i \leq \delta \), \( B_i \) is subcomplete and uncountable cofinality preserving.

**Proof.** I will have to use some basic facts about iterated forcing with complete Boolean algebras and revised countable support. I will state these facts as I need them. The basic setup is that \( \langle B_i \mid i \leq \delta \rangle \) is a tower of complete Boolean algebras, with projection functions \( h_{j,i} : B_j \rightarrow B_i \) for \( i \leq j \leq \delta \) defined by \( h_{j,i}(b) = \bigwedge_{i \leq j} \{ a \in B_i \mid b \leq B_i a \} \). Since for \( i \leq j_0 \leq j_1 \leq \delta \), \( h_{j_1,i} \upharpoonright B_{j_0} = h_{j_0,i} \). I’ll just write \( h_i \) for \( h_{\delta,i} \), so that for all \( i \leq j \leq \delta \), \( h_{j,i} = h_i | B_j \).

I claim that:

- for every \( h < \delta \), if \( G_h \) is \( B_h \)-generic over \( V \), then in \( V[G_h] \), for every \( i \in [h, \delta] \), \( B_i/G_h \) is subcomplete and uncountable cofinality preserving.

Jensen’s proofs show that in this situation, \( B_i/G_h \) is subcomplete (see [34, §2, Thm. 1, pp. 3-24]), so that I can focus on the preservation of uncountable cofinality.

If not, let \( \delta \) be a minimal such that there is an iteration of length \( \delta \) that forms a counterexample.

Since the successor case is trivial, let me focus on the case that \( \delta \) is a limit ordinal. Let \( \varepsilon \) be an ordinal of uncountable cofinality in \( V[G_h] \). Note that by minimality of \( \delta \), this is equivalent to saying that \( \varepsilon \) has uncountable cofinality in \( V \). I will show that in \( V[G_h] \), \( B_\delta/G_h \) still forces that \( \varepsilon \) has uncountable cofinality.

**Case 1:** there is an \( i < \delta \) such that \( \text{cf}^{V[G_h]}(\varepsilon) \leq \delta(B_i) \).

Then by (3) in \( V[G_h] \), \( \Vdash_{B_{i+1}/G_h} \text{cf}(\varepsilon) \leq \omega_1 \). But by minimality of \( \delta \), we also know that \( \Vdash_{B_{i+1}} \text{cf}(\varepsilon) \geq \omega_1 \). Thus, \( B_{i+1}/G_h \) forces over \( V[G_h] \) that the cofinality of \( \varepsilon \) is \( \omega_1 \). But the tail of the iteration is subcomplete, and hence it preserves \( \omega_1 \). It follows that the cofinality of \( \varepsilon \) stays uncountable in \( V[G_h][B_\delta/G_h] \).

**Case 2:** case 1 fails. So for all \( i < \delta \), \( \text{cf}^{V[G_h]}(\varepsilon) > \delta(B_i) \).

Let \( \kappa = \text{cf}^{V[G_h]}(\varepsilon) \). Note that for \( i < \delta \), \( B_i \) is \( \delta(B_i)^+ \)-c.c., so since \( \kappa > \delta(B_i) \), it follows that \( \kappa \) is a regular uncountable cardinal greater than \( \delta(B_i) \) in \( B_\kappa \). We may also assume that \( \kappa > \omega_1 \), for if \( \kappa = \omega_1 \), then it will still have uncountable cofinality in \( V[G_h][B_\delta/G_h] \), since \( B_\delta/G_h \) is subcomplete in \( V[G_h] \) and hence preserves \( \omega_1 \), as in case 1.

**Case 2.1:** there is an \( i < \delta \) such that \( \text{cf}^{V[G_h]}(\delta) \leq \delta(B_i) \).

Then, since \( B_{i+1} \) collapses \( \delta(B_i) \) to \( \omega_1 \), it follows that in \( V[G_h][B_{i+1}/G_h] \), \( \delta \) has cofinality at most \( \omega_1 \). For notational simplicity, let me pretend that \( h = 0 \), so that I can write \( V[B_{i+1}] \) in place of \( V[G_h][B_{i+1}/G_h] \), for example. So from what I said above, \( \kappa \) is a regular uncountable cardinal in what we call \( V \) now, and it is greater than each \( \delta(B_j) \). So it suffices to show that \( B_\delta \) preserves the fact that \( \kappa \) has uncountable cofinality. I’m using here that the tail of the iteration in \( V[G_h] \) is a revised countable support iteration.

Towards a contradiction, let \( \tilde{f} \) be a \( B_\delta \)-name, and let \( a_0 \in B_\delta \) be a condition such that \( a_0 \) forces that \( \tilde{f} \) is a function from \( \omega \) to \( \kappa \) whose range is unbounded in
κ. I will find a condition extending α₀ that forces that the range of ² is bounded in κ, a contradiction.

Note that if cf(δ) = ω₁, then for every i < δ, ||Bi, cf(δ) = ω₁, as Bᵢ preserves ω₁. Thus, B₁ is the direct limit of B⁺δ, that is, {union}<i<δ Bᵢ is dense in B⁺δ in this case. Let me denote this dense set by X.

If, on the other hand, cf(δ) = ω, then since B⁺ is an RCS iteration, the set \{\bigwedge<i<δ tᵢ | tᵢ ∈ B⁺δ\} is dense in B⁺δ. Here, t is a thread in B⁺δ if for all i < j < δ, 0 ≠ tᵢ = tₗ(tⱼ). In case cf(δ) = ω, let X be that dense subset of B⁺δ. For more background on threads in RCS iterations, I refer the reader to p. 124.

Let π : ω₁ → δ be cofinal, with π(0) = 0.

Let N = L⁺δ with \(H₀ \cup \kappa + 1 \subseteq N\), where θ verifies the subcodelteness of each Bᵢ, for i ≤ δ and for each Bⱼ/Gᵢ whenever i < j < δ and Gᵢ is Bᵢ-generic. Let \(S = \langle κ, ε, δ, B, f, a₀, π \rangle\). Let σ₀ : N ↪ N, where N is transitive, countable and full, and S ∈ ran(σ₀). Let σ₀(S) = S, and let \(S = \langle \tilde{κ}, \tilde{ε}, \tilde{δ}, \tilde{B}, \tilde{f}, \tilde{a₀}, \tilde{π} \rangle\). Let \(\tilde{κ} = sup σ₀^{<κ} < κ\), and let us also fix an enumeration \(\tilde{N} = \{e_n \mid n < ω\}\). Let \(\tilde{G} \subseteq \tilde{B}⁺δ\) be generic over \(\tilde{N}\), with \(\tilde{a₀} \in \tilde{G}\).

Let \(n < ω\) be a sequence of ordinals \(\nu_n < ω⁺\) such that if we let \(\gamma_n = \tilde{π}(\nu_n)\), it follows that \(\langle \gamma_n \mid n < ω\rangle\) is cofinal in \(δ\), and such that \(v₀ = 0\), so that \(\gamma₀ = 0\). Hence, letting \(\gamma_n = σ₀(\gamma_n)\), we have that \(sup_{n < ω} \gamma_n = sup ran(σ₀ ∩ δ) = δ\). Moreover, whenever \(σ' : \tilde{N} ↪ N\) is such that \(σ'(\tilde{π}) = π\), it follows that for every n < ω, \(σ'(\gamma_n) = γ_n = π(ν_n)\), since \(σ'(\tilde{π}) ν_n = σ'(\tilde{π}) ν_n = π(ν_n)\).

By induction on n < ω, construct sequences \(\langle σ_n \mid n < ω \rangle, \langle c_n \mid n < ω \rangle\), with \(c_n \in B⁺γ_n\), \(δ_n \in V^{B⁺γ_n}\), such that for every n < ω, c_n forces the following statements with respect to B⁺γ_n:

1. \(σ_n : \tilde{N} ↪ \tilde{N}\),
2. \(σ_n(\tilde{S}) = \tilde{S}\), and for all k < n, \(σ_n(e_k) = \tilde{σ}_k(\tilde{e}_k)\),
3. \(σ_n(\tilde{G} \cap B⁺γ_n) \subseteq B⁺γ_n\),
4. \(sup σ_n^{<κ} = \tilde{κ}\),
5. \(c_{n-1} = h_{γ_n-1}(c_n)\) (for n > 0).

To start off, in the case n = 0, we set \(c₀ = \perp, σ₀ = \tilde{σ}_0\).

Now suppose \(\langle σ_n \mid n ≤ n \rangle, \langle c_m \mid m ≤ n \rangle\) have been constructed, so that the above conditions are satisfied so far. Let G⁺γᵢ be B⁺γᵢ-generic with \(cᵢ \in G⁺γᵢ\), and work in \(V[G⁺γᵢ]\) temporarily. Let \(σ_n = σ_n^{G⁺γᵢ}\). Then \(σ_n\) extends to \(σ_n^{*} : \tilde{N}[G⁺γ_n] ↪ N[G⁺γ_n]\) such that \(σ_n^{*}(G⁺γ_n) = G_n\). Since \(θ\) verifies the subcodelteness of \(B' = B⁺γₙ₊₁/G⁺γₙ\), and since \(N[G⁺γ_n]\) is full, there is a condition \(c' \in (B')⁺\) such that whenever \(G'\) is \(B'\)-generic in \(V[G⁺γ_n]\) with \(c' \in G'\), there is a \(σ' : \tilde{N}[G⁺γ_n] ↪ N[G⁺γ_n]\) such that \(σ'(G⁺γ_n) = G⁺γ_n, σ'(\tilde{S}) = S\) and \(σ'(\tilde{e}_k) = σ_n^{*}(\tilde{e}_k) = σ_n(\tilde{e}_k)\) for k ≤ n, \(σ'(\tilde{G} \cap B⁺γ_n) \subseteq G'\), where \(G' = G⁺γₙ₊₁/G⁺γₙ\), and \(sup(σ')^{<κ} = \tilde{κ} = sup(σ^{*})^{<κ}\). The point is that \(κ > δ(B⁺γₙ₊₁)\), so that the suprema condition can be employed in order to ensure this last point.

Since the situation described in the previous paragraph arises whenever \(G⁺γ_n\) is generic with \(c_n \in G⁺γ_n\), it is forced by \(c_n\), and there are B⁺γₙ-names \(c', \tilde{σ}_{n+1}\) for the condition \(c'\) and the restriction of the embedding \(σ'\) to \(\tilde{N}\). We may choose the name \(c'\) in such a way that \(\|B⁺γ_n \in \tilde{G} \cap B⁺γ_n\), and \(c_n = [c' \neq 0]_{B⁺γ_n}\). Namely, given the original \(c'\) such that \(c' \in (\tilde{G}⁺γₙ₊₁/G⁺γₙ)⁺\) and all the other
statements listed above, there are two cases: if $c_n = 1_{B_{\gamma_n}}$, then since $c_n \leq [\gamma' \neq 0]$, it already follows that $c_n = [\gamma' \neq 0]$. If $c_n < 1_{B_{\gamma_n}}$, then let $\dot{e} \in V^{B_{\gamma_n}}$ be a name such that $\models_{B_{\gamma_n}} \dot{e} = 0_{\dot{B}_{\gamma_{n+1}} / G_{\dot{B}_{\gamma_n}}}$, and mix the names $\dot{e}'$ and $\dot{e}$ to get a name $\dot{d}'$ such that $c_n \models_{B_{\gamma_n}} \dot{d}' = \dot{e}'$ and $\neg c_n \models_{B_{\gamma_n}} \dot{d}' = \dot{e}$. Then $\dot{d}'$ is as desired. Clearly, $\models_{B_{\gamma_n}} \dot{d}' \in \dot{B}_{\gamma_{n+1}} / G_{\dot{B}_{\gamma_n}}$. Since $c_n \models_{B_{\gamma_n}} \dot{d}' = \dot{e}'$, it follows that $c_n \leq [\dot{d}' \neq 0]$, and since $\neg c_n \models_{B_{\gamma_n}} \dot{d}' = \dot{e}$, it follows that $\neg c_n \leq [\dot{d}' = 0] = [\dot{d}' \neq 0]$, so $[\dot{d}' \neq 0] \leq c_n$. So we could replace $\dot{e}'$ with $\dot{d}'$.

So let us assume that $\dot{e}'$ already has this property, that is, $c_n = [\dot{e}' \neq 0]$. Then, by [33] §0, Fact 4 there is a unique $c_{n+1} \in B_{\gamma_{n+1}}$ such that $\models_{B_{\gamma_n}} \dot{e}_{n+1} / G_{\dot{B}_{\gamma_n}} = \dot{e}'$, and it follows by [33] §0, Fact 3] that

$$h(c_{n+1}) = [\dot{e}_{n+1} / G_{\dot{B}_{\gamma_n}} \neq 0]_{B_{\gamma_n}} = [\dot{e}' \neq 0]_{B_{\gamma_n}} = c_n$$

as wished.

This finishes the construction of $\langle \sigma_n | n < \omega \rangle$ and $\langle c_n | n < \omega \rangle$.

Now, the sequence $\langle c_n | n < \omega \rangle$ is a thread, and so, $c = \bigwedge_{n<\omega} c_n \in B_\gamma^\ast$. Let $G$ be $B_\gamma$-generic with $c \in G$. In $V[G]$, let

$$\sigma = \bigcup_{n<\omega} \sigma_n^{G \cap B_{\gamma_n}} \cap \{e_0, \ldots, e_n\}.$$ 

Jensen’s arguments then show that $\sigma : \check{N} \prec N$, and $\sigma^* G \subseteq G$. For the latter, we can argue as in [33] p. 141, proof of (d): clearly, $\sigma^* G \cap B_{\gamma_n} \subseteq G$, for every $n < \omega$, since if $\dot{a} \in G \cap B_{\gamma_n}$, then for some $m \geq n$, $\sigma(a) = \sigma_m(a) \in G \cap B_{\gamma_m} \subseteq G$ (letting $a = e_k$, this is true whenever $m \geq \max(n, k))$. If $\operatorname{cf}(\delta) = \omega_1$, then this implies directly that $\sigma^* G \subseteq G$, because then, in $N$, $B_\delta$ is the direct limit of $\check{B} \cap \delta$, so $\bigcup_{\delta < \omega} B_{\delta}$ is dense in $B_\delta$. So if $\dot{a} \in G$, we may assume that $\dot{a} \in G \cap B_{\gamma_n}$, for some $n < \omega$, so that $a \in G \cap B_{\gamma_n}$.

If $\operatorname{cf}(\delta) = \omega$, that is, in $N$, $\operatorname{cf}(\check{\delta}) = \omega$, then $B_\delta$ is the inverse limit of $\langle B_i | i < \delta \rangle$. Hence, letting $\check{a} \in G$, we may assume that $\check{a} = \bigwedge_{i < \delta} \check{a}_i$, where $\langle \check{a}_i | i < \check{\delta} \rangle$ is a thread in $\langle B_i | i < \check{\delta} \rangle$, since the set of such conditions is dense in $B_{\check{\delta}}$. Let $\sigma(\check{a}) = \check{a} = \langle a_i | i < \check{\delta} \rangle$. Then $\check{a}$ is a thread in $\langle B_i | i < \delta \rangle$. Moreover, for each $n < \omega$, $\sigma(\check{a}_{\gamma_n}) = a_{\gamma_n} \in G$. Thus, $\sigma(\check{a}) = \bigwedge_{n<\omega} a_{\gamma_n} \in G$, by the completeness of $G$ (since $\langle a_{\gamma_n} | n < \omega \rangle \in V$, as $\check{a} \in N \subseteq V$ and $\langle \gamma_n | n < \omega \rangle \in V$).

Thus, $\sigma$ lifts to an elementary embedding $\sigma^* : N[G] \prec N[G]$. Note that $\check{a}_0 \in G$, and so, $a_0 = \sigma^*(\check{a}_0) \in G$. Moreover, $\sigma^*(\check{\kappa}) \subseteq \check{\kappa}$, because if $\check{\xi} = e_k$, then for some $n < \omega$, $\check{\xi} = e_k$, and so, $\sigma(\check{\xi}) = \sigma(e_n) = \sigma_n(e_n) = \sigma_n(\check{\xi}) = \check{\kappa}$, since $\sigma_n(\check{\kappa}) \subseteq \check{\kappa}$. But then, it follows that $\operatorname{ran}(\check{f}^G) \subseteq \check{\kappa} < \kappa$, because $\operatorname{ran}(\check{f}^G) = \sigma^*(\operatorname{ran}(\check{f}^D)) \subseteq \sigma^*(\check{\kappa}) \subseteq \check{\kappa} < \kappa$. This contradicts the fact that $a_0 \in G$ and $a_0$ forces that the range of $\check{f}$ is unbounded in $\kappa$.

**Case 2.2:** for all $i < \delta$, $\operatorname{cf}(\delta) > \delta(\mathbb{B}_i)$.

We may also assume that $\operatorname{cf}(\delta) > \omega_1$, for otherwise, $\operatorname{cf}(\delta) \leq \omega_1$ and the argument of case 2.1 goes through.

It follows as in [33] p. 143, claim (2)] that for $i < \delta$, $|i| \leq \delta(\mathbb{B}_i)$. But then, $\delta$ must be regular, for otherwise, if $i = \operatorname{cf}(\delta) < \delta$, it would follow that $\operatorname{cf}(\delta) = i \leq \delta(\mathbb{B}_i) < \operatorname{cf}(\delta)$.

3That fact should read: “Let $A \subseteq \mathbb{B}$, and let $\models_A \check{b} \in \mathbb{B} / G_A$, where $\check{b} \in V^A$. There is a unique $b \in \mathbb{B}$ such that $\models_A \check{b} = \check{b} / G_A$.” That’s what the proof given there shows.
Thus, $\delta$ is a regular cardinal, and $\delta \geq \omega_2$. Hence, $S^\delta_{1} \subseteq \delta$, the set of ordinals less than $\delta$ with cofinality $\omega_1$, is stationary in $\delta$. For $\gamma \in S^\delta_{1}$, since $\mathcal{B}_\gamma$, being subcomplete, preserves $\omega_1$, it follows that for every $i < \gamma$, $\Vdash_{\mathcal{B}_\gamma} \text{cf}(\check{\gamma}) > \omega$. Thus, $\mathcal{B}_\gamma$ is the direct limit of $\mathcal{B} \upharpoonright \gamma$. Moreover, since for $i < \delta$, $\delta(\mathcal{B}_i) < \delta = \text{cf}(\delta)$, it follows that $\mathcal{B}_i$ is $\delta(\mathcal{B}_i)^+\text{-c.c.}$, and hence $\delta\text{-c.c.}$.

It follows by Fact 4.16 that the direct limit of $\mathcal{B} \upharpoonright \delta$ is $\delta\text{-c.c.}$.

Again, since for all $i < \delta$, $\mathcal{B}_i$ is $\delta\text{-c.c.}$, $\mathcal{B}_\delta$ forces that the cofinality of $\delta$ is uncountable, so that $\mathcal{B}_\delta$ is the direct limit of $\mathcal{B} \upharpoonright \delta$, which is $\delta\text{-c.c.}$, as we have just seen. So $\mathcal{B}_\delta$ is $\delta\text{-c.c.}$.

Let $G$ be $\mathcal{B}_\delta$-generic over $V$, and suppose that in $V[G]$, $\kappa$ has countable cofinality. Since $\mathcal{B}_\delta$ is $\delta\text{-c.c.}$, it must be that $\kappa < \delta$. But letting $f : \omega \rightarrow \kappa$ be cofinal, $f \in V[G]$, it then follows that $f \in V[G \cap \mathcal{B}_\delta]$, for some $i < \delta$. This contradicts the minimality of $\delta$ and completes the proof. $\Box$

Looking back, it turns out that the theorem shows iterability with countable support.

**Corollary 4.18.** Let $\langle \mathcal{B}_i \mid i \leq \delta \rangle$ be a countable support iteration of complete Boolean algebras such that for all $i + 1 \leq \alpha$, the following hold:

1. $\mathcal{B}_i \neq \mathcal{B}_{i+1}$,
2. $\Vdash_{\mathcal{B}_i} (\mathcal{B}_{i+1} / G_{\mathcal{B}_i} \text{ is subcomplete and uncountable cofinality preserving}),$
3. $\Vdash_{\mathcal{B}_{i+1}} (\delta(\mathcal{B}_i) \text{ has cardinality at most } \omega_1)$.

Then for every $i \leq \delta$, $\mathcal{B}_i$ is subcomplete and uncountable cofinality preserving.

**Proof.** It is easy to see by induction on $i \leq \delta$ that $\mathcal{B}_i$ is subcomplete and uncountable cofinality preserving, and that if $i$ is a limit ordinal, then $\mathcal{B}_i$ is (isomorphic to) the rcs limit of $\mathcal{B} \upharpoonright i$. The successor case of the induction is trivial, so let $i \leq \delta$ be a limit ordinal. If we take $\mathcal{B}_i'$ to be the revised countable support limit of $\mathcal{B} \upharpoonright i$, then the resulting iteration $\mathcal{B} \upharpoonright i \mathcal{B}_i'$ is an rcs iteration, because inductively, $\mathcal{B} \upharpoonright i$ is. Hence, by the theorem, $\mathcal{B}_i'$ is subcomplete and uncountable cofinality preserving. But moreover, by the proof of the theorem, whenever $h \leq k < i$ and $G_h$ is $\mathcal{B}_h$-generic, it follows that $\mathcal{B}_k / G_h$ is uncountable cofinality preserving in $V[G_h]$. It follows that the rcs limit of $\mathcal{B} \upharpoonright i$ is the same as the countable support limit, and hence that $\mathcal{B}_i = \mathcal{B}_i'$ (modulo isomorphism). So $\mathcal{B}_i$ is subcomplete and uncountable cofinality preserving. $\Box$

The second set of ingredients I need is centered around bounded forcing axioms and their consistency strengths. These axioms were introduced in [25] as follows, albeit with a different notation.

**Definition 4.19.** Let $\Gamma$ be a class of forcings, and let $\kappa, \lambda$ be cardinals. Then $\text{BFA}(\Gamma, \leq \kappa, \leq \lambda)$ is the statement that if $P$ is a forcing in $\Gamma$, $\mathbb{B}$ is its complete Boolean algebra, and $\mathcal{A}$ is a collection of at most $\kappa$ many maximal antichains in $\mathbb{B}$, each of which has size at most $\lambda$, then there is a $\mathcal{A}$-generic filter in $\mathbb{B}$, that is, a filter that intersects each antichain in $\mathcal{A}$. When $\kappa = \omega_1$, then I usually don’t mention $\kappa$, that is, $\text{BFA}(\Gamma, \leq \lambda)$ is short for $\text{BFA}(\Gamma, \leq \omega_1, \leq \lambda)$. And when $\kappa = \lambda = \omega_1$, then the resulting principle is abbreviated to $\text{BFA}(\Gamma)$. If $\Gamma$ is the class of subcomplete forcings, then I write $\text{BSCFA}$ for $\text{BFA}(\text{SC})$ and $\text{BSCFA}(\leq \lambda)$ for $\text{BFA}(\text{SC}, \leq \lambda)$. Similarly, if $\Gamma$ is the class of proper forcing, then $\text{BPFA}$ denotes $\text{BFA}(\Gamma)$, and similarly for $\text{BPFA}(\leq \lambda)$. 

Bounded forcing axioms can be expressed as generic absoluteness principles as follows.

**Theorem 4.20** (Bagaria [2] Thm. 5). Let $\kappa$ be a cardinal of uncountable cofinality, and let $\mathbb{P}$ be a poset. Then $\text{BFA}([\mathbb{P}], \leq \kappa, \leq \kappa)$ is equivalent to $\Sigma_1(H_{\kappa^+})$-absoluteness for $\mathbb{P}$. The latter means that whenever $g$ is $\mathbb{P}$-generic, $\varphi(x)$ is a $\Sigma_1$-formula and $a \in H_{\kappa^+}$, then $V \models \varphi(a)$ iff $V[g] \models \varphi(a)$.

For any class $\Gamma$ of forcings, the principles $\text{BFA}(\leq \kappa)$ give closer and closer approximations to $\text{FA}(\Gamma)$, as $\kappa$ increases; in fact, $\text{FA}(\Gamma)$ is $\text{BFA}(\Gamma, \leq \kappa)$, or, for all $\kappa$, $\text{BFA}(\leq \kappa)$. The following characterization of these axioms is easily seen to be equivalent to the one given in [7, Thm. 1.3], see also [3].

**Fact 4.21.** $\text{BFA}([\mathbb{Q}], \leq \kappa)$ is equivalent to the following statement: if $M = \langle |M|, \in, \langle R_i \mid i < \omega_1 \rangle \rangle$ is a transitive model for the language of set theory with $\omega_1$ many predicate symbols $\langle R_i \mid i < \omega_1 \rangle$, of size $\kappa$, and $\varphi(x)$ is a $\Sigma_1$-formula, such that $M \models \varphi(M)$, then there are in $V$ a transitive $\mathbb{M} = \langle |\mathbb{M}|, \in, \langle R_i \mid i < \omega_1 \rangle \rangle$ and an elementary embedding $j : M \prec \mathbb{M}$ such that $\varphi(\mathbb{M})$ holds.

Miyamoto has analyzed the strength of these principles for proper forcing and introduced the following large cardinal concept, with slightly different terminology.

**Definition 4.22** ([36] Def. 1.1). Let $\kappa$ be a regular cardinal, $\alpha$ an ordinal, and $\lambda = \kappa^{+\alpha}$. Then $\kappa$ is $H_\lambda$-reflecting, or I will say $+\alpha$-reflecting, iff for every $a \in H_\lambda$ and any formula $\varphi(x)$, the following holds: if there is a cardinal $\theta$ such that $H_\theta \models \varphi(a)$, then the set of $N \prec H_\lambda$ such that

1. $N$ has size less than $\kappa$,
2. $a \in N$,
3. if $\pi_N : N \rightarrow H$ is the Mostowski-collapse of $N$, then there is a cardinal $\bar{\theta} < \kappa$ such that $H_{\bar{\theta}} \models \varphi(\pi_N(a))$

is stationary in $\mathcal{P}_\kappa(H_\lambda)$.

The concept of a reflecting cardinal was previously introduced in [25], and is contained in this definition, as it is not hard to see that being reflecting is equivalent to being $+0$-reflecting. The $+1$-reflecting cardinals are also known as strongly unfoldable cardinals, introduced independently in [39]. In the context of bounded forcing axioms, it seems to make the most sense to emphasize that they generalize reflecting cardinals, as it was shown in [25] that the consistency strength of BPFA is precisely a reflecting cardinal, and it was shown in [36] Def. 1.1] that the consistency strength of $\text{BPFA}(\leq \omega_2)$ is a $+1$-reflecting cardinal. I showed that the same consistency strength results hold for SCFA and SCFA$(\leq \omega_2)$ as well, in [17]. It will be important for the upcoming argument that $+1$-reflecting cardinals may exist in $L$; in fact, I showed in [17] that if $\text{SCFA}(\leq \omega_2)$ holds, then the cardinal $\omega_2^L$ is $+1$-reflecting in $L$.

Given this background, it is easy to observe that $\text{SC-SRP}(\omega_2) + \neg \text{CH}$ does not imply $\text{SCFA}(\leq \omega_2)$, since the consistency strength of $\text{SC-SRP}(\omega_2) + \neg \text{CH}$ is equal to that of $\text{ZFC}$ (in fact, $\neg \text{CH}$ implies $\text{SC-SRP}(\omega_2)$ by Observation [28,2]), while the consistency strength of $\text{BSCFA}(\leq \omega_2)$ is a $+1$-reflecting cardinal. I have now assembled the main tools needed to show that such a separation can also be arranged when $\text{CH}$ holds. This will be achieved by constructing a model of $\text{CH} + \text{SC-SRP}(\omega_2)$ in which the consequence of $\text{SCFA}(\leq \omega_2)$ stated in the following lemma fails (in an extreme way).
Lemma 4.23. Assume BSCFA(≤ω2). Then the set
\[ \{ \alpha < \omega_2 \mid \text{cf}(\alpha) = \omega \text{ and } \alpha \text{ is regular in } L \} \]
is stationary in ω2.

Proof. If 0# exists, then let I be the class of Silver indiscernibles, I \cap \omega_2 is club in \omega_2 and consists of L-regular cardinals. Therefore, I \cap S^\omega_2 is a stationary subset of the set in question.

So let me assume that 0# does not exist. The following argument traces back to Todorcević (unpublished), but see [11 Lemma 2.4]. A variant of the argument was used in [17 Lemma 4.11].

Let \( \kappa = \omega_2 \), and let \( \gamma \) be some singular strong limit cardinal, and let \( \theta = \gamma^+ = (\gamma^+)^L \), by Jensen’s covering lemma. Let \( E \subseteq \kappa \) be some club subset. Let \( X \subseteq H_{\omega_2} \) have cardinality \( \omega_2 \), \( \omega_2 \subseteq X \), and \( H_{\omega_2} \vdash X \prec H_{\omega_2} \). Let \( M = \langle X, \in, \emptyset, \ldots, \xi, \ldots, \omega_1 \rangle_{\xi<\omega_1} \). So the universe of \( M \) has size \( \omega_2 \).

Let \( \langle C_\xi \mid \xi \text{ is a singular ordinal in } L \rangle \) be the canonical global \( \Box \) sequence for \( L \) of Jensen [28]. It is \( \Sigma^1_1 \)-definable in \( L \) and has the properties that for every \( L \)-singular ordinal \( \xi \), the order type of \( C_\xi \) is less than \( \xi \), and if \( \zeta \) is a limit point of \( C_\xi \), then \( \zeta \) is singular in \( L \) and \( C_\zeta = C_\xi \cup \zeta \).

Let \( B = \{ \xi < \theta \mid \kappa < \xi < \theta \text{ and } \text{cf}(\xi) = \omega \} \). Note that by covering, every \( \xi \in B \) is singular in \( L \), since a countable cofinal subset of \( \xi \) in \( V \) can be covered by a set in \( L \) of cardinality at most \( \omega_1 \), so that its order type will be less than \( \kappa \), and hence less than \( \xi \). So \( C_\xi \) is defined for every \( \xi \in B \), and since the function \( \xi \mapsto \text{otp}(C_\xi) \) is regressive, there is a stationary subset \( A \) of \( B \) on which this function is constant.

Let \( g \subseteq \kappa \) be an \( \omega \)-sequence cofinal in \( \kappa \), added by Namba forcing, which is subcomplete. Since Namba forcing certainly has cardinality less than \( \theta \), \( A \) remains stationary in \( V[g] \). Working in \( V[g] \) now, since \( A \) consists of ordinals of cofinality \( \omega \) and is stationary in a regular cardinal greater than \( 2^\omega \), the forcing \( P_A \), which adds a subset \( F \) of \( A \) that’s closed and unbounded in \( \theta \) and has order type \( \omega_1 \), by forcing with closed initial segments, is subcomplete – this follows from Lemma 3.5 (see also [33] p. 134ff., Lemma 6.3), where the assumption that \( \theta > 2^\omega \) is omitted.

Let \( h \) be generic over \( V[g][F] \) for \( \text{Col}(\omega_1, M) \). Clearly, the composition of Namba forcing, \( P_A \) and \( \text{Col}(\omega_1, M) \) is subcomplete.

In \( V[g][F][h] \), the \( \Sigma^1_1 \)-statement \( \Phi(M) \) saying “there are an ordinal \( \theta' > \text{On} \cap M \), sets \( g' \) and \( F' \), and a function \( h' \) such that \( h' \) is a surjection from \( \omega_1^M \) onto the universe of \( M \), \( F' \) is a club in \( \theta' \) of order type \( \omega_1^M \) such that for all \( \xi, \zeta \in F' \), \( \text{otp}(C_\xi) = \text{otp}(C_\zeta) \), and \( g' \) is a cofinal subset of \( \text{On} \cap M \) of order type \( \omega_1 \), and in \( L_{\theta'} \), \( \text{On} \cap M \) is a regular cardinal greater than \( \omega_1^M \) holds, as witnessed by \( \theta, g, F \) and \( h \). It is important here that the definition of the canonical global \( \Box \) sequence is \( \Sigma^1_1 \). This does not depend on the particular choice of the generics \( g, F \) and \( h \), which means that it is forced by the trivial condition in the composition of these subcomplete forcings that \( \Phi(M) \) holds. So according to the characterization of BSCFA(≤ω2) given by Fact 4.22, there are a transitive \( \bar{M} = \langle \| \bar{M} \|, \in, E, \langle \xi \mid \xi < \omega_1 \rangle \rangle \) such that \( \Phi(M) \) holds, and an elementary embedding \( j : M \prec \bar{M} \). It follows that \( j \) is the identity. This is because we have constants for the countable ordinals, so that \( \omega_1^\bar{M} = \omega_1^M = \omega_1 \), and since \( M \) believes that the transitive closure of any set has cardinality at most \( \omega_1 \).

Let \( \bar{\kappa} = \text{On}^\bar{M} \), and let \( \bar{\theta}, \bar{g}, \bar{F}, \bar{h} \) witness that \( \Phi(\bar{M}) \) holds. Then \( \bar{h} : \omega_1 \to |\bar{M}| \) is onto, so \( \bar{\kappa} < \kappa \). Moreover, since \( \bar{M} \in H_{\omega_2} \), \( \bar{\theta} \) may be chosen to be less than \( \omega_2 \).
Uncountable cofinality in $L^\kappa$

Gunter Fuchs

...it follows that $\kappa \in E$. Moreover, $\kappa$ has countable cofinality, since $\bar{g}$ is a cofinal subset of $\kappa$ of order type $\omega$. I claim that $\kappa$ has uncountable cofinality in $L$, thus completing the proof.

The key point is that $\theta$ is a regular cardinal in $L$. To see this, assume that $\theta$ is singular in $L$. Then $[C_\theta]$ is defined. Note that $\text{cf}(\theta) = \omega_1$, since $\text{otp}(\bar{F}) = \omega_1$. So, letting $C^\nu_\theta$ be the set of limit points of $C_\theta$, $C^\nu_\theta \cap \bar{F}$ is club in $\theta$. Now take $\xi < \zeta$, both in $C^\nu_\theta \cap \bar{F}$. Then, since $\xi, \zeta \in \bar{F}$, $C_\xi$ and $C_\zeta$ have the same order type, but since both $\xi$ and $\zeta$ are limit points of $C^\nu_\theta$, $C_\xi = C^\nu_\theta \cap \xi$, which is a proper initial segment of $C_\xi = C^\nu_\theta \cap \xi$, a contradiction.

So, since by $\Phi(\bar{M})$, $\kappa$ is a regular cardinal in $L_\theta$, it follows that $\kappa$ is an uncountable regular cardinal in $L$, as wished. □

Lemma 4.24. Let $\Gamma$ be a forcing class.

1. $2^{\omega_1} = \omega_2 + \text{BFA}(\Gamma, \leq \omega_2)$ implies $\Gamma$-$\text{SRP}(\omega_2)$.

2. Let $\Gamma$ be the class of all subcomplete, uncountable cofinality preserving forcing notions. Then $\text{BFA}(\Gamma, \leq \omega_2)$ implies $\text{SC-SRP}(\omega_2)$.

Proof. To prove [1] first note that $H_{\omega_2}$ has cardinality $\omega_2$. To see that $\Delta$-$\text{SRP}(\omega_2)$ holds, let $S \subseteq [H_{\omega_2}]^{\omega_1}$ be $\Delta$-projective stationary. I will use the characterization of $\text{BFA}(\Delta, \leq \omega_2)$ given by Fact 4.21. Thus, let $M = \langle H_{\omega_2}, \in, S, 0, 1, \ldots, \Xi, \ldots \rangle_{\xi < \omega_1}$. Now the forcing $\mathbb{P}_S$ is in $\Gamma$, since $S$ is $\Delta$-projective stationary, and the size of the universe of $M$ is $\omega_2$, so that Fact 4.21 is applicable. Namely, the $\Sigma_1$-statement expressing that there is a continuous $\omega^M_2$-chain of models through $\bar{S}^M$ is forced by $\mathbb{P}_S$. So, by the fact, there are a transitive model $M$ of the same language as $M$, and an elementary embedding $j : \bar{M} \prec M$ such that the same $\Sigma_1$-statement is true of $M$. As in the proof of Lemma 4.23, $j$ is the identity.

To see [2] let $\Gamma$ be the class of all subcomplete, uncountable cofinality preserving forcing notions, and suppose that $\text{BFA}(\Gamma, \leq \omega_2)$ holds. If $\text{CH}$ fails, then $\text{SC-SRP}(\omega_2)$ holds trivially, by Observation 2.32. So let me assume $\text{CH}$. It then follow from $\text{BFA}(\Gamma, \leq \omega_2)$ that $\text{SFP}_{\omega_2}$ holds (see Definition 4.12). To see this, let $\bar{D} = \langle D_i \mid i < \omega_1 \rangle$ be a partition of $\omega_1$ into stationary sets, and let $\langle S_i \mid i < \omega_1 \rangle$ be a sequence of stationary subsets of $\omega^2_\omega$. By (the remark after) Lemma 3.18 the set

$$S = \{ a \in [H_{\omega_2}]^{\omega_1} \mid \forall i < \omega_1 a \cap \omega_1 \subseteq D_i \rightarrow \sup (a \cap \omega_2) \subseteq S_i \}$$

is fully spread out. This means that the forcing $\mathbb{P}_S$ is subcomplete, and by Fact 2.7 it is countably distributive and hence in $\Gamma$. Now let $N = \langle H_{\omega_1}, \in, \bar{D}, \bar{S}, 0, 1, \bar{\xi} \rangle$, viewed as a model of the language which has a predicate symbol for each $D_i$, $S_i$ and $\bar{\xi}$, for $i < \omega_1$. Let $\omega_2 \subseteq X$ be such that $M = N|X \prec N$ and such that $X$ has cardinality $\omega_2$. Let $\bar{M}$ be a continuous $\in$-chain through $S$, added by $\mathbb{P}_S$, and let’s assume that each $M_i$ is an elementary submodel of $\langle H_{\kappa}, \in, \bar{D}, \bar{S} \rangle$. Using the argument of Theorem 3.19 it follows that in $V[\bar{M}]$, there is a normal function $f : \omega_1 \rightarrow \omega^\kappa_\omega$, cofinal in $\text{On} \cap M$, such that for every $i < \omega_1$, $f^D_i \subseteq S_i$. This can be expressed as a $\Sigma_1$-statement about $M$. By $\text{BFA}(\Gamma, \leq \omega_2)$, there are in $\mathbb{V}$ a transitive model $M$ and an elementary embedding $j : \bar{M} \prec M$ such that this $\Sigma_1$-statement is true of $M$. Because of the availability of the constant symbols for the countable ordinals, it follows that $\omega_1 \subseteq \text{ran}(j)$, and hence $j|\omega_1 = \text{id}$. And since $\omega_1$ is the largest cardinal in $M$, the same is true in $\bar{M}$, and hence, letting $\bar{k} = \text{On} \cap \bar{M}$, it follows that $j|\bar{k}$ is the identity. In fact, since the transitive closure of every set...
Lemma 3.10] then shows that κ

Proof. The construction starts in a model of a single ordinal like that). So (5) holds in \(L\) forking \(P\) κ at composition \(P\). To define here what this principle says, since it will turn out to be equivalent to \(\text{BFA}\) to define here what this principle says, since it will turn out to be equivalent to \(\text{BFA}\).

By Observation 3.14 and Fact 3.15 \(SFP(\omega_2)\) implies that \(\omega_2^{\omega_1} = \omega_2\). Hence, by (1) we see that \(\Gamma\)-SRP(\(\omega_2\)) holds. But \(\Gamma\)-SRP(\(\omega_2\)) implies \(SC(\omega_2)\) (and by the way, the converse is also true, because \(\Gamma \subseteq SC\), because if \(S \subseteq [H_\kappa]^{\omega_2}\) is fully spread out, then \(\mathbb{P}_S\) is subcomplete, and \(\mathbb{P}_S\) is always countably distributive, hence uncountable cofinality preserving. Thus, \(\mathbb{P}_S\) is in \(\Gamma\), making \(S\) \(\Gamma\)-projective stationary. Therefore, by \(\Gamma\)-SRP(\(\omega_2\)), there is a continuous \(\in\)-chain through \(S\).

Now I'm ready to put the pieces together and construct the model in which \(SC(\omega_2)\) holds but \(\text{BSCFA}(\leq \omega_2)\) fails.

**Theorem 4.25.** Let \(\Gamma\) be the class of subcomplete, uncountable cofinality preserving forcing notions. If ZFC is consistent with \(\text{BFA}(\Gamma, \leq \omega_2)\), then ZFC is consistent with the conjunction of the following statements:

1. \(\text{CH}\),
2. \(\text{BFA}(\Gamma, \leq \omega_2)\),
3. \(\text{SC-SRP}(\omega_2)\),
4. \(L\) is correct about uncountable cofinalities, that is, for every ordinal \(\alpha\), if \(\text{cf}(\alpha) > \omega\), then \(\text{cf}(\alpha) > \omega\),
5. \(\neg \text{BSCFA}(\leq \omega_2)\).

**Proof.** The construction starts in a model of \(\text{BFA}(\Gamma, \leq \omega_2)\). The argument of [17] Lemma 3.10 then shows that \(\kappa = \omega_2\) is \(+1\)-reflecting in \(L\). Indeed, going through the proof shows that only forcing notions in \(\Gamma\) are used. So let us work in \(L\) of that model, where \(\kappa\) is \(+1\)-reflecting. By [17] Lemma 4.9, \(\kappa\) is remarkably \(\leq \kappa\)-reflecting in \(L\) (I do not want to go in the details here and explain what this means, but rather use the results of [17] as a black box as much as possible). Now the argument of [17] Lemma 4.13 shows that in \(L\), there is a \(\kappa\)-c.c. forcing notion \(P\) such that if \(G\) is generic for \(P\), then in \(L[G]\), a principle called \(\text{wBFA}(\Gamma, \leq \kappa)\) holds (I don’t want to define here what this principle says, since it will turn out to be equivalent to \(\text{BFA}(\Gamma, \leq \kappa)\) in the present situation). \(L[G]\) is the desired model. I will show that it satisfies (1)–(5).

The forcing \(\mathbb{P}\) is of the form \(\mathbb{P}_0 \ast \mathbb{P}_1\), where \(\mathbb{P}_0\) is Woodin’s fast function forcing at \(\kappa\) and \(\mathbb{P}_1\) is a \(\mathbb{P}_0\)-name for an iteration of forcings in \(\Gamma\) as in Theorem 4.17. The forcing \(\mathbb{P}_0\) is \(\kappa\)-c.c. and (much more than) countably closed. It follows that the composition \(\mathbb{P} = \mathbb{P}_0 \ast \mathbb{P}_1\) is in \(\Gamma\), and hence, it follows that in \(L[G]\), \(L\) is correct about uncountable cofinalities, that is, (4) holds in \(L[G]\). This implies, by Lemma 4.25 that \(\text{BSCFA}(\leq \omega_2)\) fails, since otherwise, stationarily many ordinals below \(\omega_2\) would have to be regular in \(L\) yet of countable cofinality in \(L[G]\) (but there is not a single ordinal like that). So (5) holds in \(L[G]\).

Let \(G = G_0 \ast G_1\), where \(G_0\) is \(\mathbb{P}_0\)-generic over \(L\) and \(G_1\) is \(\mathbb{P}_1^{G_0}\)-generic over \(L[G_0]\). By [17] Lemma 4.13, \(\kappa\) is still \(+1\)-reflecting in \(L[G_0]\), and in particular inaccessible.

Working in \(L[G_0]\), temporarily, let me analyze the iteration giving rise to \(\mathbb{P}_1\). It is an iteration of length \(\kappa\) such that each initial segment of the iteration is in \(V_\kappa\) (in the sense of \(L[G_0]\)). Due to the intermediate collapses in the iteration, it follows that \(\kappa = \omega_2^{L[G]}\). Thus, in \(L[G]\), we have \(\text{wBFA}(\Gamma, \leq \omega_2)\), which, by [17] Obs. 4.7,
is equivalent to BFA(Γ, ≤ω2). Thus, we have (2) By part (2) of Lemma 1.24, this implies SC-SRP(ω2), so that (3) is satisfied. The collapses in the iteration will force CH, and once CH is true, it remains true, since no reals are added, so we have (1) completing the proof. □

In the follow-up article [8], joint with Sean Cox, we will introduce a diagonal version of SRP, which strengthens SRP, and we will consider the canonical fragments of this principle. The principle is designed in such a way that it captures those MM-consequences on diagonal reflection that SRP fails to capture. Thus, the subcomplete fragment of the diagonal SRP implies that for regular κ > 2ω, DSR(ω1, Sκω) holds, and the full principle (that is, the stationary set preserving fragment) implies this for regular κ > ω1. Thus, neither Larson’s result separating SRP from MM, nor Theorem 4.7 serve to separate the subcomplete fragment of the diagonal SRP from SCFA. However, the previous result, Theorem 4.25, does provide such a separation at the level ω2 because, using the terminology used in its statement, in the model constructed, we have BFA(Γ, ≤ω2) + CH + 2ω1 = ω2, and this implies the subcomplete fragment of the diagonal SRP. Since BSCFA(≤ω2) fails in the model, this shows that the subcomplete fragment of the diagonal SRP at ω2 does not imply BSCFA(≤ω2).

5. Questions

I will list questions by the related section in this article.

Section 2. in subsection 2.2, the present formulation of the Γ-fragment of SRP is given, postulating that if the natural forcing P S to add a continuous ∈-chain through a stationary set S is in Γ, then such a sequence exists. A potentially stronger formulation would ask that if there is any forcing in Γ that adds such a sequence, then such a sequence should exist. The question is whether this can be a stronger principle. More broadly, can there be forcings in Γ that add such a sequence when P S is not in Γ? Subsection 2.3 introduced the subcomplete fragment of SRP, and an early observation was that SC-SRP(κ) holds trivially if κ ≤ 2ω. It is then natural to ask whether SC-SRP is consistent with 2ω > ω2. The same can be asked about SCFA instead of SC-SRP.

Section 3. there is a lot of room for questions here. Many consequences of SRP obviously don’t follow from its subcomplete fragment, but many others might. For example, the weak reflection principle WRP, or the strong Chang conjecture, would be candidates. One may ask the same questions about the full forcing axiom SCFA. In fact, these principles follow from SCFA+, so assuming the consistency of a supercompact cardinal, they are consistent with SCFA+, together with ♦, say. It would also be interesting to explore consequences of Theorem 3.33 on the mutual stationarity of sequences of sets of exact simultaneous reflection points. Another question is whether MM implies the full principle SFPω2 in which it is not assumed that the sequence D is a maximal partition of ω1 into stationary sets (see Definition 3.12). If not, then this would be a consequence of the subcomplete fragment of SRP with CH that does not follow from MM.

Section 4. the first main question for this section concerns subsections 4.1 and 4.2 and asks whether the combination of CH with the subcomplete fragment of SRP implies OSRω2, or uDSR(λ, Sκω), for any regular κ ≥ ω2 and any λ with 1 ≤ λ ≤ ω1. A negative answer would separate SC-SRP + CH from SCFA, in fact, it would even separate SC-SRP + CH from the subcomplete fragment of the diagonal
strong reflection principle mentioned at the end of Section 4.3, to be introduced in [8]. The underlying question here is how to guarantee the preservation of spread out sets. Regarding subsection 4.3, there is a fundamental problem concerning the difference between $\infty$-subcompleteness and subcompleteness: can a forcing be found that is $\infty$-subcomplete but not subcomplete? Does the Iteration Theorem 4.17 go through for $\infty$-subcomplete forcing? Can the separation result be modified to show that $\infty$-SC-$\text{SRP}(\omega_2) + \text{CH}$ does not imply $\infty$-SCFA($\omega_2$)? Finally, is there a global version of the result, separating SCFA from the combination of the subcomplete fragment of SRP with CH? This would most likely also separate the combination of the subcomplete fragment of the diagonal strong reflection principle with CH from SCFA.

Questions abound.
