1. Introduction

A celebrated theorem of Selberg [32] states that for congruence subgroups of \( \text{SL}_2(\mathbb{Z}) \) there are no exceptional eigenvalues below 3/16. We prove a generalization of Selberg’s theorem for infinite index “congruence” subgroups of \( \text{SL}_2(\mathbb{Z}) \). Consequently we obtain sharp upper bounds in the affine linear sieve, where in contrast to [4] we use an archimedean norm to order the elements.

Let \( \Lambda \) be a finitely generated non-elementary subgroup of \( \text{SL}_2(\mathbb{Z}) \); let \( X_\Lambda = \Lambda \backslash \mathbb{H} \) be the corresponding hyperbolic surface (which is of infinite volume if \( \Lambda \) is of infinite index in \( \text{SL}(2, \mathbb{Z}) \)). Let \( \delta(\Lambda) \) denote the Hausdorff dimension of the limit set of \( \Lambda \). The generalization of Selberg’s theorem splits into two cases: \( \delta(\Lambda) > \frac{1}{2} \) and \( 0 < \delta(\Lambda) \leq \frac{1}{2} \).

In the case that \( \delta(\Lambda) > \frac{1}{2} \) the spectrum of the Laplace-Beltrami operator on \( L^2(X_\Lambda) \) consists of finite number of points in \([0, \frac{1}{4}]\) (see [17]). We denote them by

\[
0 \leq \lambda_0(\Lambda) < \lambda_1(\Lambda) \leq \cdots \leq \lambda_{\text{max}}(\Lambda) < \frac{1}{4}.
\]

The assumption that \( \delta(\Lambda) > \frac{1}{2} \) is equivalent to \( \lambda_0(\Lambda) < \frac{1}{4} \), and in this case \( \delta(1 - \delta) = \lambda_0(\Lambda) \) [24].

The following extension of Selberg’s theorem is proved in section 2.

**Theorem 1.1.** Let \( \Lambda \) be a finitely generated subgroup of \( \text{SL}(2, \mathbb{Z}) \) with \( \delta(\Lambda) > \frac{1}{2} \). For \( q \geq 1 \) let \( \Lambda(q) \) be the “congruence” subgroup \( \{ x \in \Lambda : x \equiv I \mod q \} \). There is \( \varepsilon = \varepsilon(\Lambda) > 0 \) such that

\[
\lambda_1(\Lambda(q)) \geq \lambda_0(\Lambda(q)) + \varepsilon,
\]

for all square-free \( q \geq 1 \) (note that \( \lambda_0(\Lambda(q)) = \lambda_0(\Lambda) \)).

The first author was supported in part by the NSF. The second author was supported in part by DARPA, NSF, and the Sloan Foundation. The third author was supported in part by the NSF.
In [11] an explicit and stronger version of Theorem 1.1 is proven under the assumption that \( \delta(\Lambda) > \frac{5}{6} \). See [29] for the sharpest known bounds towards Selberg’s \( \frac{1}{4} \) Conjecture as well as bounds towards the Ramanujan Conjectures for more general groups.

Theorem 1.1 is a consequence of Theorem 1.2 in [4] and the following result, which is of independent interest.

**Theorem 1.2.** Let \( \Lambda = \langle S \rangle \) be a finitely generated subgroup of \( \text{SL}(2, \mathbb{R}) \) with \( \delta(\Lambda) > \frac{1}{2} \). Let \( \{N_i\} \) be a family of finite index normal subgroups of \( \Lambda \). Then the following are equivalent

1. The Cayley graphs \( G(\Lambda/N_i, S) \) form a family of expanders.
2. There is \( \varepsilon = \varepsilon(\Lambda) > 0 \) such that \( \lambda_1(\Lambda/N_i) \geq \lambda_0(\Lambda/N_i) + \varepsilon \).

The argument in section 2 establishes that 1 \( \Rightarrow \) 2; the implication 2 \( \Rightarrow \) 1 is proved using Fell’s continuity of induction in section 7 of [11].

Theorem 1.2 generalizes results of Brooks [5] and Burger [6, 7] who proved it in the case of co-compact \( \Lambda \).

Combining Theorem 1.1 with Lax-Phillips theory of asymptotic distribution of lattice points [17] we obtain the following result, which is the crucial ingredient in the execution of the affine linear sieve in the archimedean norm.

**Theorem 1.3.** Let \( \Lambda \) be a finitely generated subgroup of \( \text{SL}(2, \mathbb{Z}) \) with \( \delta(\Lambda) > \frac{1}{2} \). Assume that \( q \) is square free and \( (q, q_0) = 1 \), where \( q_0 \) is provided by the strong approximation theorem [19]. There is \( \varepsilon_1 > 0 \) depending on \( \Lambda \) such that for any \( g \in \text{SL}_2(q) \) we have

\[
|\{ \gamma \in \Lambda \mid \|\gamma\| \leq T \text{ and } \gamma \equiv g \mod q \}| = c\Lambda T^{2\delta} \frac{|\text{SL}_2(q)|}{|\Lambda|} + O(q^3T^{2\delta-\varepsilon_1}).
\]

(1.1)

We now turn to the discussion of the case \( \delta(X) \leq \frac{1}{2} \). In this case there is no discrete \( L^2 \) spectrum and its natural replacement is furnished by the resonances of \( X \), which are given as the poles of the meromorphic continuation of the resolvent \( R_X(s) = \Delta_X - s(1 - s)^{-1} \). By the result of Patterson [24] and Sullivan [34] \( R_X(s) \) is analytic for \( \Re(s) > \delta \); Mazzeo and Melrose [20] proved that \( R_X(s) \) has a meromorphic continuation to the entire plane. In [25] Patterson proved that \( R_X(s) \) has a simple pole at \( s = \delta \) and no further poles on the line \( \Re(s) = \delta \); his proof is based on ideas from ergodic theory related to Ruelle zeta-function. Using further development of these ideas due to Dolgopyat [8], Naud [21] has recently established that \( R_X(s) \) is holomorphic (with the exception of simple pole at \( s = \delta \)) for \( \Re(s) > \delta - \varepsilon \),
with \( \varepsilon \) depending on \( X \). The following result, giving a resonance-free region for congruence resolvent, is proved in section \( \{1\} \).

**Theorem 1.4.** Let \( \Lambda \) be a finitely generated subgroup of \( \text{SL}(2, \mathbb{Z}) \) with \( \delta(\Lambda) \leq \frac{1}{2} \). For \( q \geq 1 \) square free let \( \Lambda(q) \) be the “congruence” subgroup \( \{ x \in \Lambda : x \equiv I \mod q \} \); let \( X(q) = \Lambda(q) \backslash \mathbb{H} \). There is \( \varepsilon = \varepsilon(\Lambda) > 0 \) such that \( R_{X(q)}(s) \) is holomorphic (with the exception of simple pole at \( s = \delta \)) for \( \Re(s) > \delta - \varepsilon \min \left( 1, \frac{1}{\log(1+|3s|)} \right) \).

When \( \delta \leq \frac{1}{2} \) we cannot apply the expansion property \( \{4\} \) directly; instead, to prove theorem \( \{1.4\} \) we use a dynamical treatment and invoke a generalization of the underlying result on measure convolution (“\( L^2 \)-flattening lemma”): see Lemmas \( \{1\} \) and \( \{2\} \) in section \( \{7\} \). It is likely that by combining our methods with the extension of Dolgopyat’s result \( \{8\} \) to vector-valued functions, analyticity of \( R_{X(q)}(s) \) can be established for \( \Re(s) > \delta - \varepsilon \) — in complete analogy \( \{4\} \) in with Theorem \( \{1.1\} \).

Using methods of Lalley \( \{16\} \), we obtain the following analogue of Theorem \( \{1.3\} \) which is sufficient for sieving applications.

**Theorem 1.5.** Let \( \Lambda \) be a finitely generated subgroup of \( \text{SL}(2, \mathbb{Z}) \) with \( 0 < \delta(\Lambda) \leq \frac{1}{2} \). Assume that \( q \) is square free and \( (q, q_0) = 1 \), where \( q_0 \) is provided by the strong approximation theorem \( \{19\} \). There is \( \varepsilon_1 > 0 \), \( C > 0 \) depending on \( \Lambda \) such that for any \( g \in \text{SL}_2(q) \) we have

\[
\left| \{ \gamma \in \Lambda \mid \|\gamma\| \leq T \text{ and } \gamma \equiv g \mod q \} \right| = \frac{c_A T^{2\delta}}{|\text{SL}_2(q)|} \left( 1 + O \left( T^{-\frac{1}{\log \log T}} \right) \right) + O \left( q^C T^{2\delta - \varepsilon_1} \right).
\]

We turn to applications to affine linear sieve \( \{4\} \). Consider the standard action on the two by two integer matrices by multiplication on the left, and take the orbit \( \mathcal{O} \) of \( I \) (the identity matrix) under \( \Lambda \). Set \( |x| = \left( \sum_{i,j} x_{ij}^2 \right)^{\frac{1}{2}} \) where \( x = \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix} \). Set \( N_\Lambda(T) = \{|x \in \Lambda : |x| \leq T|\} \) and let \( \delta(\Lambda) \) be the Hausdorff dimension of the limit set of an orbit.

---

1 The analogy between Theorem \( \{1.1\} \) and Theorem \( \{1.4\} \) becomes clearer when their assertions are expressed in terms of the Selberg zeta function \( \{31\} \). If \( \Lambda \) is a finitely generated subgroups of \( \text{SL}_2(\mathbb{R}) \) the Selberg zeta function \( Z_X(s) \) associated with \( X = \Lambda \backslash \mathbb{H} \) is known to be an entire function, whose non-trivial zeros are given by the resonances and the finite point spectrum \( \{12\} \{26\} \). Consequently, Theorem \( \{1.1\} \) is equivalent to the assertion that when \( \delta(\Lambda) > \frac{1}{2} \) there is \( \varepsilon(\Lambda) > 0 \) such that \( Z_{X(q)}(s) \) is analytic and non-vanishing on the set \( \{ \Re(s) > \delta - \varepsilon \} \), except at \( s = \delta \) which is a simple zero, while Theorem \( \{1.4\} \) is equivalent to the assertion that when \( \delta(\Lambda) \leq \frac{1}{2} \) there is \( \varepsilon(\Lambda) > 0 \) such that \( Z_{X(q)}(s) \) is analytic and non-vanishing on the set \( \{ \Re(s) > \delta - \varepsilon \min \left( 1, \frac{1}{\log(1+|3s|)} \right) \} \), except at \( s = \delta \) which is a simple zero.
\[ \Lambda z \subset \mathbb{H} \cup \{\infty\} \cup \mathbb{R} , \text{ where } \mathbb{H} \text{ is the hyperbolic plane, } z \in \mathbb{H} \text{ and } \Lambda \text{ act by linear fractional transformations.} \]

By the results of Lax-Phillips [17] and Lalley [16] we have that \( N_{\Lambda}(T) \sim c_{\Lambda} T^{2\delta(\Lambda)}, \) as \( T \to \infty. \) Let \( f \in \mathbb{Q}[x_{ij}] \) be integral on \( O \) and assume that it is weakly primitive for \( O, \) that is \( \gcd \{ f(x) : x \in O \} = 1. \) If \( f \) is not weakly primitive then \( 1/N f \) is, where \( N = \gcd f(O), \) and we can represent any weakly primitive \( f \) as \( 1/N g \) with \( g \in \mathbb{Z}[x_{ij}] \) and \( N = \gcd(O). \)

The coordinate ring \( \mathbb{Q}[x_{ij}]/(\det(x_{ij}) - 1) \) is a unique factorization domain [28] and we can factor \( f \) into \( t = t(f) \) irreducibles \( f_1 f_2 \ldots f_t \) in this ring. Set

\[ \pi_{\Lambda, f}(T) = |\{x \in \Lambda; |x| \leq T, f_j(x) \text{ is prime for } j = 1,\ldots,t\}|. \]

For \( f \in \mathbb{Z}[x_{ij}] \) weakly primitive with \( t(f) \) irreducible factors our conjectured asymptotics is of the form:

\[ (1.3) \quad \pi_{\Lambda, f}(T) \sim \frac{c(\Lambda, f) N_{\Lambda}(T)}{(\log T)^{t(f)}}, \quad \text{as } T \to \infty, \]

where \( c(\Lambda, f) \) can be expressed as a product of local densities; see [10, 30] for an example of explicit computation and numerical experiments. In section 13 we establish the following sharp upper bound for \( \pi_{\Lambda, f}(T). \)

**Theorem 1.6.** Let \( \Lambda \) be a subgroup of \( \text{SL}(2, \mathbb{Z}) \) which is Zariski dense in \( \text{SL}_2 \) and let \( f \in \mathbb{Z}[x_{ij}] \) be weakly primitive with \( t(f) \) irreducible factors. Then

\[ (1.4) \quad \pi_{\Lambda, f}(T) \ll \frac{N_{\Lambda}(T)}{(\log T)^{t(f)}}. \]

We also obtain the following lower bound for the number of points \( x \in \Lambda \) for which \( f \) has at most a fixed number of prime factors.

**Theorem 1.7.** Let \( \Lambda \) be a subgroup of \( \text{SL}(2, \mathbb{Z}) \) which is Zariski dense in \( \text{SL}_2 \) and let \( f \in \mathbb{Z}[x_{ij}] \) be weakly primitive with \( t(f) \) irreducible factors. Then there is an \( r < \infty, \) which can be given explicitly in terms of \( \epsilon(\Lambda) \) in theorems 1.1 and 1.4, such that

\[ (1.5) \quad |\{x \in \Lambda; |x| \leq T, \text{ and } f(x) \text{ has at most } r \text{ prime factors}\}| \gg \frac{N_{\Lambda}(T)}{(\log T)^{t(f)}}. \]

2. Generalization of Selberg’s 3/16 theorem when \( \delta > 1/2 \)

Being a subgroup of finite index in \( \Lambda(1), \Lambda(q) \) has the same bottom of the spectrum, \( \lambda_0(\Lambda(q)\backslash \mathbb{H}) = \lambda_0(\Lambda(1)\backslash \mathbb{H}). \) As in section 2 of [11], we have that for \( q \) large enough \( \Lambda(1)/\Lambda(q) \cong \text{SL}_2(\mathbb{Z}/q\mathbb{Z}). \) Let \( S = \{A_1, \ldots, A_k\}, \) and let \( S_q \) be the natural projection of \( S \) modulo \( q. \)
THEOREM 1.7 in [4] implies that if $\Lambda = \langle S \rangle$ is non-elementary, then $G_q = G(SL_2(\mathbb{Z}/q\mathbb{Z}), S_q)$ is a family of expanders. Consider the space $H(q)$ of vector-valued functions $F$ on $\mathcal{F}(1)$, satisfying

\[ F(\gamma z) = R_q(\gamma)F(z), \]

for $\gamma \in \Lambda(1)/\Lambda(q) \cong SL_2(\mathbb{Z}/q\mathbb{Z})$, where $R_q(\gamma)$ denotes the regular representation of $SL_2(\mathbb{Z}/q\mathbb{Z})$; we denote by $\langle, \rangle$ the inner product on this space and by $\|\|$ the associated norm. Denoting by $H_0(q)$ the subspace of functions in $H(q)$ orthogonal to $\varphi_0$, the eigenfunction corresponding to $\lambda_0$, the assertion of Theorem 1.1 is equivalent to existence of $c > 0$ such that

\[ \int_{\mathcal{F}} \|\nabla F\|^2d\mu \geq \lambda_0 + c \]

for all $F \in H_0(q)$.

Applying Theorem 1.7 in [4] for each $z \in \mathcal{F}(1)$ implies that there is $\varepsilon > 0$, depending only on $S$, such that for all $F \in H_0(q)$, we have

\[ \|F(\gamma z) - F(z)\| \geq \varepsilon\|F(z)\| \text{ for some } \gamma \in S. \]

Let $f = \|F\|$, and decompose it as

\[ f = a\varphi_0(z) + b(z), \]

where

\[ \int_{\mathcal{F}} \varphi_0(z)\overline{b(z)}d\mu(z) = 0 \]

and

\[ \int_{\mathcal{F}} |f|^2d\mu = a^2 + \int_{\mathcal{F}} |b|^2d\mu = 1. \]

Write

\[ F(z) = (F_1(z), \ldots, F_N(z)), \]

where $N = |SL_2(\mathbb{Z}/q\mathbb{Z})|$. Since

\[ \nabla \left( \sum_{j=1}^{N} |F_j(z)|^2 \right)^{\frac{1}{2}} = \begin{cases} \frac{\sum_{j=1}^{N} F_j(z)\overline{\nabla F_j(z)}}{\left(\sum_{j=1}^{N} |F_j(z)|^2\right)^{\frac{1}{2}}} & \text{if } \sum_{j=1}^{N} |F_j(z)|^2 \neq 0 \\ 0 & \text{otherwise,} \end{cases} \]

we have

\[ \|\nabla F\|^2(z) \geq \|\nabla f\|^2(z) = |\nabla f|^2(z). \]
Consequently we obtain:

\[
\int_\mathcal{F} \| \nabla F \|^2 d\mu \geq \int_\mathcal{F} |F|^2 d\mu = \int_\mathcal{F} |F|^2 d\mu = \int_\mathcal{F} \langle \Delta f, f \rangle d\mu
\]

\[
= a^2 \lambda_0 + \langle \Delta b, b \rangle \geq a^2 \lambda_0 + \lambda_1 \int_\mathcal{F} |b|^2 d\mu \geq \lambda_0 + (\lambda_1 - \lambda_0) \int_\mathcal{F} |b|^2 d\mu.
\]

By a theorem of Lax and Phillips [17] there are only finitely many discrete eigenvalues of \( \Lambda \) in \( [0, \frac{1}{4}] \); consequently

\[
\lambda_1 - \lambda_0 \geq c_1 > 0.
\]

Therefore, as soon as \( \int_\mathcal{F} |b|^2 d\mu > \varepsilon_1 > 0 \), we have that

\[
\int_\mathcal{F} |\nabla F|^2 d\mu \geq \lambda_0 + c_1 \varepsilon_1.
\]

Now consider the case of \( \int_\mathcal{F} |b|^2 d\mu = 0 \). We can assume that \( a = 1 \) and write \( F(z) = u(z)\varphi_0(z) \), with \( u(z) = (u_1(z), \ldots, u_N(z)) \), where \( N = |\text{SL}_2(\mathbb{Z}/q\mathbb{Z})| \). Now

\[
\|u(z)\| = \sum_{j=1}^N |u_j|^2(z) = 1
\]

implies

\[
\sum_{j=1}^N u_j \frac{\partial u_j}{\partial x} = \sum_{j=1}^N u_j \frac{\partial u_j}{\partial x} = 0,
\]

and since

\[
\frac{\partial (\varphi_0 u_j)}{\partial x} = u_j \frac{\partial \varphi_0}{\partial x} + \varphi_0 \frac{\partial u_j}{\partial x},
\]

\[
\frac{\partial (\varphi_0 u_j)}{\partial y} = u_j \frac{\partial \varphi_0}{\partial y} + \varphi_0 \frac{\partial u_j}{\partial y},
\]
we have that
\[ \|\nabla \varphi_0 u\|^2 = \left( \frac{\partial \varphi_0}{\partial x} \right)^2 \sum_{j=1}^{N} u_j^2 + \varphi_0^2 \sum_{j=1}^{N} \left( \frac{\partial u_j}{\partial x} \right)^2 + \left( \frac{\partial \varphi_0}{\partial y} \right)^2 \sum_{j=1}^{N} u_j^2 + \varphi_0^2 \sum_{j=1}^{N} \left( \frac{\partial u_j}{\partial y} \right)^2 + 2 \varphi_0 \frac{\partial \varphi_0}{\partial x} \sum_{j=1}^{N} u_j \frac{\partial u_j}{\partial x} + 2 \varphi_0 \frac{\partial \varphi_0}{\partial y} \sum_{j=1}^{N} u_j \frac{\partial u_j}{\partial y} = |\nabla \varphi_0|^2 + \varphi_0^2 \|\nabla u\|^2. \] (2.12)

Consequently,
\[ \int_{\mathcal{F}} \|\nabla F\|^2 d\mu = \int_{\mathcal{F}} |\nabla \varphi_0|^2 + \varphi_0^2 \|\nabla u\|^2 d\mu = \int_{\mathcal{F}} |\varphi_0|^2 d\mu + \int_{\mathcal{F}} \varphi_0^2 \|\nabla u\|^2 d\mu \]
\[ \int_{\mathcal{F}} |\varphi_0|^2 d\mu + \int_{\mathcal{F}} \varphi_0^2 \|\nabla u\|^2 d\mu \geq \lambda_0 + \int_{\mathcal{F}} \varphi_0^2 \|\nabla u\|^2 d\mu. \] (2.13)

Our aim now is to show that
\[ \int_{\mathcal{F}} \varphi_0^2 \|\nabla u\|^2 d\mu \geq c_2 > 0. \] (2.14)

To that end we assume that
\[ \int_{\mathcal{F}} \varphi_0^2 \|\nabla u\|^2 d\mu < \kappa \] (2.15)

and will obtain a contradiction for sufficiently small \( \kappa \) (\( \kappa_j \) below are of the form \( a_j \cdot \kappa \) for suitable constants \( a_j \)). Consider the fundamental domain \( \mathcal{F}(1) = \Lambda(1) \backslash \mathbb{D} \). Its boundary, \( \partial \mathcal{F}(1) \), consists of finitely many geodesic arcs \( \{ l_i \} \) splitting into pairs \( l_j, l'_j \) in such a way that there is \( \gamma_j \in S \) so that \( l_j = \gamma_j l'_j \); \( \gamma_j \) are distinct and generate \( \Lambda(1) \). Further, we have decomposition of the following form:
\[ \mathcal{F}(1) = \mathcal{K}(1) \cup \bigcup_{i \in Cu(1)} \text{cusp}_i \cup \bigcup_{j \in Fl(1)} \text{flare}_j \]
where
(1) \( \mathcal{K}(1) \) is relatively compact in \( \mathbb{D} \)
(2) $Cu(1)$ is a set of cusps of $\mathcal{F}(1)$. Each cusp $i$ is isometric to a standard cuspidal fundamental domain $P(Y_i)$ of the form

$$P(Y) = \{ z = x + iy \mid 0 < x < 1, y > Y \},$$

based on a horocycle

$$h_Y = \{ x + iy \mid y = Y \}.$$

(3) $Fl(1)$ is a set of flares of $F(1)$. Each flare $j(\alpha)$ is isometric to a standard hyperbolic fundamental domain $F(\alpha)$ of the form

$$F(\alpha) = \{ z : 1 < |z| < \exp(\beta); 0 < \arg(z) < \alpha \},$$

where $\alpha < \frac{\pi}{2}$.

Since $\varphi_0 \in L^2(\mathcal{F}(1))$, we have that

$$\int_{\mathcal{K}} |\varphi_0|^2d\mu \geq c_3 \int_{\mathcal{F}} |\varphi_0|^2d\mu$$

for some $c_3 > 0$, and therefore (2.16) implies that

$$\frac{\int_{\mathcal{K}} \varphi_0^2 \|\nabla u\|^2d\mu}{\int_{\mathcal{K}} |\varphi_0|^2d\mu} \leq \kappa_1.$$ (2.17)

We recall the definition of Fermi coordinates. Let $\eta$ be the geodesic in the hyperbolic plane parameterized with the unit speed in the form

$$t \rightarrow \eta(t) \in \mathbb{H}^2 \quad t \in \mathbb{R}.$$ Then $\eta$ separates $\mathbb{H}^2$ into two half-planes: a left hand side and a right hand side of $\eta$. For each $p \in \mathbb{H}^2$ we have the directed distance $\rho$ from $p$ to $\eta$. There exists a unique $t$ such that the perpendicular from $p$ to $\eta$ meets $\eta$ at $\eta(t)$. Now $(\rho, t)$ is a pair of Fermi coordinates of $p$ with respect to $\eta$. In these coordinates the metric tensor is

$$ds^2 = d\rho^2 + \cosh^2 \rho dt^2.$$ (2.18)

Introduce Fermi coordinates based on the bounding geodesics $l_j$, and use them to foliate $\mathcal{K}$. By compactness, using (2.17), we can find $z \in \mathcal{K}$ and $\delta > 0$ such that

$$\int_{B(z, \delta)} |\varphi_0|^2 > c_4 > 0,$$ (2.19)

and for all $j = 1, \ldots, k$

$$\frac{\int_{T_j(\delta)} \varphi_0^2 \|\nabla u\|^2d\mu}{\int_{T_j(\delta)} |\varphi_0|^2d\mu} < \kappa_2,$$ (2.20)

where $T_j(\delta)$ is a tube lying in $\mathcal{K}$ and containing $B(z, \delta)$ along the perpendicular to $l_j$. 

Each $T$ is of the form $[-\delta, \delta] \times [\rho_{1,j}, \rho_{2,j}]$ in the appropriate Fermi coordinates. Rewriting (2.20) in Fermi coordinates (2.18), and using the fact that
\[
\left(\frac{\partial u_j}{\partial \rho}\right)^2 + \left(\frac{\partial u_j}{\partial t}\right)^2 \geq \left(\frac{\partial u_j}{\partial \rho}\right)^2,
\]
by Fubini’s Theorem we obtain
\[
(2.21) \quad \int_{T_j(\delta)} \varphi_0^2 \|\nabla u\|^2 d\mu \geq 2\delta \int_{\rho_{1,j}}^{\rho_{2,j}} \varphi_0^2 \|u'(\rho)\|^2 \cosh(\rho) d\rho.
\]
Let $L$ denote the maximal length of the tubes $T_j$. Using the fact that if $|u(\rho_1) - u(\rho_2)| \geq C$ and $\rho_1 - \rho_2 \leq L$ then \(\int_{\rho_1}^{\rho_2} |u'(\rho)|^2 d\rho > C^2 / L\) (since
\[
C^2 \leq \left(\int_{\rho_1}^{\rho_2} u'(\rho) d\rho\right)^2 \leq \left(\int_{\rho_1}^{\rho_2} 1 d\rho\right) \left(\int_{\rho_1}^{\rho_2} |u'(\rho)|^2 d\rho\right),
\]
we obtain that (2.20) implies that for all $j = 1, \ldots, k$ we have
\[
(2.22) \quad \int_{B(z,\delta)} \varphi_0^2 \|u(\gamma_j z) - u(z)\| d\mu(z) < \kappa_3 \int_{B(z,\delta)} \varphi_0^2 d\mu(z).
\]
On the other hand, since $F(z) = u(z)\varphi_0(z)$ and $\varphi_0(\gamma z) = \varphi_0(z)$ for all $\gamma \in \text{SL}_2(\mathbb{Z}/q\mathbb{Z})$, (2.3) implies that there is $\varepsilon(S) > 0$ independent of $q$, such that
\[
(2.23) \quad \|u(\gamma z) - u(z)\| > \varepsilon(S) \quad \text{for some } \gamma \in S.
\]
Applying mean-value theorem, we see that (2.22) implies a contradiction with (2.23) once $\kappa$ is small enough depending on $\varepsilon(S)$; consequently we have proved the validity of (2.14) and the proof of Theorem 1.1 is complete.

The adaption of the preceding argument to proving the implication $1 \Rightarrow 2$ of theorem 1.2 is straightforward, as is the generalization of this result to higher dimensional hyperbolic spaces: the theorem of Lax and Phillips, of which we made crucial use in the first part of the argument, holds for geometrically finite subgroups of $\text{SO}(n,1)$ with Hausdorff dimension of the limit set greater than $n/2$; the second part of the argument proceeds as above by restricting to compact part of the fundamental domain and foliating it using Fermi coordinates. In particular, by combining the $\mathbb{H}^d$ analogue of Theorem 1.2 with 37 and Theorem 6.3 in 4 we obtain the following theorem which has applications to integral Apollonian packings 10, 15, 30.
Theorem 2.1. Let $\Lambda$ be a geometrically-finite subgroup of $\text{SL}_2(\mathbb{Z}[\sqrt{-1}])$ with $\delta(\Lambda) > 1$ and such that the traces of elements of $\Lambda$ generate the field $\mathbb{Q}(\sqrt{-1})$. There is $\varepsilon = \varepsilon(\Lambda) > 0$ such that
\[ \lambda_1(\Lambda(A)) \geq \lambda_0(\Lambda(A)) + \varepsilon \]
as $A$ varies over squarefree ideals in $\mathbb{Z}[\sqrt{-1}]$.

3. Counting lattice points for $\delta > \frac{1}{2}$

Recall that the Poincaré upper half-plane model is the following subset of the complex plane $\mathbb{C}$:
\[ \mathbb{H}^2 = \{ z = x + iy \in \mathbb{C} \mid y > 0 \} , \]
with the hyperbolic metric
\[ ds^2 = \frac{1}{y^2}(dx^2 + dy^2) . \]
The distance function on $\mathbb{H}^2$ is explicitly given by
\[ \rho(z, w) = \log \frac{|z - \bar{w}| + |z - w|}{|z - \bar{w}| - |z - w|} . \]
We will use the following expression:
\[ \cosh \rho(z, w) = 1 + 2u(z, w) , \]
where
\[ u(z, w) = \frac{|z - w|^2}{4\Im z\Im w} . \]
The ring $M_2(\mathbb{R})$ of two by two real matrices is a vector space with inner product given by
\[ \langle g, h \rangle = \text{trace}(gh^t) . \]
One easily checks that $\|g\| = \langle g, g \rangle^{\frac{1}{2}}$ is norm in $M_2(\mathbb{R})$ and that
\[ \|g\|^2 = a^2 + b^2 + c^2 + d^2 \quad \text{for} \quad g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} . \]
By taking $z = w = i$ in (3.4) we obtain that
\[ \|g\|^2 = a^2 + b^2 + c^2 + d^2 = 4u(\text{gi}, i) + 2 . \]
Now the result of Lax and Phillips [17] is as follows. Let
\[ N_\Lambda(T; z, w) = \# \{ \gamma \in \Lambda : \rho(z, \gamma w) \leq T \} . \]
Suppose \( \delta > \frac{1}{2} \) and write \( \lambda_j = \delta_j (1 - \delta_j) \); \( \delta_0 = \delta \). Denoting the eigenfunctions corresponding to \( \lambda_j \) by \( \varphi_j \) we have

\[
|N(T; z, w) - \sum_j c_j \varphi_j(z) \varphi_j(w) e^{\delta_j T}| = O(T^{5/6} e^{T/2}).
\]

Turning to congruence subgroups \( \Lambda(q) \) we have, using the methods of [17], that

\[
|N_{\Lambda(q)}(T; z, w) - \sum_j c_j \varphi_{j,q}(z) \varphi_{j,q}(w) e^{\delta_{j,q} T}| = O(q^3 T^{5/6} e^{T/2}),
\]

where implied constant is independent of \( q \).

The base eigenfunction for \( \Lambda(q) \), normalized to have \( L^2 \) norm one, is given by

\[
\varphi_{0,q} = \frac{1}{|SL_2(\mathbb{Z}/q\mathbb{Z})|} \varphi_{0,1}.
\]

Combining Theorem 1.1 with (3.9) and (3.2), (3.6) we obtain \( \varepsilon_1 > 0 \) depending on \( \Lambda \) such that for any \( g \in SL_2(q) \) we have

\[
|\{ \gamma \in \Lambda \mid \| \gamma \| \leq T \text{ and } \gamma \equiv g \mod q \}| = \frac{c \Lambda T^{2\delta}}{|SL_2(q)|} + O(q^3 T^{2\delta - \varepsilon_1}),
\]

establishing Theorem 1.3.

4. Shifts and thermodynamic formalism

When \( \delta \leq \frac{1}{2} \) the \( L^2 \) spectral theory of Lax and Phillips [17] is not available and we use symbolic dynamics approach, in particular the work of Lalley [16]. In this section we review the key necessary notions and results pertaining to shifts of finite type.

A shift of finite type is defined as follows. Let \( A \) be an irreducible, aperiodic \( l \times l \) matrix of zeroes and ones, called the transition matrix. Define \( \Sigma \) to be the space of all sequences taking values in the alphabet \{1, 2, \ldots, l\} with transitions allowed by \( A \), that is

\[
\Sigma = \{ x \in \prod_{n=0}^{\infty} \{1, \ldots, l\} : A(x_n, x_{n+1}) = 1 \ \forall n \}.
\]

The space \( \Sigma \) is compact and metrizable in the product topology. Define the forward shift \( \sigma : \Sigma \to \Sigma \) by \( (\sigma x)_n = x_{n+1} \) for \( n \geq 0 \).

Let \( C(\Sigma) \) be the space of continuous, complex-valued functions on \( \Sigma \). For \( f \in C(\Sigma) \) and \( 0 < \rho < 1 \) define

\[
\text{var}_n f = \sup \{ |f(x) - f(y)| : x_j = y_j \text{ for } 0 \leq j \leq n \};
\]
\[ |f|_\rho = \sup_{n \geq 0} \text{var}_n(f)/\rho^n; \]

\[ \mathcal{F}_\rho = \{ f \in C(\Sigma) : |f|_\rho < \infty \} \]

Elements of \( \mathcal{F}_\rho \) are called Hölder continuous functions. The space \( \mathcal{F}_\rho \), when endowed with the norm \( \| \cdot \|_\rho = |\cdot|_\rho + \| \cdot \|_\infty \) is a Banach space.

For \( f, g \in C(\Sigma) \) define the transfer operator \( \mathcal{L}_fg \in C(\Sigma) \) by

\[ \mathcal{L}_fg(x) = \sum_{y: \sigma y = x} e^{f(y)} g(y). \]

For each \( \rho \in (0, 1) \) and \( f \in \mathcal{F}_\rho \), \( \mathcal{L}_f : \mathcal{F}_\rho \to \mathcal{F}_\rho \) is a continuous linear operator; if \( f \) is real-valued then \( \mathcal{L}_f \) is positive.

Denoting

\[ S_n f = f + f \cdot \sigma + \ldots + f \cdot \sigma^{n-1}, \]

we have

\[ (\mathcal{L}_f^n g)(x) = \sum_{y: \sigma^n y = x} e^{S_n f(y)} g(y). \]

The following result is due to Ruelle; a proof can be found in \([23]\) or \([27]\).

**Theorem 4.1.** Let \( f \in \mathcal{F}_\rho \) be a real-valued function.

1. There is a simple eigenvalue \( \lambda_f > 0 \) of \( \mathcal{L}_f : \mathcal{F}_\rho \to \mathcal{F}_\rho \) with strictly positive eigenfunction \( h_f \).
2. The rest of the spectrum of \( \mathcal{L}_f \) is contained in \( \{ z \in \mathbb{C} : |z| \leq \lambda_f - \varepsilon \} \) for some \( \varepsilon > 0 \).
3. There is a Borel probability measure \( \nu_f \) on \( \Sigma \) such that \( \mathcal{L}_f \nu_f = \lambda_f \nu_f \).
4. If \( h_f \) is normalized so that \( \int h_f d\nu_f = 1 \) then for every \( g \in C(\Sigma) \)

\[ \lim_{n \to \infty} \| \lambda_f^{-n} \mathcal{L}_f^n g - (\int g d\nu_f) h_f \|_\infty = 0 \]

5. There exist constants \( C_1, \varepsilon_1 \) such that for all \( g \in \mathcal{F}_\rho \) and for all \( n \)

\[ \| \lambda_f^{-n} \mathcal{L}_f^n g - (\int g d\nu_f) h_f \|_\rho \leq C_1 (1 - \varepsilon_1)^n \| g \|_\rho. \]

The pressure functional is defined by

\[ P(f) = \sup_\nu \int f d\nu + H_\nu(\sigma), \]
where the supremum is taken over the set of \( \sigma \)-invariant probability measures and \( H_\nu(\sigma) \) is the measure theoretic entropy of \( \sigma \) with respect to \( \nu \). We have (see [23] or [27])

\[
P(f) = \log \lambda_f.
\]

A measure \( \mu \) is called the equilibrium state or the Gibbs measure with the potential \( f \) if

\[
\int f \, d\mu + H_\mu(\sigma) = P(f).
\]

For \( f \in F_\rho \) Gibbs measure \( \mu_f \) is the unique \( \sigma \)-invariant probability measure on \( \Sigma \) for which there exist constants \( 0 < C_1 \leq C_2 < \infty \) such that

\[
C_1 \leq \frac{\mu_f\{y \in \Sigma : y_i = x_i, 0 \leq i < n\}}{\lambda_f^n \exp\{S_n f(x)\}} \leq C_2.
\]

As will become clear in the next section, the analyticity properties of the map \( z \to L_z f, z \in \mathbb{C} \) will play crucial role in the proof. For \( f \in F_\rho \) fixed, real-valued function, such that \( S_m f \) is strictly positive for some \( m \), the quantities \( L_z f, \lambda_z f, h_z f, \nu_z f \) will be abbreviated by \( L_z, \lambda_z, h_z, \nu_z \).

5. Resolvent of transfer operator and lattice count problem

Let \( \Lambda \) be a Fuchsian group with no parabolic elements (this condition is automatically satisfied in the case \( \delta(\Lambda) \leq \frac{1}{2} \) — see [17]), generated by \( k \) elements \( g_1, \ldots, g_k \subset \text{SL}_2(\mathbb{Z}) \). We identify \( \Lambda \) with \( \Sigma_* \), defined as the set of finite sequences in the alphabet \( \{g_1, g_1^{-1}, \ldots, g_k, g_k^{-1}\} \) (\( l = 2k \)) with admissible transitions. According to Series [33], this may be done so as to obtain a shift of finite type.

Let \( w \in \mathbb{H}(= \mathbb{D}) \), and suppose it is not a fixed point for any \( \gamma \in \Lambda \); let \( d_H \) denote hyperbolic distance. For \( x = x_1, \ldots, x_m \in \Sigma_*(= \Lambda) \) define

\[
(5.1) \quad \tau(x) = d_H(0, x_1 \ldots x_m w) - d_H(0, x_2 \ldots x_m w).
\]

The left shift \( \sigma \) on \( \Sigma \) corresponds to the Nielsen map (see [33]) \( F : L \to L \), where \( L \) denotes the limit set of \( \Lambda \).

Recalling that

\[
(5.2) \quad S_n \tau = \tau + \tau \cdot \sigma + \cdots + \tau \cdot \sigma^{n-1},
\]

we have

\[
(5.3) \quad S_n \tau(x) = d_H(0, x_1 \ldots x_n x_{n+1} \ldots w) - d_H(0, x_{n+1} \ldots w).
\]
For $a \in \mathbb{R}$, $x \in \Sigma_*$, $\phi : \Sigma_* \to \mathbb{R}$, let
\begin{equation}
N(a, x) = \sum_{n=0}^{\infty} \sum_{y : \sigma^n y = x} \phi(y) 1_{\{S_n \tau(y) \leq a\}}.
\end{equation}

Clearly
\begin{equation}
N(a, x) = \sum_{y \in \Lambda, d_H(0, yxw) - d_H(0, xw) \leq a} \phi(yx),
\end{equation}
where in the summation $y$ is restricted so as to make $yx$ admissible.

In particular, for $\phi = 1$
\begin{equation}
N(a, x) = |\{\gamma \in \Lambda | d_H(i, \gamma xw) - d_H(i, xw) \leq a\}|.
\end{equation}

Returning to (5.4), one has the renewal equation
\begin{equation}
N(a, x) = \sum_{\sigma(x') = x} N(a - \tau(x'), x') + \phi(x) 1_{\{a \geq 0\}}
\end{equation}
(cf. [16, (2.2)]).

The link with the transfer operator comes by taking the Laplace transform of (5.6). Defining for $\Re z < -C$
\begin{equation}
F(z, x) = \int_{-\infty}^{\infty} e^{az} N(a, x) da,
\end{equation}
equation (5.6) gives the relation
\begin{equation}
F(z, x) = \sum_{\sigma(x') = x} e^{z \tau(x')} F(z, x') + \frac{\phi(x)}{z}.
\end{equation}
Thus we have
\begin{equation}
(I - L_z) F(z, x) = \frac{\phi(x)}{z}.
\end{equation}

This leads us to the study of the resolvent $(I - L_z)^{-1}$. Before stating the results of Lalley [16] and Naud [21] for $L_z|\mathcal{F}_\rho(\Sigma)$ (Theorem 5.1 below) we recall the following reinterpretation of the Hausdorff dimension of the limit set in terms of the pressure functional (see [23] or [27]). Because $\tau$ is eventually positive, the variational principle implies (see [23] or [27]) that the pressure functional $P(-x\tau)$ is strictly decreasing and has unique positive zero. Define $\delta$ by $P(-\delta \tau) = 0$, that is,
\begin{equation}
\lambda_{-\delta} = 1.
\end{equation}

**Theorem 5.1.** (1) There is $\varepsilon > 0$ such that for $\Re z < -\delta + \varepsilon$, $z \not\in U$ ($U$ a suitable neighborhood of $-\delta$), we have
\begin{equation}
\|L_z|\mathcal{F}_\rho(\Sigma)\|_\rho \lesssim |\Im z|^2 e^{-\varepsilon n}.
\end{equation}
(2) For $z \in U$ decompose on $F_{\rho}(\Sigma)$

\[(5.12) \quad \mathcal{L}_z = \lambda_z (\nu_z \otimes h_z) + \mathcal{L}'', \]

(where $z \rightarrow \lambda_z, z \rightarrow h_z, z \rightarrow \nu_z$ are holomorphic extensions to $U$, satisfying

\[
\mathcal{L}_z h_z = \lambda_z h_z, \quad \mathcal{L}_z^* \nu_z = \lambda_z \nu_z, \quad \int h_z d\nu_z = 1.
\]

Then

\[(5.13) \quad \| (\mathcal{L}''_z)^n \|^\rho < e^{-\varepsilon n} \quad \text{for} \quad z \in U.\]

Part 1 follows from the discussion in Lalley [16, p. 25] (in the case when $\tau$ is non-lattice) and Theorem 2.3 in Naud [21] to provide (5.11) when $|\Im z|$ is large. Naud’s work build crucially on the approach of Dolgopyat [8]. Note that Lalley does not give explicit estimates on $\|\mathcal{L}''_z\|$ for $\Re z = -\delta$ and $\Im z \rightarrow \infty$ and certainly no bound of the strength of Theorem 2.3 in Naud [21].

Part 2 is Proposition 7.2. in [16].

6. LATTICE COUNT IN CONGRUENCE SUBGROUPS FOR $\delta \leq \frac{1}{2}$

In this section we modify the setup discussed in the preceding two sections to the setting of congruence subgroups of $\Lambda$ — the modification is analogous to the one preformed in the case $\delta > \frac{1}{2}$.

Fix modulus $q$ such that $\pi_q(\Lambda) = \SL_2(q)$. Instead of considering functions on $\Sigma$ (as in Lalley [16]) we consider functions on $\Sigma \times \SL_2(q)$.

For $f \in C(\Sigma \times \SL_2(q))$ define

\[
\| f \|_\infty = \max_x \left( \sum_{g \in \SL_2(q)} |f(x, g)|^2 \right)^{\frac{1}{2}};
\]

\[
\text{Var}_n f = \sup \left\{ \left( \sum_g |f(x, g) - f(y, g)|^2 \right)^{\frac{1}{2}} \mid x_j = y_j \text{ for } j \leq n \right\};
\]

\[
|f|_\rho = \sup_n \frac{\text{Var}_n(f)}{\rho^n}.
\]

Let $F_{\rho} = F_{\rho}(\Sigma \times \SL_2(q))$ denote the space of $\rho$-Lipschitz continuous functions with the norm

\[
\| \cdot \|_{\rho} = \| \cdot \|_\infty + \| \cdot \|_\rho.
\]
Let $\tau : \Sigma_* \to \mathbb{R}$ be given by (5.1) and consider the “congruence transfer operator” $M_z = M_{z\tau}$ on $F_p(\Sigma \times SL_2(q))$:

(6.1) $M_z f(x, g) = \sum_{i=1}^{l} e^{z\tau(i, x)} f(i, x; g, g_i g_i)$,

where $z \in \mathbb{C}$ and the summation is restricted so as to make $(i, x)$ admissible.

Thus our $M_z$ differs from the one considered in [16] in that it acts on functions on $\Sigma \times SL_2(q)$ rather than on functions on $\Sigma$: the reason behind this difference is the same as in the proof of the spectral gap when $\delta(\Lambda) > \frac{1}{2}$.

We have

$$M_z^2 f(x, g) = \sum_{i_1=1}^{l} e^{z\tau(i_1, x)} (M_z f)((i_1, x), g_{i_1} g_i g_i),$$

and in general for the $n$-th iterate we have

(6.2) $M_z^n f(x; g) = \sum_{i_1, \ldots, i_n=1}^{l} e^{z\tau(i_1, \ldots, i_n, x) + \tau(i_{n-1}, \ldots, i_1, x) + \cdots + \tau(i_1, x))} f((i_n \ldots i_1, x); g_{i_n} \ldots g_{i_1} g_i g_i),$

where again the summation is restricted to admissible words.

From Ruelle’s theorem (Theorem 4.1) it follows that

(6.3) $\sum_{i_1, \ldots, i_n=1}^{l} e^{Rz(\tau(i_n, \ldots, i_1, x) + \tau(i_{n-1}, \ldots, i_1, x) + \cdots + \tau(i_1, x))} \sim \lambda_{Rz}^{n}$

for large $n$.

Let $\varphi$ be a function on $SL_2(q)$. Returning to (5.4), (5.5) we let

(6.4) $N(a, x) = \sum_{y \in \Lambda, d_H(0, yxw) - d_H(0, xw) \leq a} \varphi(\pi_q(y))$

and $F(z, x)$ its Laplace transform defined by (5.7).

Then

(6.5) $F(z, x) = f(z, x, \pi_q(x))$,

where $f(z, x, g)$ satisfies

(6.6) $(1 - M_z)f = \frac{1 \otimes \varphi}{z}$.
and $\mathcal{M}_x$ is the congruence transfer operator introduced above (note that obviously $1 \otimes \varphi$ is in $\mathcal{F}_q(\Sigma \times \text{SL}_2(q))$).

Our aim is to evaluate

$$N(a) = \sum_{y \in \Lambda, d_H(0, yw) - d_H(0, w) \leq a} \varphi(\pi_q(y)),$$

which gives the sum of $\varphi$ on the mod $q$ reduction of the hyperbolic ball

$$\{y \in \Lambda | d_H(0, yw) - d_H(0, w) \leq a\}.$$

Our goal now is to obtain the appropriate extension of Theorem 5.1 to the setting of congruence subgroup. As is to be expected, it is at this point that expansion property will play a crucial role.

**7. Expansion and $L^2$ Flattening**

Let $\mu$ be a symmetric measure on $G = \text{SL}_2(p)$ (for the sake of exposition we first consider the simpler case of prime $p$) and consider the convolution map $T : L^2(G) \to L^2(G)$, given by $\varphi \to \mu * \varphi$. Decomposing the regular representation of $G$ into irreducible representations if follows from the result of Frobenius [9] that each eigenvalue $\lambda$ of the convolution restricted to $L^2_0(G)$ occurs with multiplicity at least $\frac{p - 1}{2}$.

Trace calculation yields therefore

$$|G|\|\mu\|_2^2 = \sum_{x \in G} \langle T^2 \delta_x, \delta_x \rangle \geq \frac{p - 1}{2} \lambda^2.$$

Hence

$$(7.1) \quad |\lambda| \leq \sqrt{\frac{2}{p - 1}} \|\mu\|_2 |G|^{\frac{1}{2}}.$$

Recall also the $L^2$-flattening lemma proven in [3]. Let $\mu \in \mathcal{P}(G)$ satisfy

$$(7.2) \quad \|\mu\|_\infty < p^{-\tau}$$

for some $\tau > 0$ and also

$$(7.3) \quad \mu(aG_1) < p^{-\tau}$$

for all cosets of proper subgroups $G_1$ of $G$. Given $\kappa > 0$ there is $l = l(\tau, x) \in \mathbb{Z}_+$ such that

$$(7.4) \quad \|\mu^{(l)}\|_2 < |G|^{-1/2 + \kappa}.$$

Denote $\mu'(x) = \mu(x^{-1})$. Since $\mu * \mu'$ also satisfies (7.2), (7.3) we have by (7.4) that

$$(7.5) \quad \|\mu' \ast \mu\|_2 \leq |G|^{-1/2 + \kappa}.$$
Consider the convolution operator $T \varphi = \mu' \ast \mu \ast \varphi$ and let $\lambda$ be an eigenvalue of $T$ on $L^2_0(G)$. Hence $\lambda^l$ is an eigenvalue of $T^l$ on $L^2_0(G)$ and applying (7.1) with $\mu$ replaced by $(\mu' \ast \mu)^{(l)}$ implies

$$|\lambda|^l \leq \sqrt{\frac{2}{p-1} \|(\mu' \ast \mu)^{(l)}\|_2 |G|^l} < \sqrt{\frac{2}{p-1} |G|^\kappa < p^{-\frac{1}{4}}}$$

if we take $\kappa < \frac{1}{4}$. Consequently

(7.6) \quad |\lambda| < p^{-\frac{1}{4}}.

This means that if $\varphi \in L^2_0(G)$, then

$$\|\mu' \ast \mu \ast \varphi\|_2 \leq p^{-\frac{1}{4}} \|\varphi\|_2$$

and hence

(7.7) \quad \|\mu \ast \varphi\|_2 \leq p^{-\frac{1}{4}} \|\varphi\|_2.

We proved that if $\mu \in \mathcal{P}(G)$ satisfies (7.2), (7.3) for some $\tau > 0$, then

(7.8) \quad \|\mu \ast \varphi\|_2 \leq p^{-\tau'} \|\varphi\|_2, \quad \varphi \in L^2_0(G)

for some $\tau' > 0$. Therefore if $\mu \in \mathcal{M}_+(G)$ satisfies

(7.9) \quad \|\mu\|_\infty < p^{-\tau} \|\mu\|_1

and

(7.10) \quad |\mu|(aG_1) < p^{-\tau} \|\mu\|_1

for cosets of proper subgroups $G_1$ then

(7.11) \quad \|\mu \ast \varphi\|_2 \leq p^{-\tau} \|\mu\| \|\varphi\|_2, \quad \varphi \in L^2_0(G).

More generally, let $\mu \in \mathcal{M}(G)$ and decompose $\mu = \mu_+ + \mu_-$. Estimate

$$\|\mu \ast \varphi\|_2 \leq \|\mu_+ \ast \varphi\|_2 + \|\mu_- \ast \varphi\|_2.$$

Assume $\mu$ satisfies (7.9) and (7.10). If $\|\mu_+\| > p^{-\frac{3}{4}} \|\mu\|$, we have

$$\|\mu_+\|_\infty \leq \|\mu\|_\infty < p^{-\frac{3}{4}} \|\mu_+\|_1 \quad \text{and} \quad \mu_+(aG_1) < p^{-\frac{3}{4}} \|\mu_+\|_1$$

and (7.11) implies that for $\varphi \in L^2_0(G)$ we have

$$\|\mu_+ \ast \varphi\|_2 \leq p^{-\tau'} \|\mu_+\| \|\varphi\|_2 \leq p^{-\tau'} \|\mu\| \|\varphi\|_2.$$ If $\|\mu_+\| \leq p^{-\frac{3}{4}} \|\mu\|$, then obviously

$$\|\mu_+ \ast \varphi\|_2 \leq \|\mu_+\| \|\varphi\|_2 \leq p^{-\frac{3}{4}} \|\mu\| \|\varphi\|_2.$$ Hence (7.11) holds.

The same considerations apply for $\mu \in \mathcal{M}_C(G)$; consequently we obtain the following result.
Lemma 1. Given \( \kappa > 0 \), there is \( \kappa' > 0 \) such that if \( \mu \in \mathcal{M}_C(G) \) satisfies
\[
\|\mu\|_\infty < p^{-\kappa}\|\mu\|_1
\]
and
\[
|\mu|(aG_1) < p^{-\kappa}\|\mu\|_1
\]
for cosets of proper subgroups \( G_1 \) of \( G \), then
\[
\|\mu\ast\varphi\|_2 \leq C_p^{-\kappa'}\|\mu\|_1\|\varphi\|_2 \quad \text{for } \varphi \in L^2_0(G).
\]
Here \( p \) is assumed to be sufficiently large.

We have a similar result for \( G = SL_2(q) \) with \( q \) square-free (see [4] and [37]). We make the following decomposition of the space \( L^2(SL_2(q)) \). For \( q_1 | q \), define \( E_{q_1} \) as the subspace of functions defined mod \( q_1 \) and orthogonal to all functions defined mod \( q_2 \) for some \( q_2 | q_1, q_2 \neq q_1 \).

\[
L^2(SL_2(q)) = \mathbb{R} \oplus \bigoplus_{q_1 | q} E_{q_1},
\]
which is, in fact, the generalized Fourier-Walsh decomposition corresponding to the product representation
\[
SL_2(q) \approx \prod_{p|q} SL_2(p).
\]
Let \( P_1 \) (respectively \( P_{q_1} \)) be the projection operator on the constant functions (respectively \( E_{q_1} \)).

Lemma 2. Let \( q \) be square free and \( G = SL_2(q) \). For \( \mu \in \mathcal{M}_C(G) \) and \( q_1 | q \) define \( |||\pi_{q_1}(\mu)|||_\infty \) to be the maximum weight of \( |\mu| \) over cosets of subgroups of \( SL_2(q_1) \) that have proper projection in each divisor of \( q_1 \). Given \( \kappa > 0 \), there is \( \kappa' > 0 \) such that if \( \mu \) satisfies for all \( q_1 | q \)
\[
|||\pi_{q_1}(\mu)|||_\infty < q_1^{-\kappa}\|\mu\|_1
\]
then
\[
\|\mu\ast\varphi\|_2 \leq C_q^{-\kappa'}\|\mu\|_1\|\varphi\|_2 \quad \text{for } \varphi \in E_{q_1}.
\]

8. Bounds for congruence transfer operator

Our goal is to obtain a bound for powers of transfer operator \( \|\mathcal{M}_z^n\|_\rho \) for the family of congruence subgroups. Recall that \( \mathcal{M}_z \) acts on functions on \( \Sigma \times G \), so in order to apply Lemma 2 we need to decouple the variables. Returning to (6.2), fix \( m \leq r < n \) such that \( m = n-r \sim \log q \) to be specified. Write
\[
\mathcal{M}_z^n f(x, g) =
\]
where we used the inequality
\[ \sum_{i_1,\ldots,i_n=1} e^{z(\tau(i_1,\ldots,i_n,x)+\tau(i_1,\ldots,x)+\tau(i_1,x))} f((i_n\ldots i_{n-r+1},0); g_{i_n}\ldots g_{i_1}) + O(\lambda_n^m f_\rho \rho^r), \]
where the error term refers to the $L^\infty(G)\langle \Sigma \rangle$-norm.

Fix then the matrices $i_1,\ldots,i_{n-r+1}$ and consider the function $\varphi$ on $G$ defined by
\[ \varphi(g) = f((i_n,\ldots,i_{n-r+1},0), g_{i_n}\ldots g_{i_{n-r+1}}). \]
We assume $f(x,\cdot) \in E_q$ for each $x$; hence $\varphi \in E_q$.

Our aim is to apply Lemma 2 with
\[ \mu = \sum_{i_1,\ldots,i_{n-r}} e^{z(\tau(i_1,\ldots,i_n,x)+\tau(i_1,x))} \delta_{g_{i_1}\ldots g_{i_n-r}}. \]
Thus by (6.3) we have
\[ \|\mu\| \lesssim \lambda_n^m e^{\Re z(\tau(i_n,\ldots,i_{n-r+1},0)+\tau(i_{n-r+1},0))} e^{\frac{\|\rho\|}{m}}, \]
where we used the inequality
\[ |\tau(i_n,\ldots,i_{n-r+1},i_{n-r},\ldots,i_1,x) - \tau(i_n,\ldots,i_{n-r+1},\ldots)| \leq \tau_\rho |\rho|^r. \]

We bound $\|\mu\|_\infty$, which amounts to estimating
\[ \frac{1}{|\Lambda|} \sum_{g_{i_1}\ldots g_{i_n}=g} e^{\Re z(\tau(i_1,\ldots,i_1,x)+\tau(i_1,x))}, \]
where $g$ is fixed. (We use here the fact that the relation $g_{i_m}\ldots g_{i_1} = g \mod q$ is equivalent to $g_{i_m}\ldots g_{i_1} = g$ because of the restriction on $m$). Also because of the index restriction on the transition matrix $A$, the condition $g_{i_m}\ldots g_{i_1} = g$ specifies $(i_m,\ldots,i_1) \in \Sigma$ so that estimating (8.6) amounts to bounding
\[ \frac{1}{|\Lambda|} e^{\Re z(\tau(i_1,\ldots,i_1,x)+\tau(i_1,x))} \sim \lambda^{-m} e^{\Re z(\tau(i_m,\ldots,i_1,x)+\tau(i_1,x))} \]
for fixed $(i_n,\ldots,i_1,x) \in \Sigma$. Thus
\[ \lambda^{-m} |\mathcal{M}^m_{\Re z} \delta_{(i_m,\ldots,i_1)}(x) \leq \lambda^{-m} \|\mathcal{M}^m_{\Re z} \phi\|_\infty \]
with $\phi$ any function on $\Sigma$ satisfying $\phi(i_m,\ldots,i_1,x) = 1$.

By Ruelle’s Theorem (Thm. 1.1),
\[ \|\lambda^{-m} \mathcal{M}^m \phi - (\int \phi d\nu) h\|_{\rho} \lesssim (1-\varepsilon_1)^m \|\phi\|_{\rho}, \]
implying

\[(8.8) \| \lambda^{-m} M^m \phi \|_{\infty} \leq c \left( \int \phi d\nu + (1 - \varepsilon_1)^m \| \phi \|_{\rho} \right). \]

We may now choose \( \phi \) suitably, so as to obtain an estimate

\[(8.9) \lambda^{-m} \| M^m \phi \|_{\infty} \lesssim e^{-cm}. \]

Hence,

\[(8.10) (8.6), (8.7) \lesssim q^{-\kappa}. \]

More generally, we also need to evaluate \( \| \| \pi_{q_1}(\mu) \| \|_{\infty} \) for \( q_1 | q \). It turns out that the issue reduces to the previous one, using the following observation (cf [3]). Let \( H < G \) and \( \pi_p(H) < SL_2(p) \) proper for each \( p | q \). Then we can assume the second commutator of \( \pi_p(H) \) to be trivial if \( p | q_1 \) and hence the second commutator of \( H \) to be trivial (mod \( q_1 \)). Take \( m_1 < m, m_1 \sim \log q_1 \) so as to ensure that words of length 2\( m_1 \) have norm less than \( q_1 \).

Using properties of the free group (see [3]), it follows from the preceding that the number of \( (i_{m_1}, \ldots, i_1) \in \Sigma \) such that \( g_{i_{m_1}} \cdots g_{i_1} \in aH \) is bounded by \( O(m_1 C) \) for some constant \( C \). Hence we may invoke the estimate on (8.7) with \( m \) replaced by \( m_1 \) to obtain also

\[ \| \| \pi_{q_1}(\mu) \| \|_{\infty} < q_1^{-\kappa}. \]

Applying Lemma 2, it follows that

\[ \| \| \pi_{q_1}(\mu) \| \|_{\infty} < q_1^{-\kappa}. \]

Summing (8.11) over \( i_n, \ldots, i_{n-r+1} \) implies by (6.3) again

\[ (8.12) \]

\[ \| \sum_{i_1, \ldots, i_{n-r}} e^{z(\tau(i_n, \ldots, i_{n-r+1,0})+\cdots+\tau(i_1,0))} f(i_n, \ldots, i_{n-r+1}, 0; g_{i_n} \cdots g_{i_1} g) \|_{l^2(G)} \leq q^{-\kappa} \lambda_{q_1}^m e^{Rz(\tau(i_n, \ldots, i_{n-r+1,0})+\cdots+\tau(i_1,0))} e^{\frac{Rz|\tau|_2}{r}} \| f \|_{\infty}. \]

Summing (8.11) over \( i_n, \ldots, i_{n-r+1} \) implies by (6.3) again

\[ (8.12) \]

\[ \| \sum_{i_1, \ldots, i_{n-1}} e^{z(\tau(i_n, \ldots, i_{n-1,0})+\tau(i_{n-1}, i_1,0)+\cdots+\tau(i_1,0))} f((i_n \ldots i_{n-r+1}, 0; g_{i_n} \cdots g_{i_1} g) \|_{l^2(G)} \leq q^{-\kappa} \lambda_{q_1}^m \| f \|_{\infty}. \]
Therefore it follows that if \( n > \log q \)
\[
\| \mathcal{M}_n^a f \|_{L^\infty_{|z|}(\Sigma)} \leq \lambda_{R_2}^n (q^{-\kappa'} \| f \|_\infty + \rho^r |f|_{\rho})
\]
(8.13) \[
\leq \lambda_{R_2}^n q^{-\kappa'} (\| f \|_\infty + \rho^{2\kappa'} |f|_{\rho})
\]
for
(8.14) \[ f \in \mathcal{F}_\rho^t = \mathcal{F}_\rho \cap C_{E_q}(\Sigma). \]

Note that in (8.13) there is no restriction on \( \Im z \).
We also need to estimate \( |\mathcal{M}_z^a f|_{\rho} \).
Let \( x, y \in \Sigma \) be such that \( x_i = y_i \) for \( 0 \leq i < l \). Estimate
\[
|\mathcal{M}_z^a f(x, g) - \mathcal{M}_z^a f(y, g)| \leq
\]
(8.15) \[
\sum_{i_1, \ldots, i_n} e^{Rz}(\tau(i_n, \ldots, i_1, x) + \ldots + \tau(i_1, x)) |f(i_n, \ldots, i_1 x; g_{i_n} \ldots g_{i_1}, g) - f(i_n, \ldots, i_1 y; g_{i_n} \ldots g_{i_1}, g)|
\]
(8.16) \[+ \left| \sum_{i_1, \ldots, i_n} (e^{z(\tau(i_n, \ldots, i_1, x) + \ldots + \tau(i_1, x))) - e^{z(\tau(i_n, \ldots, i_1, y) + \ldots + \tau(i_1, y)))} \right| f(i_n, \ldots, i_1 y; g_{i_n} \ldots g_{i_1}, g)|.
\]

Clearly for the first term we have
(8.17) \[ (8.15) \lesssim \lambda_{R_2}^n |f|_{\rho}^n + l. \]

To estimate (8.16) we repeat the argument leading to (8.13). Thus we bound (8.16) as follows
(8.18) \[
\left| \sum_{i_1, \ldots, i_n} (e^{z(\tau(i_n, \ldots, i_1, x) + \ldots + \tau(i_1, x))) - e^{z(\tau(i_n, \ldots, i_1, y) + \ldots + \tau(i_1, y)))} \right| f(i_n, \ldots, i_{n-r+1}, 0; g_{i_n} \ldots g_{i_1}, g)|
\]
(8.19) \[+ \rho^r |f|_{\rho} \sum_{i_1, \ldots, i_n} \left| (e^{z(\tau(i_n, \ldots, i_1, x) + \ldots + \tau(i_1, x))) - e^{z(\tau(i_n, \ldots, i_1, y) + \ldots + \tau(i_1, y)))} \right|.
\]

Estimate
(8.20) \[
\sum_{i_1, \ldots, i_n} \left| (e^{z(\tau(i_n, \ldots, i_1, x) + \ldots + \tau(i_1, x))) - e^{z(\tau(i_n, \ldots, i_1, y) + \ldots + \tau(i_1, y)))} \right|
\]
\[\leq \sum_{i_1, \ldots, i_n} e^{Rz}(\tau(i_n, \ldots, i_1, x) + \tau(i_1, x)) |1 - e^{z(\tau(i_n, \ldots, i_1, y) + \ldots + \tau(i_1, y) - \tau(i_n, \ldots, i_1) - \ldots - \tau(i_1, x)))}|
\]
\[\lesssim \lambda_{R_2}^n (1 + |\Im z|) |f|_{\rho}^n + \ldots + \rho^l |f|_{\rho}^l \leq \lambda_{R_2}^n \frac{1 + |\Im z|}{1 - \rho} |f|_{\rho}^l; \]
consider the measure

\[ \sum_{i_1, \ldots, i_{n-r}} (e^{z(\pi_n, \ldots, i_1, x) + \cdots + \pi(i_1, x)) - e^{z(\pi_n, \ldots, i_1, y) + \cdots + \pi(i_1, y))}) \delta_{y_{n-r} \cdots y_1} \]

with \( i_1, \ldots, i_{n-r+1} \) fixed.

Repeating (8.20) gives (with \( m = n - r \))

\[ \| \nu \| \lesssim \lambda^m (1 + |3z|) |\tau|_\rho \frac{\rho}{1-\rho} e^{\Re z(\pi_n, \ldots, i_{n-r+1}, 0) + \cdots + \pi(i_1, 0))}. \]

Also, as above, we have

\[ \frac{1}{\| \nu \|_\infty} = \frac{1}{\| \nu \|_\infty} |e^{z(\pi_n, \ldots, i_1, x) + \cdots + \pi(i_1, x)) - e^{z(\pi_n, \ldots, i_1, y) + \cdots + \pi(i_1, y))}| \]

\[ \leq \lambda^{-m} e^{\Re z(\pi_n, \ldots, i_1, x) + \cdots + \pi(i_1, x))} < q^{-\kappa}. \]

and

\[ \frac{1}{\| \nu \|_\infty} \| \pi_{q_1}(\nu) \|_\infty < q_1^{-\kappa} \quad \text{for} \quad q_1 |q|. \]

Therefore, by the results from section 7, we obtain (with \( \varphi \) defined as in section 7) that

\[ \| \nu * \varphi \|_{L^2(G)} \leq q^{-\kappa'} \| \nu \|_\infty \lesssim \lambda^m (1 + |3z|) |\tau|_\rho \frac{\rho}{1-\rho} e^{\Re z(\pi_n, \ldots, i_{n-r+1}, 0) + \cdots + \pi(i_1, 0))} \| f \|_\infty. \]

Summation over \( i_n, \ldots, i_{n-r+1} \) gives then

\[ \| (8.18) \|_{L^2(G)} \lesssim q^{-\kappa'} \lambda^m (1 + |3z|) |\tau|_\rho \| f \|_\infty. \]

From (8.17), (8.21), (8.27), it follows that

\[ \| \mathcal{M}_z^n f(x, \cdot) - \mathcal{M}_y^n f(y, \cdot) \|_{L^2(G)} \lesssim \rho \lambda_{yz}^n \left( \rho^n |f|_\rho + \rho^n (1 + |3z|) |f|_\rho + q^{-\kappa'} (1 + |3z|) \| f \|_\infty \right). \]

Therefore, if \( n > \log q \) we have

\[ \| \mathcal{M}_z^n f \|_\rho \leq C \lambda_{yz}^n q^{-\kappa'} \left( \| f \|_\infty + \rho^{n/2} |f|_\rho \right) (1 + |3z|). \]
Take \( n \) such that
\[
(8.30) \quad n \sim \log q + C \log(1 + |\Im z|)
\]
for a suitable constant \( C \). It follows from (8.13), (8.29) that
\[
(8.31) \quad \| M_z^n f \|_{\infty} + \rho^{\tilde{z}} |M_z^n f|_{\rho} < \lambda_{R_z}^n q^{-\kappa'} (\| f \|_{\infty} + \rho^{\tilde{z}} |f|_{\rho}).
\]
Iterating (8.31) shows that if \( f \in F_{\rho}' \), then for all \( m \in \mathbb{Z}_+ \)
\[
(8.32) \quad \| M_{z}^{mn} f \|_{\infty} + \rho^{\tilde{z}} |M_{z}^{mn} f|_{\rho} \leq \lambda_{R_z}^{mn} q^{-m\kappa'} \| f \|_{\rho},
\]
and hence
\[
(8.33) \quad \| M_{z}^{mn} f \|_{\rho} < \lambda_{R_z}^{mn} q^{-m\kappa'} (1 + |\Im z|) \| f \|_{\rho},
\]
where \( n \) is given by (8.30). Thus for \( m \geq 1 \)
\[
(8.34) \quad \| M_{z}^{m} f \|_{\rho} < \lambda_{R_z}^{m} q^{-m\kappa'} (1 + |\Im z|).
\]
We distinguish two cases: \( \log(1 + |\Im z|) \lesssim \log q \) and \( \log q \ll \log(1 + |\Im z|) \). The conclusion is the following:

**Lemma 3.** Notation being as above, there is \( \varepsilon > 0 \) such that
\[
(8.35) \quad \| M_{z}^{m} f \|_{\rho} < q^{-\varepsilon m} \lambda_{R_z}^{m} \text{ if } |\Im z| \leq q
\]
and
\[
(8.36) \quad \| M_{z}^{m} f \|_{\rho} < |\Im z|^{C} q^{-\varepsilon \frac{\log q}{\log |\Im z|} m} \lambda_{R_z}^{m} \text{ if } |\Im z| > q.
\]

**9. Resolvent of congruence transfer operator**

We now use Lemma 3 to estimate the resolvent \((I - M_z)^{-1}\) on \( F_{\rho}' \). By (6.5), (6.6) this will provide us bounds on \( F(z, x) \), assuming \( \varphi \in E_q \).

Take \( \Re z < -\delta + \varepsilon_1 \) such that
\[
(9.1) \quad \lambda_{-\delta+\varepsilon_1} < e^{\tilde{z}}
\]
with \( \varepsilon > 0 \) from (8.35). If \( |\Im z| < q \), we obtain
\[
(9.2) \quad \|(I - M_z)^{-1} f\|_{\rho} < q^{C} \sum e^{-\varepsilon m} \lambda_{R_z}^{m} \lesssim \frac{1}{\varepsilon} q^{C}.
\]

If \( |\Im z| \geq q \), we impose the restriction
\[
(9.3) \quad \Re z < -\delta + \varepsilon_2 \frac{\log q}{\log |\Im z|}
\]
with \( \varepsilon_2 > 0 \) small enough to ensure that
\[
\lambda_{R_z} e^{-\varepsilon \frac{\log q}{\log |\Im z|}} < e^{-\tilde{z} \frac{\log q}{\log |\Im z|}}.
\]
Under this restriction on \( z \), we obtain from (8.36) that
\[
(9.4) \quad \|(I - M_z)^{-1} f\| \lesssim |\Im z|^{C}.
\]
In summary, we proved the following

**Theorem 9.1.** The resolvent \((I - \mathcal{M}_z)^{-1}\)|_{F_\rho} is holomorphic on the complex region \(D(q)\) given by

\[
\Re z < -\delta + \varepsilon_2 \min \left(1, \frac{\log q}{\log(|\Im z| + 1)}\right)
\]

(with \(\varepsilon_2\) independent of \(q\)) and satisfies the estimate

\[
\|(I - \mathcal{M}_z)^{-1}\)|_{F_\rho} < (q + |\Im z|)^C.
\]

Returning to \((6.5)\), \((6.6)\), it follows that for \(\varphi \in E_q\) the Laplace transform \(F(z, x)\) of \(N(a, x)\) is bounded by

\[
|F(z, x)| \lesssim (q + |\Im z|)^C \frac{\|\varphi\|}{|z|}
\]

for \(z\) satisfying \((9.5)\).

To extract information about \(N(a)\) we apply Fourier inversion to \((5.7)\), following the argument in [16, p. 31] (but with a different class of functions \(k\)).

Specify some smooth and compactly supported bump function \(k\) on \(\mathbb{R}\). We get from \((5.7)\)

\[
\int_{-\infty}^{\infty} k(t) e^{-\delta t} N(a + t) dt = e^{\delta a} \int e^{-ia\theta} \hat{k}(-i\theta) F(-\delta + i\theta) d\theta,
\]

where \(\hat{k}(z) = \int e^{zt} k(t) dt\) is an entire function.

Note that \(|\hat{k}(i\theta)|\) is rapidly decaying since \(k\) is smooth.

In fact, proceeding more precisely, fix a small parameter \(\gamma > 0\) (the localization of \(k\)) and consider functions

\[
k_\gamma(t) = \frac{1}{\gamma} K \left(\frac{t}{\gamma}\right),
\]

where \(K\) is a fixed smooth bump function such that

\[
\int K = 1,
\]

\[
\text{supp} K \subset [-\frac{1}{2}, \frac{1}{2}],
\]

\[
|\hat{K}(\lambda)| \lesssim e^{-|\lambda|^{\frac{1}{2}}} \text{ for } |\lambda| \to \infty.
\]
Hence
\[(9.13) \quad |\hat{k}(z)| \lesssim e^{-|\Im z|^\frac{1}{2}} \quad \text{for} \quad |\Re z| < O(1).\]

Returning to (9.8), modify the line of integration \(\Re z = 0\) to the curve
\[z(\theta) = w(\theta) + i\theta,\]
where
\[(9.14) \quad w(\tau) = \frac{1}{2} \varepsilon_2 \min\left(1, \frac{\log q}{\log(1 + |\theta|)}\right),\]
so as to remain in the analyticity region given by Theorem 9.1.

We obtain
\[e^{\delta a} \int_{-\infty}^{\infty} e^{-aw(\theta)} \hat{k}(z(\theta)) F(-\delta + z(\theta)) d\theta = e^{\delta a} \int_{-\infty}^{\infty} e^{-aw(\theta) - i\theta} \hat{k}(w(\theta) + i\theta) F(-\delta + w(\theta) + i\theta) d\theta,\]
which is bounded by
\[(9.15) \quad \|\varphi\|_2 e^{\delta a} \int_{-\infty}^{\infty} e^{-aw(\theta)} e^{-(|\gamma|/2)\frac{q}{2} + |\theta|\gamma} d\theta,\]
applying (9.13) and (9.7).

From the definition of \(w(\theta)\) it is clear that
\[(9.16) \quad (9.8), (9.15) < e^{\delta a} q^C \gamma^{-C} \exp \left(-a \varepsilon_3 \min\left(1, \frac{\log q}{\log \frac{\gamma}{2}}\right)\right) \|\varphi\|_2.\]

This proves (replacing \(k(t)\) by \(e^{\delta t} k(t)\))

**Proposition 1.** Let \(\varphi \in E_q\) and \(N(a)\) given by (6.7). Then
\[(9.17) \quad \left|\int_{-\gamma/2}^{\gamma/2} k_{\gamma}(t) N(a + t) dt\right| < q^C \gamma^{-C} \exp \left(-a \varepsilon_3 \min\left(1, \frac{\log q}{\log \frac{\gamma}{2}}\right)\right) e^{\delta a} \|\varphi\|_2.\]

10. **Bound for the error term**

Next consider the case where in (5.4), \(\phi = 1\) (the constant function).

Here we consider simply the action of \(\mathcal{L}_z\) on \(\mathcal{F}_\rho(\Sigma)\) exactly as in [16],
but we use the stronger estimates on \((I - \mathcal{L}_z)^{-1}\) following from (5.11),
given by [21].

If \(\Re z < -\delta + \varepsilon_4\) (with \(\varepsilon_4\) small enough) and \(z \notin U\) (some complex neighborhood of \(-\delta\)), (5.11) implies that
\[(10.1) \quad \|(I - \mathcal{L}_z)^{-1}\| \lesssim |\Im z|^2.\]

For \(s \in U\), apply (5.12). Thus
\[\mathcal{L}_z^n = \lambda_z^n (\nu_z \otimes h_z) + (\mathcal{L}_z^n)^n,\]
where\( \| (L^n_z)^n \| < e^{\varepsilon n} \) by (5.13).

Hence for \( z \in U \)

\[
(I - L_z)^{-1} = \frac{1}{1 - \lambda_z} (\nu_z \otimes h_z) + (I - L''_z)^{-1}
\]

with \((I - L''_z)^{-1}\) holomorphic (this is Proposition 7.2 in [16]).

Combining (10.1), (10.2) we get

\[\textbf{Proposition 2.} \]

Consider \( L_z \) acting on \( F^\rho(\Sigma) \). Then for \( \Re z < -\delta + \varepsilon \)

\[
(I - L_z)^{-1} - \frac{1}{1 - \lambda_z} (\nu_z \otimes h_z)
\]

is holomorphic and bounded by \( C( |\Im z|^2 + 1) \).

Let \( \mu_z = \nu_z \otimes h_z \). The function \( \frac{1}{1 - \lambda_z} \) has a pole at \( z = -\delta \) with residue

\[
- \frac{1}{(\frac{d}{dz} \lambda_z)|_{z=-\delta}} = \frac{1}{\int \tau d\mu_{-\delta}}.
\]

Consequently

\[
(I - L_z)^{-1} - \frac{\nu_{-\delta} \otimes h_{-\delta}}{\int \tau d\mu_{-\delta}} \frac{1}{z + \delta}
\]

is analytic for \( \Re z < -\delta + \varepsilon \).

Letting

\[
N(a) = \sum_{y \in \Lambda \atop d_H(0,yw) - d_H(0,w) \leq a} 1
\]

and

\[
F(z) = \int e^{az} N(a) da,
\]

it follows from (5.9) , (10.4) that

\[
F(z) = \frac{1}{z} (I - L_z)^{-1} = \frac{h_{-\delta}(\xi \equiv w)}{\int \tau d\mu_{-\delta}} \frac{1}{z + \delta} + G(z),
\]

where \( G(z) \) is analytic on \( \Re z < -\delta + \varepsilon \) and bounded by \( C( |\Im z|^2 + 1) \).

As in section 9 we have

\[
\int k_\gamma(t)e^{-\delta t} N(a + t) dt = e^{\delta a} \int \hat{k}_\gamma(i\theta) F(-\delta + i\theta)e^{-ia\theta} d\theta
\]

\[
e^{\delta a} \left( C_0 \int_{PV} e^{-ia\theta} \hat{k}_\gamma(i\theta) \frac{1}{i\theta} d\theta + \int e^{-ia\theta} \hat{k}_\gamma(i\theta) G(-\delta + i\theta) \right),
\]

where

\[
C_0 = \frac{h_{-\delta}(\xi \equiv w)}{\int \tau d\nu_{-\delta}}.
\]
The second term in (10.8) is estimated by moving the line of integration $\Re z = 0$ to $\Re z = \frac{1}{2}\varepsilon_5$. We obtain by (9.13) and the assumption on $G$:

(10.10)
$$\left| \int e^{-ia\theta} \tilde{k}_\gamma(i\theta)G(-\delta + i\theta) \right| \lesssim e^{-\frac{\varepsilon_5 a}{4}} \int (1 + \theta^2)e^{-(\gamma|\theta|)^{\frac{1}{2}}}d\theta < c\gamma^{-3}e^{-\frac{\varepsilon_5 a}{4}}.$$ 

Also
$$\int_{PV} e^{-ia\theta} \tilde{k}_\gamma(i\theta) \frac{1}{i\theta}d\theta = \int_0^\infty k_\gamma(t+a)dt \overset{(9.10)}{=} 1.$$ 

Therefore we obtain

Proposition 3. Let $N(a)$ be given by (10.5). Then

(10.11)
$$\int k_\gamma(t)N(a+t)dt = C_0 e^{\delta a} + o\left(\gamma^{-3}e^{(\delta - \varepsilon_6)a}\right)$$

for some $\varepsilon_6 > 0$. Here $C_0$ is a fixed constant.

11. Proof of Theorem 1.4

Let $\varphi$ be a function on $SL_2(q)$ and let $N(a,x)$ denote the counting function given as above by

$$N(a,x) = \sum_{y \in \Lambda, d_H(0, yxw) - d_H(0,xw) \leq a} \varphi(\pi_q(y)).$$

What we proved in Theorem 9.1 is that for $\varphi \in E_q$ the Laplace transform of $N(a,x)$ in $a$ (given by (5.7)) is holomorphic on $D(q)$ given by

(11.1)
$$D(q) = \left\{ z : \Re z < -\delta + \varepsilon_2 \min\left(1, \frac{\log q}{\log(|3z| + 1)} \right) \right\}$$

with $\varepsilon_2$ independent of $q$. Let us denote by $L_z(q)$ the dynamical transfer operator on the congruence subgroup $\Lambda(q)$. Thus $\det(1 - L_z(q))$ is the dynamical (Ruelle’s) zeta-function associated with the congruence subgroup $\Lambda(q)$. Using (5.9) we have that the Laplace transform of $N(a,x)$ is also obtained as the inverse of $(1 - L_z(q))$. Now considering the action of $L_z(q)$ on $\mathcal{F}_\rho(\Sigma(q))$, recalling the decomposition of $L^2(SL_2(q))$ given by (7.15), and applying theorem 9.1 to $E_{q_1}$ for all $q_1|q$, and Proposition 2 to the constant function, we obtain that $1 - L_z(q)$ has holomorphic inverse (apart from $z = -\delta$) on

$$D = D(1) \cap \bigcap_{q_1|q} D(q_1),$$

where

$$D(1) = \{ z : \Re z < -\delta + \varepsilon_5 \}.$$
by Proposition 2. Consequently $D$ is given by

$$D = \left\{ z : \Re z < -\delta + \varepsilon_6 \min \left( 1, \frac{1}{\log(|\Im z| + 1)} \right) \right\}$$

for some $\varepsilon_6$ independent of $q$, implying that dynamical zeta function $\det(1 - L_z(q))$ has no zeros on $D$ (apart from simple zero at $-\delta$).

Theorem 1.4 now follows from the equality of the dynamical zeta-function and Selberg zeta function (Theorem 15.8 in [2]), and the correspondence between the zeros of Selberg’s zeta function and resonances (see [20] and Chapter 10 in [2]).

12. Proof of Theorem 1.5

Propositions 2 and 3 are our basic estimates used in the proof of Theorem 1.5. Note that what comes out Proposition 1 will only play the role of error terms.

Fix a modulus $q$, $(q, q_0) = 1$ (with $q_0$ given by the strong approximation property) and $q$ square-free.

For some element $\xi \in \text{SL}_2(q)$ we need to evaluate

$$N(a; q, \xi) = \left| \{ y \in \Lambda; \pi_q(y) = \xi \text{ and } d_H(0, yw) \leq a \} \right|$$

(replace $a$ by $a + d_H(0, w)$ in (6.7)).

Recall the decomposition of the space $L^2(\text{SL}_2(q))$ in (7.15). Writing

$$1_{g=\xi} = \frac{1}{|\text{SL}_2(q)|} + \sum_{q_1|q, q_1 \neq 1} P_{q_1}(1_{g=\xi}),$$

we get

$$N(a; q, \xi) = \frac{1}{|\text{SL}_2(q)|} \sum_{y \in \Lambda} 1$$

$$+ \sum_{q_1|q} \sum_{y \in \Lambda} \varphi_{q_1}(\pi_{q_1}(y))$$

with

$$\varphi_{q_1} = P_{q_1}(1_{g=\xi}) \in E_{q_1}.$$ 

Thus

$$\|\varphi_{q_1}\|_2 < \frac{|\text{SL}_2(q_1)|^{1/2}}{|\text{SL}_2(q)|^{1/2}}.$$
We use Proposition 3 to evaluate the right-hand side of (12.3) and Proposition 1 to bound terms (12.4). Hence, fixing some $\gamma > 0$

$$\int k_\gamma(t) N(a+t; q, \xi) \, dt = \frac{C_1}{|\text{SL}_2(q)|} e^{\delta a} + o(\gamma^{-3} e^{-ca} e^{\delta a})$$

$$+ \gamma^{-C} \sum_{q_1 \mid q, q_1 \neq 1} q_1^C \exp \left( -ca \min \left( 1, \frac{\log q_1}{\log \frac{a}{\gamma}} \right) \right) \frac{|\text{SL}_2(q_1)|^{\frac{1}{2}}}{|\text{SL}_2(q)|} e^{\delta a}. \quad (12.6)$$

We estimate (12.7) as

$$\frac{\gamma^{-C} |a|^C}{|\text{SL}_2(q)|} \left( \sum_{q_1 \mid q, \ 1 < q_1 < \frac{|a|}{\gamma}} e^{-ca \log \frac{q_1}{\log \frac{a}{\gamma}}} \right) e^{\delta a}$$

$$+ \gamma^{-C} q_1^C e^{(\delta-c)a} \quad (12.8)$$

and

$$\sum_{q_1 \mid q, q_1 \neq 1} e^{-ca \log \frac{q_1}{\log \frac{a}{\gamma}}} < \prod_{p \mid q} \left( 1 + e^{-ca \log \frac{a}{\log \frac{a}{\gamma}}} \right) - 1$$

$$< \exp \left( \sum_{s=2}^{\infty} e^{-ca \log \frac{s}{\log \frac{a}{\gamma}}} \right) - 1 < e^{-c \log \frac{a}{\log \frac{a}{\gamma}}}, \quad (12.9)$$

assuming

$$\log \frac{1}{\gamma} \ll a. \quad (12.10)$$

Therefore we proved the following result, of which Theorem 1.5 is an immediate consequence.

**Proposition 4.** Notation being as above, we have

$$\int k_\gamma(t) N(a+t; q, \xi) \, dt = \frac{e^{\delta a}}{|\text{SL}_2(q)|} \left( C_1 + o(\gamma^{-C} e^{-ca} e^{\delta a}) \right) + \gamma^{-C} q_1^C e^{(\delta-c)a}, \quad (12.11)$$

where we assume

$$\log \frac{1}{\gamma} \ll \frac{a}{\log a}. \quad (12.12)$$

We remark that what is really required for sieving applications is a bound for the ratio

$$\frac{\int k_\gamma(t) N(a+t; q) \, dt}{\int k_\gamma(t) N(a+t) \, dt} \quad (12.13)$$
of the form
\[ \frac{1}{|SL_2(q)|} + O(e^{-\varepsilon a}q^C) \]
or
\[ \frac{1}{|SL_2(q)|} \left( 1 + O(e^{-c \log a}) \right) + O(e^{-\varepsilon a}q^C). \]

To bound the ratio (12.14) it suffices to use Proposition 1 (which builds crucially on the generalized expansion result given by Lemma 2) combined with the result of Lalley [16]. Of course, the results of Dolgopyat [8] and Naud [21], [22] are necessary to establish Theorem 1.4, which is of independent interest.

13. Proof of Theorem 1.6

13.1. Combinatorial sieve. As in [4], we will make use of the simplest combinatorial sieve which is turn is based on the Fundamental Lemma in the theory of elementary sieve, see [14] and [13]. Our formulation is tailored for the applications below.

Let \( A \) denote a finite sequence \( a_n, n \geq 1 \) of nonnegative numbers. Denote by \( X \) the sum
\[ \sum_n a_n = X. \]

\( X \) will be large, in fact tending to infinity. For a fixed finite set of primes \( B \) let \( z \) be a large parameter (in our applications \( z \) will be a small power of \( X \) and \( B \) will usually be empty). Let
\[ P = P_z = \prod_{p \leq z, p \notin B} p. \]

Under suitable assumptions about sums of \( A \) over \( n \)'s in progressions with moderate-size moduli \( d \), the sieve gives upper and lower estimates which are of the same order of magnitude for sums of \( A \) over the \( n \)'s which remain after sifting out numbers with prime factors in \( P \).

More precisely, let
\[ S(A, P) := \sum_{(n,P)=1} a_n. \]

The assumptions on sums in progressions are as follows:

\( (A_0) \) For \( d \) square-free, and having no prime factors in \( B \) \((d < X)\), we assume that the sums over multiples of \( d \) take the form
\[ \sum_{n \equiv 0(d)} a_n = \beta(d)X + r(A, d), \]
where $\beta(d)$ is a multiplicative function of $d$ and

$$\text{for } p \not\in B, \beta(d) \leq 1 - \frac{1}{c_1} \text{ for a fixed } c_1.$$  

The understanding being that $\beta(d)X$ is the main term and that the remainder $r(A, d)$ is smaller, at least on average (see the next axiom).

$(A_1)$ $A$ has level distribution $D = D(X)$, $(D < X)$ that is

$$\sum_{d \leq D} |r(d, A)| \ll \frac{X}{(\log X)^B} \text{ for all } B > 0.$$  

$(A_2)$ $A$ has sieve dimension $t > 0$, that is for a fixed $c_2$ we have

$$\left| \sum_{\substack{w \leq p \leq z \atop p \not\in B}} \beta(p) \log p - t \log \frac{z}{w} \right| \leq c_2$$

for $2 \leq w \leq z$.

In terms of these conditions $(A_0)$, $(A_1)$, $(A_2)$ the elementary combinatorial sieve yields:

**Theorem 13.1.** Assume $(A_0)$, $(A_1)$ and $(A_2)$ for $s > 9t$ and $z = D^{1/s}$ and $X$ large we have

$$(13.5) \quad \frac{X}{(\log X)^t} \ll S(A, P_z) \ll \frac{X}{(\log X)^t}. $$

13.2. **Applying the sieve.** Now let $\Lambda$ be a Zariski dense subgroup of $SL(2, \mathbb{Z})$ and let $f \in \mathbb{Z}[x_{ij}]$ be weakly primitive with $t(f)$ irreducible factors. The key nonnegative sequence $a_n$ to which we apply the combinatorial sieve is defined as follows: for $n \geq 0$ we let

$$(13.6) \quad a_n = a_n(T) = \sum_{\substack{\gamma \in \Lambda \atop |\gamma| \leq T \atop |f(\gamma)| = n}} 1.$$  

The sums on progressions are then, for $d \geq 1$ square free

$$(13.7) \quad \sum_{n \equiv 0(d)} a_n(T) = \sum_{\substack{\gamma \in \Lambda : |\gamma| \leq T \atop f(\gamma) \equiv 0(d)}} 1 = \sum_{\rho \in \Lambda / \Lambda(d)} \sum_{\substack{\gamma \in \Lambda(d) \atop f(\rho) \equiv 0(d) \atop |\gamma| \leq T}} 1.$$
Consider the case of $\delta < 1/2$; the case of $\delta > 1/2$ is similar and simpler. According to Theorem 1.5 we then obtain

(13.8) \[
\sum_{n \equiv 0(d)} a_n(T) = \sum_{\rho \in \Lambda / \Lambda(d), f(\rho) \equiv 0(d)} \frac{T^{2\delta}}{|\Lambda_d|} \left(1 + O\left(T^{-\frac{1}{\log \log T}}\right)\right) + O\left(d^C T^{2\delta - \epsilon_1}\right),
\]

\[
= X \frac{|\Lambda_d^f|}{|\Lambda_d|} + O\left(\frac{|\Lambda_d^f|}{|\Lambda_d|} X^{1 - \frac{1}{25 \log \log X}}\right) + O\left(|\Lambda_d^f| d^C X^{1 - \frac{\epsilon_1}{25}}\right).
\]

where

(13.9) \[
X = \sum_{k \in \mathbb{N}} a_k(T) = \sum_{\gamma \in \Lambda \atop |\gamma| \leq T} 1,
\]

$\Lambda_d$ is the reduction of $\Lambda$ mod $d$, and $\Lambda_d^f$ is the subset of $\Lambda_d$ at which $f(x) = 0 \text{ mod } d$.

Using strong approximation theorem [19] and Goursat lemma as in [4] we obtain that outside of finite set of primes $S(\Lambda)$ we have $\Lambda_p \cong \text{SL}_2(\mathbb{F}_p)$ and $\Lambda \rightarrow \Lambda_{d_1} \times \Lambda_{d_2}$ is surjective for $(d_1, d_2) = 1$ and $d_1 d_2$ square free. Let

(13.10) \[
\beta(d) = \frac{|\Lambda_d^f|}{|\Lambda_d|}.
\]

Using Lang-Weil theorem [18] as in [4], we obtain

(13.11) \[
|\Lambda_d^f| \ll d^2
\]

and

(13.12) \[
\frac{|\Lambda_d^f|}{|\Lambda_d|} = \frac{t(f)}{p} + O(p^{-\frac{3}{2}}).
\]

Hence we have

(13.13) \[
\sum_{n \equiv 0(d)} a_n(T) = \beta(d) X + r(A, d),
\]

with

(13.14) \[
r(A, d) \ll \frac{1}{d} X^{1 - \frac{1}{25 \log \log X}} + d^{C+2} X^{1 - \frac{\epsilon_1}{25}}.
\]

Verification of $(A_0)$ is completely analogous to Proposition 3.1 in [4].

Regarding the level distribution $(A_1)$ we have that

(13.15) \[
\sum_{d \leq D} |r(A, d)| \ll X^{1 - \frac{1}{25 \log \log X}} + D^{C+3} X^{1 - \frac{\epsilon_1}{25}} \ll \frac{X}{(\log X)^B}
\]
for any $B > 0$ as long as

$$D \leq X^\tau \text{ with } \tau < \frac{2\delta}{(C + 3)\varepsilon_1}. \quad (13.16)$$

Finally, to verify the third axiom concerning the sieve dimension, we have, using (13.12), that

$$\sum_{w \leq p \leq z} \beta(p) \log p = \sum_{w \leq p \leq z} \left( \frac{t \log p}{p} + O \left( \frac{\log p}{p^{3/2}} \right) \right) = t \log \frac{z}{w} + O(1), \quad (13.17)$$

which establishes $(A_2)$ with the sieve dimension being $t$.
