**Abstract**

A 56-year-old woman, without any immunocompromising diseases, was referred to our hospital because of a recurrence of pyogenic spondylitis. Computed tomography revealed multiple osteolytic changes in the whole body. Vertebral magnetic resonance imaging revealed osteomyelitis and spondylitis. *Mycobacterium scrofulaceum* was detected in sputum cultures, in abscesses from the right knee, and in a subcutaneous forehead abscess. Therefore, the patient was diagnosed with disseminated *Mycobacterium scrofulaceum* infection. The patient was treated with rifampicin, ethambutol, and clarithromycin, which resulted in symptomatic relief and radiological improvement. We herein report a rare case of disseminated *Mycobacterium scrofulaceum* infection in an immunocompetent host.

**Key words:** *Mycobacterium scrofulaceum*, osteomyelitis, pyogenic spondylitis

(Intern Med 56: 1931-1935, 2017)  
(DOI: 10.2169/internalmedicine.56.8181)

**Introduction**

*Nontuberculous mycobacteria* (NTM) are widely found in the environment, such as in dust, soil, and water and more than 150 species have been identified. *Mycobacterium scrofulaceum* is a slow-growing NTM and classified in the Runyon group II. *M. scrofulaceum* infections are rare and account for around 2.2% of NTM infections (1). There are only a few reports describing disseminated mycobacterial infections due to *M. scrofulaceum* (2-10). We herein report a rare case of disseminated *M. scrofulaceum* infection in an immunocompetent host.

**Case Report**

A 56-year-old woman suffering from fever and general fatigue visited a neighboring hospital and was examined. During her hospitalization, pyogenic spondylitis complicated by an iliopsoas abscess, due to an infection with *Mycobacterium* species, was diagnosed. However, the species causing the condition was not identified. An infection with *Mycobacterium tuberculosis* was suspected, and isoniazid (INH), rifampicin (RFP), pyrazinamide, and ethambutol (EB) were prescribed for 2 months from January 2011. Following the initial treatment, INH and RFP were prescribed for 7 additional months. However, the patient’s fever persisted, and the iliopsoas abscess gradually worsened. Therefore, in June 2011, for a period of 2 months, a daily dose of 500 mg levofloxacin (LVFX) was added to the INH and RFP regi-

Correspondence to Dr. Hirokazu Tokuyasu, tokuun3200@yahoo.co.jp
men, and the abscess improved. In April 2014, the patient was referred to our hospital for further examination and treatment because of a recurrence of pyogenic spondylitis.

The results of the physical examination were as follows: body temperature, 36.8°C; pulse rate, 68 beats per minute; blood pressure, 93/75 mmHg; respiratory rate, 16 breaths per minute; and oxygen saturation, 97% on room air. Respiratory sounds and cardiac and abdominal examination findings were normal. There was a purulent region on the left sinciput (Fig. 1) and her right knee was slightly red, swollen, and painful.

The white blood cell count was 12,100/μL with 73.4% neutrophils, 14.2% lymphocytes, 4.2% monocytes, 7.7% eosinophils, and 0.5% basophils. The levels of C-reactive protein, alkaline phosphatase, and soluble interleukin-2 receptor were elevated to 18.25 mg/dL (normal range: 0-0.3 mg/dL), 988 U/L (normal range: 110-340 U/L), and 4,459 U/mL (normal range: 127-582 U/mL), respectively. Tests for serum antibodies to T-cell leukemia virus and immunodeficiency virus yielded negative results. An interferon-gamma (IFN-γ) release assay, QuantiFERON®-TB Gold (QFT-G) was indeterminate (M. tuberculosis antigen response: <0.05 IU/mL; negative control: <0.05 IU/mL; mitogen response: <0.05 IU/mL).

Computed tomography (CT) revealed osteolytic changes in the vertebrae and abscesses adjacent to the T3 vertebral body (Fig. 2A). 18-fluorine-fluorodeoxyglucose positron emission tomography/CT (FDG-PET/CT) examination showed multiple lesions with an intense FDG accumulation in the abscesses adjacent to the T3 vertebral body and various bones, such as the skull, sternum, clavicles, ribs, vertebral columns, scapulae, pelvic bones, bilateral humerus, and thigh bones. These findings of osteolytic changes in the bones of the whole body more strongly suggested the presence of metastatic carcinomas and blood diseases, such as malignant lymphoma and multiple myeloma than the existence of bacterial infections.

T2-weighted imaging (WI) and diffusion-WI (DWI) revealed several hyperintense signals in the vertebral bodies, their surroundings, and intervertebral spaces.

M. scrofulaceum was detected in a sputum culture, the abscesses of the right knee, and the subcutaneous forehead abscess. In vitro, the bacterial isolate was resistant to INH, EB, and para-aminosalicylic acid (PAS), but it was sensitive to streptomycin (SM), RFP, cycloserine (CS), kanamycin (KM), enviomycin (EVM), ethionamide (ETH), and LVFX (Vite Spectrum SR, Kyokuto Pharmaceutical Industrial, Tokyo, Japan). The minimum inhibitory concentrations (MICs) reported for RFP, EB, and SM were 40 μg/mL, 2.5 μg/mL, and 10 μg/mL, respectively (Broth MIC NTM, Kyokuto Pharmaceutical Industrial, Tokyo, Japan). The patient was prescribed a combination antibiotic therapy with RFP, 300 mg daily; EB, 500 mg daily; clarithromycin (CAM), 800 mg daily; and SM, 500 mg 3 times a week, from July to August 2014. After completing the first treatment regime, she was prescribed additional treatment with 3 drugs (RFP, EB, and CAM) from September 2014 to August 2016, which resulted in symptomatic relief and a radiological improvement (Fig. 2B).
tions due to this organism are relatively rare. Lung lymphadenitis in pre-school children (12). Pulmonary infec-
tion therapy (RFP, CAM, and EB) over a 2-year period. An immunocompetent host was successfully treated with combi-
microbial infection, caused by M. scrofulaceum, in an

immunocompetent host was successfully treated with combi-
mication therapy (RFP, CAM, and EB) over a 2-year period.

Discussion

The name M. scrofulaceum derives from “scrofula”, an in-
fected in the cervical lymph nodes, and it is relatively well 
known that M. scrofulaceum is associated with cervicofacial 
lymphadenitis in pre-school children (12). Pulmonary infec-
tions due to this organism are relatively rare. Lung M. scrof-
ulaceum infections account for around 0.7% of nontubercu-
ious lung mycobacteriosis in Japan (13). The characteristic 
of pulmonary lesions is slowly-progressive cavernous pneu-
monia (1). Disseminated M. scrofulaceum infections are 
variably reported (2-10). In the present case, a disseminated 
ycobacterial infection, caused by M. scrofulaceum, in an 
immunocompetent host was successfully treated with combi-
nation therapy (RFP, CAM, and EB) over a 2-year period.

To our knowledge, only 10 cases, including this case, with 
detailed descriptions of disseminated M. scrofulaceum in-
fec tion in multiple organs, or even a single internal organ, 
have been published in the English literature since 1971 (Ta-
ble) (2-10). Four cases involved children, whereas 6 cases 
olved adults, comprising 8 men and 3 women. The mean 
age of these 10 patients was 25 years (age range: 2-56 
ears). For the pediatric cases, the identified underlying 
cause of the disease were advanced systemic amyloidosis 
and IFN-\(\gamma\) receptor 1 (IFN-\(\gamma R1\)) deficiency (2-4). In the case 
of amyloidosis, the relationship between secondary amyloi-
dosis and immunity was uncertain, and Dustin et al. con-
cluded that the prolonged stimulation of the immune system 
by the weakly antigenic M. scrofulaceum appeared to be the 
main cause of amyloidosis (2). Regarding the adult cases, 1 
patient had an underlying immunodeficiency due to

### Table. Features of Disseminated Mycobacterium Scrofulaceum Infection.

| No | Reference | Age/Sex | Lesion | Treatment | Outcome | Underlying disease |
|----|-----------|---------|--------|-----------|---------|--------------------|
| 1  | [7]       | 37/F    | Liver  | INH, SM, EB | Death   | Leukemia           |
| 2  | [10]      | 6/M     | Skin, Bone marrow | INH, SM, Operation | Recurrence | NR                  |
| 3  | [2]       | 9/M     | Skin, Lymph node, Lung, Liver, Testis, Epididymis, Kidney | INH, RFP, SM, PAS, CS, ETH, CLF, DDS, TAC | Death | Amyloidosis         |
| 4  | [9]       | 39/M    | Liver  | INH, RFP, CS | Cure | NR                  |
| 5  | [6]       | 38/F    | Lung, Skin | INH, RFP, EB, ETH, CS, MINO, Operation | Recurrence | Leukemia           |
| 6  | [5]       | 32/M    | Lung, Skin | INH, SM, RFP, EB, PZA | Death | AIDS               |
| 7  | [8]       | 27/M    | Lung, Lymph node, Liver, Bone marrow, Skin, Kidney | INH, EB, RFP, OFLX | Cure | Nothing            |
| 8  | [3]       | 2/M     | Bone marrow, Lymph node | RFP, RBT, CAM | Recurrence | IFN-\(\gamma\) deficiency |
| 9  | [4]       | 2/M     | Bone marrow | RFP, RBT, CAM | Recurrence | IFN-\(\gamma\) deficiency |
| 10 | This case | 56/F   | Bone marrow, Skin, Lung | RFP, EB, CAM, SM | Cure | Nothing            |

CAM: clarithromycin, CLF: clofazimine, CS: cycloserine, DDS: dapsone, EB: ethambutol, ETH: ethionamide, IFN-\(\gamma\): interferon-gamma, INH: isoniazid, MINO: minocycline, NR: not reported, OFLX: ofloxacin, PAS: para-aminosalicylic acid, PZA: pyrazinamide, RBT: rifabutin, RFP: rifampicin, SM: streptomycin, TAC: thiacetazone

**Figure 4.** A T2-weighted image (A: coronal image, B: axial image) and diffusion-weighted image (C) of the right knee showing hyperintense signals in the thigh bone and tibia. Abscesses in the lateral condyle of the tibia can be seen extending to the outside of the bone and up to proximal fibula. In addition, the abscesses extended to the joint cavity.

To our knowledge, only 10 cases, including this case, with detailed descriptions of disseminated M. scrofulaceum infection in multiple organs, or even a single internal organ, have been published in the English literature since 1971 (Table) (2-10). Four cases involved children, whereas 6 cases involved adults, comprising 8 men and 3 women. The mean age of these 10 patients was 25 years (age range: 2-56 years). For the pediatric cases, the identified underlying cause of the disease were advanced systemic amyloidosis and IFN-\(\gamma\) receptor 1 (IFN-\(\gamma R1\)) deficiency (2-4). In the case of amyloidosis, the relationship between secondary amyloidosis and immunity was uncertain, and Dustin et al. concluded that the prolonged stimulation of the immune system by the weakly antigenic M. scrofulaceum appeared to be the main cause of amyloidosis (2). Regarding the adult cases, 1 patient had an underlying immunodeficiency due to
AIDS (5). The patient diagnosed with AIDS had a CD4 lymphocyte count of 13/mm³ and presented with chronic ulcerative and nodular skin lesions with probable cavitary lung involvement (5). Two patients had leukemia-related underlying diseases (6, 7). There was no known immunodeficiency in the two cases, including the present case (8). The patient presented herein had slight lymphopenia and a low mitogen response in the QFT-G assay. A low mitogen response may occur because of an insufficient number of lymphocytes or the presence of IFN-γ antibodies (14). In our case, lymphopenia or the hypofunction of the lymphocytes might be related to disseminated M. scrofulaceum infection.

The areas of the body with lesions, due to disseminated M. scrofulaceum infection, included the skin (6 cases), bone marrow (5 cases), lung (5 cases), and liver (4 cases). In the four cases with liver involvement alone and IFN-γR1 deficiency, the course of invasion was unclear (3, 4, 7, 9). The 5 patients with associated lung lesions were thought to have been infected via the lung (2, 5, 6, 8). Lincoln and Gilbert reported that the onset of osteomyelitis due to M. scrofulaceum began with small, swollen, reddened areas of the skin overlying affected bones (10). These findings suggest that these bacteria can invade the skin and spread from there to other organs.

In this case, the MICs for M. scrofulaceum were determined using the Middlebrook 7H9 broth microdilution system based on clinical and laboratory standards institute 2003. In this method, the in vitro susceptibilities for many NTM do not correlate well with clinical response to anti-tuberculous drugs, except for CAM. Therefore it is considered that in vitro susceptibility data of NTM isolates other than CAM should be used as a reference (15). A few reports have described the sensitivity of M. scrofulaceum towards anti-tuberculous drugs. M. scrofulaceum is one of the NTMs which tends to demonstrate antibiotic resistance. Some strains of M. scrofulaceum were reported to be resistant to INH, PAS, and KM whereas other strains were sensitive to RFP, rifabutin, EB, SM, CS, amikacin, and ETH (1). Some studies showed that the MIC for 90% of the strains (MIC₉₀) for CAM was ≤0.5 μg/mL (16), for roxithromycin was ≤1.0 μg/mL (17), and for sparfloxacin was 1.0 μg/mL (18). Thus, these drugs may be useful for the treatment of M. scrofulaceum infections.

Furthermore, the required treatment periods for disseminated M. scrofulaceum infection are unknown. It is believed that the treatment period may change depending on the patient’s state of immunity. There are currently 2 cases that have been reported to be cured by drugs. Patel et al. described that treatment with INH, RFP, and CS against hepatic granulomatosis for 1 year improved the symptoms and normalized laboratory results (9). In this case an underlying disease was not reported. Hsueh et al. reported that the patient with no underlying disease was given a combination therapy of INH, RFP, EB, and Ofloxac in for 1 year and was cured (8). No long-term follow up with the patients was carried out in either of the reports. In our case, a treatment for 2 months, with 2 antibiotics (RFP, LVFX) to which the organism was found to be sensitive in vitro, caused the disease to recur. A combination therapy with RFP, CAM, and EB over a 2-year period was successful in curing the patient. A treatment regime with more than 2 antibiotics to which the organism is sensitive to over a period of more than 1 year might thus be necessary to cure the disease. In addition, it is necessary to monitor the patient for any recurrent infection. Further investigations into the most appropriate combination therapy for infections with M. scrofulaceum are therefore necessary.

The authors state that they have no Conflict of Interest (COI).
