Abstract
In this paper we show that for an almost finite minimal ample groupoid $G$, its reduced $C^*$-algebra $C^*_r(G)$ has real rank zero and strict comparison even though $C^*_r(G)$ may not be nuclear in general. Moreover, if we further assume $G$ being also second countable and non-elementary, then its Cuntz semigroup $\text{Cu}(C^*_r(G))$ is almost divisible and $\text{Cu}(C^*_r(G))$ and $\text{Cu}(C^*_r(G) \otimes \mathcal{Z})$ are canonically order-isomorphic, where $\mathcal{Z}$ denotes the Jiang-Su algebra.

1 Introduction

Almost finiteness for an ample groupoid was introduced by Matui in [20]. He studied their topological full groups as well as the applications of almost finiteness to the homology of étale groupoids (see [21] for a survey of results in this direction). In [12], David Kerr specialised to almost finite group actions and treated them as a topological analogue of probability measure preserving hyperfinite equivalence relations, with the ultimate goal of transferring ideas from the classification of equivalence relations and von Neumann algebras to the world of (amenable) topological dynamics and $C^*$-algebras.

Recently, the classification program for $C^*$-algebras has culminated in the outstanding theorem that all separable, simple, unital, nuclear, $\mathcal{Z}$-stable $C^*$-algebras satisfying the universal coefficient theorem UCT are classified by their Elliott-invariant (see [30, Corollary D] and [8, Corollary D]). Recall that a $C^*$-algebra is $\mathcal{Z}$-stable if $A \otimes \mathcal{Z} \cong A$, where $\mathcal{Z}$ denotes the so-called Jiang-Su algebra. By the Toms-Winter conjecture $\mathcal{Z}$-stability is conjecturally equivalent to strict comparison (or equivalently, almost unperforation of the Cuntz semigroup) for separable, simple, nuclear, non-elementary $C^*$-algebras. It is known that $\mathcal{Z}$-stability implies strict comparison in general and the converse is indeed the last remaining open step in the Toms-Winter conjecture (see [33] for an overview and [7] for the state of the art for the conjecture).

Going back to topological dynamics, David Kerr’s approach in [12] has seen dramatic success. He was able to show that a crossed product $C(X) \rtimes \Gamma$ associated to a free and minimal action of an (amenable) infinite group $\Gamma$ is $\mathcal{Z}$-stable provided that the action is almost finite (see [12, Theorem 12.4]). Combining this with the recent result in [13, Theorem 8.1], which states that every free action of a countably infinite (amenable) group with subexponential growth on a compact metrizable space with finite covering dimension is almost finite, we get a huge supply of classifiable $C^*$-algebras arising from topological dynamics (see [13, Theorem 8.2]). On the other hand, important results by Kumjian [16] and Renault [25] show that (twisted) étale groupoids play a role in $C^*$-algebras similar to the role of probability measure preserving equivalence relations play in the theory of von Neumann algebras. Moreover, Xin Li proved in [18] that every separable, simple, unital, nuclear, $\mathcal{Z}$-stable $C^*$-algebra satisfying the UCT has a twisted étale groupoid model. Consequently, we are led to study $\mathcal{Z}$-stability and strict comparison of groupoid $C^*$-algebras.

In this article we take a step in this direction by considering the case of étale groupoids with a zero-dimensional compact unit space. Indeed, we take a slightly different route than Kerr and verify the last condition in the Toms-Winter conjecture for $C^*$-algebras arising from almost finite groupoids:

**Theorem 1.1** Let $G$ be an almost finite minimal ample groupoid with compact unit space. Then its reduced groupoid $C^*$-algebra $C^*_r(G)$ has strict comparison and real rank zero. In particular, the Cuntz semigroup $\text{Cu}(C^*_r(G))$ is almost unperforated.
If we furthermore assume that $G$ is second-countable and non-elementary\(^1\), then $\text{Cu}(C^*_r(G))$ is almost divisible and $\text{Cu}(C^*_r(G)) \cong \text{Cu}(C^*_r(G) \otimes \mathcal{Z})$ order-isomorphic via the first factor embedding.

The class of groupoids (and their C*-algebras) under study in Theorem 1.1 may have bizarre properties. Indeed, part of the novelty of this result is that it holds even for non-separable and non-nuclear C*-algebras. For instance, Gabor Elek constructed in [9, Theorem 6] a non-amenable minimal almost finite ample groupoid $G$ so that $C^*_r(G)$ is not nuclear. In addition, we show in Remark 3.1 that the C*-algebra $C^*_r(G)$ of an almost finite ample groupoid may not even be exact.

In [28] Suzuki develops a new strategy which in essence is a local version of Phillips’ large subgroupoid technique [22]. Using this method, he is able to verify that almost finite minimal groupoid C*-algebras have stable rank 1. Moreover, in [28, Remark 4.3] he claims that a suitably adapted strategy indeed also yields real rank zero and strict comparison for such groupoid C*-algebras. In this note we carry out all the necessary intermediate steps (some of which might be of independent interest) in detail, as we believe concrete proofs of these facts would be a useful contribution to the literature.

As mentioned before, Toms-Winter conjecture predicts that $C^*_r(G)$ in the above theorem should be $\mathcal{Z}$-stable, provided that $G$ is also assumed to be amenable. Combining Theorem 1.1 and Proposition 3.1 with the main theorems in [6, 15, 27, 31], we obtain the following:

**Corollary 1.1** Let $G$ be an amenable minimal second-countable non-elementary almost finite ample groupoid with compact unit space. Let $M(G)$ be the compact convex set of invariant positive regular Borel probability measures on $G(0)$.

*If the extremal boundary of $M(G)$ is compact and finite-dimensional in the weak*\(^*\)-topology, then $C^*_r(G)$ is a separable simple unital nuclear $\mathcal{Z}$-stable C*-algebra.*

**Remark 1.1** In a very recent article Castillejos, Evington, Tikuisis and White proved that the Toms-Winter conjecture holds among separable simple nuclear, non-elementary $C^*$-algebras which have uniform property $\Gamma$ (see [7, Definition 2.1 and Theorem A]). This provides an alternative way of obtaining Corollary 1.1. Indeed, if $G$ is an amenable, minimal, second-countable, non-elementary, étale groupoid with compact unit space such that the extremal boundary of $M(G)$ is compact and finite-dimensional in the weak*\(^*\)-topology, then the reduced groupoid C*-algebra $C^*_r(G)$ has uniform property $\Gamma$ by [7, Proposition 5.7] provided $G$ is either principal (see [19, Lemma 4.3]) or almost finite (see Proposition 3.1).

Throughout the paper, all groupoids are assumed to be locally compact, Hausdorff, and their unit spaces are assumed to be compact and totally disconnected.

---

\(^1\) That is to say $G \not\cong \mathcal{R}_n$ for any $n \in \mathbb{N}$, where $\mathcal{R}_n$ is the discrete full equivalence relation on $\{1, \ldots, n\}$. 

Birkhäuser
2 Preliminaries

In this first section, we will recall some background about both $C^*$-algebras and groupoids. We encourage the reader to look at [2] for further details about these topics.

2.1 The Cuntz semigroup and Murray–von Neumann semigroup

Let $A$ be a $C^*$-algebra and let $\mathcal{K}$ denote the algebra of compact operators on a separable infinite-dimensional Hilbert space. Let $(A \otimes \mathcal{K})_+$ denote the set of positive elements in $A \otimes \mathcal{K}$. Given $a, b \in (A \otimes \mathcal{K})_+$, we say that $a$ is Cuntz subequivalent to $b$ (in symbols $a \prec b$), if there is a sequence $(v_n)$ in $A \otimes \mathcal{K}$ such that $a = \lim_n v_n b v_n^*$. We say that $a$ and $b$ are Cuntz equivalent (in symbols $a \sim b$), if both $a \prec b$ and $b \prec a$. The relation $\prec$ is clearly transitive and reflexive and $\sim$ is an equivalence relation on $(A \otimes \mathcal{K})_+$.

We define the Cuntz semigroup of a $C^*$-algebra $A$ to be $\text{Cu}(A) = (A \otimes \mathcal{K})_+/\sim$, and the equivalence class of $a \in (A \otimes \mathcal{K})_+$ in $\text{Cu}(A)$ is denoted by $\langle a \rangle$. In particular, $\text{Cu}(A)$ is a partially ordered abelian semigroup equipped with order and addition as:

$$\langle a \rangle \leq \langle b \rangle \iff a \prec b, \quad \langle a \rangle + \langle b \rangle = \langle a \oplus b \rangle,$$

using a suitable isomorphism between $M_2(\mathcal{K})$ and $\mathcal{K}$.

Similarly, the Murray–von Neumann semigroup $V(A)$ of a $C^*$-algebra $A$ is defined as the set of Murray–von Neumann equivalence classes of projections in $(A \otimes \mathcal{K})$. Recall that for $p$ and $q$ projections in $(A \otimes \mathcal{K})$, we say that $p$ and $q$ are Murray–von Neumann equivalent if there exists $v \in (A \otimes \mathcal{K})$ with $p = vv^*$ and $q = v^* v$. The class of a projection $p \in (A \otimes \mathcal{K})$ in $V(A)$ is denoted by $[p]$. We also say that $p$ is Murray–von Neumann subequivalent to $q$ if $p$ is Murray–von Neumann equivalent to a subprojection of $q$. It is worth mentioning that when $A$ is a stably finite $C^*$-algebra, the natural map $V(A) \to Cu(A)$ given by $[p] \mapsto \langle p \rangle$ is an injective order-embedding. In this article we are only concerned with stably finite $C^*$-algebras. Hence, we will use this order-embedding without further mention. We encourage the readers to look at [3] for further details.

2.2 Strict comparison

Let $T(A)$ be the tracial state space of a $C^*$-algebra $A$. Given $\tau \in T(A)$, there is a canonical extension of $\tau$ to a trace $\tau_\infty : (A \otimes \mathcal{K})_+ \to [0, \infty]$. Abusing notation, we usually denote $\tau_\infty$ by $\tau$. The induced lower semicontinuous dimension function $d_\tau : (A \otimes \mathcal{K})_+ \to [0, \infty]$ is given by

$$d_\tau(a) := \lim_n \tau(a^{1/n}),$$

for $a \in (A \otimes \mathcal{K})_+$. 
If \(a, b \in (A \otimes K)_+\) satisfy \(a \preceq b\), then \(d_\tau(a) \leq d_\tau(b)\). Therefore, \(d_\tau\) induces a well-defined, order-preserving map \(\text{Cu}(A) \to [0, \infty]\), which we also denote by \(d_\tau\).

**Definition 2.1** Let \(A\) be a unital simple \(C^*\)-algebra. We say that \(A\) has **strict comparison** (with respect to tracial states) if for all \(a, b \in (A \otimes K)_+\) we have \(a \preceq b\) whenever \(d_\tau(a) < d_\tau(b)\) for all \(\tau \in T(A)\).

If a unital simple \(C^*\)-algebra \(A\) has strict comparison (with respect to tracial states), then its Cuntz semigroup \(\text{Cu}(A)\) is **almost unperforated** in the sense that whenever \(\langle a \rangle, \langle b \rangle \in \text{Cu}(A)\) satisfy \((k + 1)\langle a \rangle \leq k\langle b \rangle\) for some \(k \in \mathbb{N}\), it follows that \(\langle a \rangle \leq \langle b \rangle\). If \(A\) is an exact \(C^*\)-algebra, then every finite-valued 2-quasitrace on \(A\) is a trace (see [11]). Hence, the converse implication holds for all unital simple exact \(C^*\)-algebras (see [29, Remark 9.2. (3)]).

### 2.3 Groupoids

Given a groupoid \(G\) we usually denote its unit space by \(G^{(0)}\) and write \(r, s : G \to G^{(0)}\) for the range and source maps, respectively. In this paper, we will only consider groupoids equipped with a locally compact, Hausdorff topology making all the structure maps continuous. A groupoid \(G\) is called **étale** if the range map, regarded as a map \(r : G \to G\), is a local homeomorphism, and it is called **ample** if additionally, the unit space \(G^{(0)}\) is totally disconnected. Moreover, a subset \(V \subseteq G\) is called **bisection** if the restrictions of the source and range maps to \(V\) are homeomorphisms onto their respective images. Recall that every ample groupoid \(G\) admits a basis for its topology consisting of compact and open bisections.

The product of two subsets \(A, B \subseteq G\) in \(G\) is given by

\[
AB = \{ab \in G \mid a \in A, b \in B, s(a) = r(b)\}.
\]

Whenever \(B = \{x\}\) for a single element \(x \in G^{(0)}\), we will omit the braces and just write \(Ax\).

For a subset \(D \subseteq G^{(0)}\), we say that the set \(D\) is **\(G\)-invariant** if for every \(g \in G\) we have \(r(g)D \Leftrightarrow s(g)D\), and we say that \(D\) is **\(G\)-full** if it satisfies that \(r(GD) = G^{(0)}\). Related to that, we say that a groupoid \(G\) is **minimal** if there are no proper non-trivial closed \(G\)-invariant subsets of \(G^{(0)}\). Moreover, a Borel measure \(\mu\) on \(G^{(0)}\) is called invariant if \(\mu(s(V)) = \mu(r(V))\) for every open bisection \(V \subseteq G\); we will denote by \(M(G)\) the compact (in the weak*-topology) convex set of invariant positive regular Borel probability measures on \(G^{(0)}\).

The isotropy groupoid of \(G\) is the subgroupoid \(\text{Iso}(G) = \{g \in G \mid s(g) = r(g)\}\), and we say that \(G\) is **principal** if \(\text{Iso}(G) = G^{(0)}\). We say that \(G\) is **topologically principal** if the set of points of \(G^{(0)}\) with trivial isotropy group is dense in \(G^{(0)}\).

Let us finish this subsection by recalling that the reduced \(C^*\)-algebra associated to an étale groupoid \(G\), denoted by \(C^*_r(G)\), is the completion of \(C_c(G)\) by the norm coming from a single canonical regular representation of \(C_c(G)\) on a Hilbert module over \(C_0(G^{(0)})\) (see [24] for further details).
2.4 Almost finiteness

In this subsection, we recall the definition of almost finiteness and state some known properties for almost finite groupoids.

Definition 2.2 [20, Definition 6.2] Let $G$ be an ample groupoid with compact unit space.

1. We say that $K \subseteq G$ is an elementary subgroupoid if it is a compact open principal subgroupoid of $G$ such that $K^{(0)} = G^{(0)}$.
2. Given a compact subset $C \subseteq G$ and $\varepsilon > 0$, a compact subgroupoid $K \subseteq G$ with $K^{(0)} = G^{(0)}$ is called $(C, \varepsilon)$-invariant, if for all $x \in G^{(0)}$ we have
   \[ \frac{|CKx \setminus Kx|}{|Kx|} < \varepsilon. \]
3. We say that $G$ is almost finite if for every compact set $C \subseteq G$ and every $\varepsilon > 0$, there exists a $(C, \varepsilon)$-invariant elementary subgroupoid $K \subseteq G$.

Throughout the paper, whenever we say that a groupoid $G$ is almost finite, we also assume that $G$ is an ample groupoid with compact unit space.

Definition 2.3 [28, Definition 3.2] Let $K$ be a compact groupoid. A clopen castle for $K$ is a partition into non-empty clopen subsets such that the following conditions hold:

1. For each $1 \leq i \leq n$ and $1 \leq j, k \leq N_i$ there exists a unique compact open bisection $V_{j,k}^{(i)}$ of $K$ such that $s(V_{j,k}^{(i)}) = F_{j,k}^{(i)}$ and $r(V_{j,k}^{(i)}) = F_{j,k}^{(i)}$.
2. The pair $(F_{j,k}^{(i)}, \{V_{j,k}^{(i)} \mid 1 \leq j, k \leq N_i\})$ is called the $i$-th tower of the castle and the sets $F_{j,k}^{(i)}$ are called the levels of the $i$-th tower.

Remark 2.1 Note that the uniqueness of the bisections in (2) above has an important consequence: If $\theta_{j,k}^{(i)} : F_{j,k}^{(i)} \to F_{j,k}^{(i)}$ denotes the partial homeomorphism corresponding to the bisection $V_{j,k}^{(i)}$, i.e. $\theta_{j,k}^{(i)} = r \circ (s_{V_{j,k}^{(i)}})^{-1}$, then we have $(\theta_{j,k}^{(i)})^{-1} = \theta_{j,k}^{(i)}$, $\theta_{j,k}^{(i)} \circ \theta_{j,k}^{(i)} = \theta_{j,k}^{(i)}$, and $\theta_{j,k}^{(i)} = id_{F_{j,k}^{(i)}}$. 

© Birkhäuser
As already mentioned in [28], every compact ample principal groupoid always admits a clopen castle by [20, Lemma 4.7]. It follows that Definition 2.2 is equivalent to the definition of almost finiteness given in [28, Definition 3.6] by Suzuki. Due to this fact, we will be using both equivalent notions of almost finiteness without further notice.

Finally, let us list some facts about almost finite groupoids that will be used in the sequel:

1. If \( G \) is an almost finite groupoid, it follows that \( M(G) \neq \emptyset \) by [28, Lemma 3.9]. In particular, its extreme boundary \( \partial_e M(G) \) is non-empty as well.
2. If \( G \) is almost finite and minimal, then \( G \) is topologically principal by [28, Lemma 3.10].
3. Let \( G \) be an almost finite groupoid and \( A, B \) be compact open subsets of \( G(0) \). If \( \mu(A) < \mu(B) \) for all \( \mu \in M(G) \), then \( A \preceq B \) by [2, Lemma 3.7], where \( A \preceq B \) means \( A \) is dynamically subequivalent to \( B \) in the sense that there exist finitely many compact open bisections \( V_1, \ldots, V_N \) of \( G \) such that \( A = \bigcup_{i=1}^n \kappa(V_i) \) and the sets \( \{r(V_i)\}_{i=1}^n \) are pairwise disjoint subsets of \( B \). In particular, \( 1_A \) is Murray–von Neumann subequivalent to \( 1_B \) in \( C^*_r(G) \), where \( 1_A \) denotes the characteristic function with support \( A \).

3 \( C^* \)-algebras of almost finite groupoids

This section is the main part of the paper. Here we verify two important facts mentioned without proof in [28, Remark 4.3] by Suzuki: \( C^* \)-algebras of minimal almost finite groupoids have real rank zero and strict comparison. These are build upon local versions of results in [22], but there are some subtle differences which we expose below.

Let us begin by identifying the tracial states on \( C^*_r(G) \), which might be of independent interest. It is well-known that for a principal étale groupoid \( G \) the tracial states on \( C^*_r(G) \) are in a one-to-one correspondence with the invariant probability measures on \( G(0) \). Since an almost finite groupoid \( G \) is in some sense locally approximated by principal groupoids, it might not come as a surprise that the one-to-one correspondence persists in this more general setting.

**Lemma 3.1** Let \( G \) be an almost finite groupoid and \( \tau \) be a tracial state on \( C^*_r(G) \). Then

\[
\tau = \tau_{|C(G(0))} \circ E,
\]

where \( E : C^*_r(G) \to C(G(0)) \) is the canonical conditional expectation.

**Proof** For convenience let \( \tau' := \tau_{|C(G(0))} \circ E \). It is enough to show that for every fixed \( f \in C_c(G) \), we have \( |\tau(f^*f) - \tau'(f^*f)| < \varepsilon \) for any \( \varepsilon > 0 \), since the linear span of elements of the form \( f^*f \) is dense in \( C^*_r(G) \). We may assume that \( ||f|| \leq 1 \) as well. As \( supp(f^*f) \) is compact we can find compact open bisections \( V_1, \ldots, V_N \) in \( G \) such that
supp($f^* f$) ⊆ $\bigcup_{i=1}^{N} V_i$. Let $V$ be the (compact and open) union of the $V_i$. Applying almost finiteness of $G$ now, we can find a $(V \cap V^{-1}, \frac{\epsilon}{2N})$-invariant elementary subgroupoid $K$ of $G$. Clearly, $K$ is also $(V_i \cap V_i^{-1}, \frac{\epsilon}{2N})$-invariant for every $1 \leq i \leq N$. The restrictions of $\tau$ and $\tau'$ to the subalgebra $C(G^{(0)})$ define the same $G$-invariant probability measure $\mu \in M(G)$. Since $K$ is compact open in $G$ with $K^{(0)} = G^{(0)}$, we can also view $\mu$ as an element in $M(K)$. By [28, Lemma 3.8] we have $|\mu(r(V_i \setminus K))| < \frac{\epsilon}{2N}$ for every $1 \leq i \leq N$. Hence, we get

$$|\mu(r(V \setminus K))| \leq \sum_{i=1}^{N} |\mu(r(V_i \setminus K))| < \frac{\epsilon}{2}.$$ 

In other words, if $p := \chi_{r(V \setminus K)}$ denotes the characteristic function of $r(V \setminus K)$, then

$$\tau(p) = \tau'(p) < \frac{\epsilon}{2}.$$ 

We can now follow the arguments in [22, Lemma 2.10] to get the result. For the convenience of the reader we reproduce the argument here: First, note that from $((1 - p)f^* f)(g) = (1 - p)(r(g))f^* f(g)$ and the definition of $p$, it follows that $(1 - p)f^* f \in C(K)$. By taking the adjoint, we also get $f^* f(1 - p) \in C(K)$. Since $p \in C(K)$, it follows that $f^* f - pf^* fp = (1 - p)f^* f + pf^* f(1 - p) \in C(K)$. Since $K$ is a principal groupoid, $\tau$ and $\tau'$ coincide on the $C^*$-subalgebra $C_r(K) \subseteq C_r(G)$ (see for example [19, Lemma 4.3]). In particular, we get

$$\tau(f^* f - pf^* fp) = \tau'(f^* f - pf^* fp).$$ 

On the other hand, it follows from $pf^* fp \leq ||f||^2 p \leq p$, that we have $0 \leq \tau(pf^* fp) \leq \tau(p) < \frac{\epsilon}{2}$ and similarly $0 \leq \tau'(pf^* fp) \leq \tau'(p) < \frac{\epsilon}{2}$. Combining these facts we arrive at

$$|\tau(f^* f) - \tau'(f^* f)| = |\tau(pf^* fp) - \tau'(pf^* fp)| < \epsilon,$$

as desired. 

Recall that $M(G)$ denotes the compact (in the weak$^*$-topology) convex set of invariant positive regular Borel probability measures on $G^{(0)}$, and $T(C_r^*(G))$ denotes the tracial state space of $C_r^*(G)$.

**Proposition 3.1** Let $G$ be an almost finite groupoid. Then the canonical map $T(C_r^*(G)) \to M(G)$ is an affine homeomorphism. In particular, we can also identify their extreme boundaries $\partial_e T(C_r^*(G)) = \partial_e M(G)$, which are non-empty.

**Proof** It is well-known that this map is affine, continuous, and surjective. Injectivity now follows from Lemma 3.1. By the affineness we also have that $\partial_e T(C_r^*(G)) = \partial_e M(G)$, which are non-empty as $M(G) \neq \emptyset$. 

\[\square\]
Let us now focus on the proofs of real rank zero and strict comparison. For many of the intermediate steps in the proof, we only need the hypothesis that $G^{(0)}$ admits an invariant measure with full support (i.e., $\mu \in M(G)$ such that $\text{supp}(\mu) = G^{(0)}$). Clearly, every measure in $M(G) \neq \emptyset$ has full support for a minimal almost finite groupoid $G$ (see [20, Lemma 6.8]).

**Lemma 3.2** Let $G$ be an almost finite groupoid such that $G^{(0)}$ admits a full-supported invariant measure. For every finite subset $F \subseteq C_c(G)$ and every $\varepsilon > 0$, there exists an elementary subgroupoid $K \subseteq G$ and a compact open subset $W \subseteq G^{(0)}$ such that if $p := \chi_W$ is the characteristic function on $W$, then the following are satisfied:

1. $r(\text{supp}(f) \cap (G \setminus K)) \cup s(\text{supp}(f) \cap (G \setminus K)) \subseteq W$ for all $f \in F$,
2. $||(1-p)f(1-p)|| > ||f|| - \varepsilon$ for all $f \in F$, and
3. $\tau(p) < \varepsilon$ for all $\tau \in T(C_r^+(G))$.

**Proof** By [14, Corollary 2.4], the condition about the existence of a full-supported invariant measure $\nu$ guarantees that the associated regular representation $\pi : C_r^+(G) \to B(L^2(G, \nu))$ is injective.

Using that, write $F = \{f_1, \ldots, f_k\}$, and choose functions $\xi_1, \ldots, \xi_k, \eta_1, \ldots, \eta_k \in C_c(G)$ such that $||\xi_i|| = ||\eta_i|| = 1$ and $|\langle \pi(f_i)\xi_i, \eta_i \rangle| > ||f_i|| - \varepsilon$ for all $1 \leq i \leq k$. Consider the compact set

$$C := \bigcup_{i=1}^k \text{supp}(f_i) \cup \text{supp}(f_i^*) \cup \text{supp}(\xi_i) \cup \text{supp}(\eta_i).$$

Since $G$ is ample, we can cover $C$ by finitely many compact open bisections $V_1, \ldots, V_l$ and we let $V := V_1 \cup \cdots \cup V_l$. Let $0 < \delta < \varepsilon$ to be determined. As $G$ is almost finite, we can find a $(V \cup V^{-1}, \frac{\delta}{2l})$-invariant elementary subgroupoid $K \subseteq G$. Let $W := r(V \setminus K) \cup s(V \setminus K)$ (which depends on the choice of $\delta$). Then (1) is clearly satisfied by $W$. Moreover, if $\tau \in T(C_r^+(G))$, then there exists a $\mu \in M(G)$ such that $\tau(\chi_A) = \mu(A)$ for every compact open subset $A \subseteq G^{(0)}$. By [28, Lemma 3.8] we have $\mu(r(V_i \setminus K)) < \frac{\delta}{2l}$ and $\mu(s(V_i \setminus K)) < \frac{\delta}{2l}$ for all $1 \leq i \leq l$, and hence

$$\tau(p) = \mu(W) \leq \sum_{i=1}^l \mu(r(V_i \setminus K)) + \mu(s(V_i \setminus K)) < \delta < \varepsilon.$$

It remains to check (2): Let $R := \max_{1 \leq i \leq l} \sup_{x \in G^{(0)}} \sum_{y \in G^{(0)}} \sum_{g \in G^r} |\xi_i(g)|^2$. Then we have
\[ \| \pi(1-p)\xi_i - \xi_i \|^2 = \| \pi(p)\xi_i \|^2 \\
= \langle \pi(p)\xi_i, \xi_i \rangle \\
= \int \sum_{g \in G^0} p(r(g))\xi_i(g)\overline{\xi_i(g)}d\nu(x) \\
= \int \sum_{g \in G^0} |\xi_i(g)|^2d\nu(x) \leq \nu(W)R < R\delta. \]

Similarly, \( \| \pi(1-p)\eta_i - \eta_i \| < R'\delta \) with \( R' \) chosen as \( R \), but with the \( \xi_i \) replaced by \( \eta_i \). Using this and that \( |\langle \pi(f_i)\xi_i, \eta_i \rangle| > \| f_i \| - \epsilon \), we can choose \( \delta \) (and hence \( W \) and \( p \)) so small, such that
\[ |\langle \pi(f_i)\pi(1-p)\xi_i, \pi(1-p)\eta_i \rangle| > \| f_i \| - \epsilon \]
for \( 1 \leq i \leq k \). Hence, we get
\[ \| (1-p)f_i(1-p) \| = \| \pi((1-p)f_i(1-p)) \| \geq |\langle \pi(f_i)\pi(1-p)\xi_i, \pi(1-p)\eta_i \rangle| \]
\[ > \| f_i \| - \epsilon, \]
as desired. \( \square \)

The following lemma is a local version of [22, Lemma 3.3] for finite sets of projections. The proof follows almost verbatim to [22, Lemma 3.3], just using Lemma 3.2 instead of [22, Lemma 3.1]. We include the proof for completeness.

**Lemma 3.3** Let \( G \) be an almost finite groupoid such that \( G^{(0)} \) admits a full-supported invariant measure. Then for every finite set of projections \( E = \{ e_1, \ldots, e_n \} \subseteq C^*_r(G) \) and \( \epsilon > 0 \), there exists an elementary subgroupoid \( K \subseteq G \) and projections \( q_1, \ldots, q_n \in C^*_r(K) \) such that \( q_i \preceq e_i \) and \( \tau(e_i) - \tau(q_i) < \epsilon \) for all \( \tau \in T(C^*_r(G)) \).

**Proof** Without loss of generality we may assume that \( \epsilon < 6 \). Choose \( \delta_0 > 0 \) such that whenever \( A \) is a \( C^* \)-algebra and \( p_1, p_2 \in A \) are projections with \( \| p_1p_2 - p_2 \| < \delta_0/6 \), then \( p_2 \preceq p_1 \). Let \( f : [0, \infty) \to [0, 1] \) be the continuous function given by \( f(t) = \frac{\epsilon}{t} \) for \( 0 \leq t \leq \frac{\epsilon}{6} \) and 1 otherwise. Now choose \( \delta > 0 \) such that whenever \( A \) is a \( C^* \)-algebra and \( a_1, a_2 \in A \) are positive elements with \( \| a_1 \|, \| a_2 \| \leq 1 \) and \( \| a_1 - a_2 \| < \delta \), then \( \| f(a_1) - f(a_2) \| < \delta_0/2 \).

Since \( C^*_c(G) \) is dense in \( C^*_r(G) \), there exist selfadjoint elements \( d_1, \ldots, d_n \in C^*_c(G) \) with \( \| d_i \| \leq 1 \) and
\[ \| e_i - d_i \| < \min\left( \frac{\delta}{2}, \frac{\epsilon}{6} \right), \quad 1 \leq i \leq n. \]

Now apply Lemma 3.2 to \( F = \{ d_1, \ldots, d_n \} \) and \( \epsilon > 0 \) to obtain a projection \( p = \chi_W \in C(G^{(0)}) \subseteq C^*_r(G) \) and an elementary subgroupoid \( K \subseteq G \), such that
$$r(\text{supp}(d_i) \cap (G \setminus K)) \cup s(\text{supp}(d_i) \cap (G \setminus K)) \subseteq W$$

for $i = 1, \ldots, n$, and $\tau(p) < \varepsilon/6$ for all $\tau \in T(C^*_r(K))$. Then, we have

$$(1 - p)d_i(g) = \sum_{h \in C^*_r(K)} (1 - p)(h)d_i(h^{-1}g) = (1 - p)(r(g))d_i(g),$$

which can only be nonzero if $g \in K$. Hence, we have $(1 - p)d_i \in C^*_r(K)$ and $d_i(1 - p) = ((1 - p)d_i)^* \in C^*_r(K)$. For every $\tau \in T(C^*_r(K))$, we have that $\tau(pe_i(1 - p)) = 0$. Hence,

$$\tau((1 - p)e_i(1 - p)) = \tau(e_i) - \tau(ep) \geq \tau(e_i) - \tau(p) > \tau(e_i) - \frac{\varepsilon}{6}.$$ 

Moreover, using that $\|d_i^2 - e_i^2\| \leq \|d_i^2 - d_i e_i\| + \|d_i e_i - e_i^2\| \leq \frac{\varepsilon}{3}$ we obtain that

$$\tau(d_i(1 - p)d_i) = \tau((1 - p)d_i^2(1 - p)) > \tau(e_i) - \frac{\varepsilon}{2}.$$ 

Also, each $d_i(1 - p)d_i$ is a positive element in $C^*_r(K)$. Let $g, h : [0, \infty) \to [0, 1]$ be given by

$$g(t) = \begin{cases} 0 & 0 \leq t \leq \frac{\varepsilon}{6} \\ 6\varepsilon^{-1}t - 1 & \frac{\varepsilon}{6} \leq t \leq \frac{\varepsilon}{3} \\ 1 & \frac{\varepsilon}{3} \leq t \end{cases} \quad \text{and} \quad h(t) = \begin{cases} t & 0 \leq t \leq \frac{\varepsilon}{6} \\ \frac{\varepsilon}{6} \leq t \leq \frac{\varepsilon}{3} \\ \frac{\varepsilon}{3} \leq t \end{cases}$$ 

Then put $a_i := f(d_i(1 - p)d_i)$, $b_i := g(d_i(1 - p)d_i)$, and $c_i := h(d_i(1 - p)d_i)$. It follows that $a_i, b_i, c_i \in C^*_r(K)$ are positive elements for all $1 \leq i \leq n$. Moreover, we have the following relations: $a_i b_i = b_i$, $b_i + c_i \geq d_i(1 - p)d_i$, $\|a_i\| \leq 1$, $\|b_i\| \leq 1$ and $\|c_i\| \leq \frac{\varepsilon}{6}$. In particular we have $\tau(c_i) \leq \frac{\varepsilon}{6}$ for every $\tau \in T(C^*_r(K))$, whence

$$\tau(b_i) = \tau(b_i + c_i) - \tau(c_i) \geq \tau(d_i(1 - p)d_i) - \frac{\varepsilon}{6} > \tau(e_i) - \frac{2\varepsilon}{3}.$$ 

Now use the fact that $C^*_r(K)$ is an AF-algebra to apply [22, Lemma 3.2], which gives us projections $q_i \in \overline{b_i C^*_r(K)b_i}$ such that $a_i q_i = q_i$ and $\|q_i b_i - b_i\| < \frac{\varepsilon}{6}$. Then $\|q_i b_i q_i - b_i\| < \frac{\varepsilon}{3}$. So for every $\tau \in T(C^*_r(K))$ we have

$$\tau(q_i) \geq \tau(q_i b_i q_i) > \tau(b_i) - \frac{\varepsilon}{3} > \tau(e_i) - \varepsilon,$$

which is equivalent to $\tau(e_i) - \tau(q_i) < \varepsilon$. It remains to show, that $q_i \preceq e_i$: Since $\|d_i\| \leq 1$, we have

$$\|d_i(1 - p)d_i - e_i(1 - p)e_i\| < \|d_i(1 - p)d_i - e_i(1 - p)d_i\| + \|e_i(1 - p)d_i - e_i(1 - p)e_i\| \leq 2\|d_i - e_i\| < \delta.$$ 

The choice of $\delta$ then yields $\|a_i - f(e_i(1 - p)e_i)\| < \frac{\delta_0}{2}$. Using the equality $e_i f(e_i(1 - p)e_i) = f(e_i(1 - p)e_i)$, we obtain $\|e_i a_i - a_i\| < \delta_0$. Since $a_i q_i = q_i$, we also
have \(\|e_iq_i - q_i\| = \|e_ia_iq_i - a_iq_i\| \leq \|e_i a_i - a_i\|\|q_i\| < \delta_0\). From the choice of \(\delta_0\) we conclude that \(q_i \preceq e_i\) as desired. \(\square\)

The following Lemma is the special tool needed to show Theorem 3.1.

**Lemma 3.4** Let \(K\) be an elementary groupoid. Then for each projection \(p \in C^*_r(K)\) there exists a projection \(q \in C(K^{(0)})\) such that \(p \sim q\).

**Proof** We know that \(C^*_r(K) \cong \bigoplus_{i=1}^n M_{n_i}(C(A_i))\) for some \(n_i \in \mathbb{N}\) and pairwise disjoint clopen subsets \(A_1, \ldots, A_n \subseteq K^{(0)}\). Hence, it is enough to prove the claim for an algebra of the form \(M_n(C(X))\) for a compact and totally disconnected Hausdorff space \(X\). So let \(p \in M_n(C(X))\) be a projection. We may assume that \(p \neq 0\), otherwise there is nothing to prove. Then \(x \mapsto \text{Tr}(p(x))\) is an integer valued continuous function on \(X\). Using continuity and the fact that \(X\) is compact and totally disconnected, we can find \(r \in \mathbb{N}\), a partition \(X = X_1 \sqcup \cdots \sqcup X_r\) of \(X\) by clopen subsets, and \(0 < n_1 < \cdots < n_r \in \mathbb{N}\) such that \(\text{Tr}(p(x)) = n_i\) for all \(x \in X_i\). Note, that we must have \(n_r \leq n\). For each \(1 \leq i \leq r\), let \(X_i \subseteq C(X)\) denote the characteristic function on \(X_i\). Set \(n_0 := 0\) and \(n_{r+1} := n\) to make the following definition consistent: for each \(1 \leq i \leq r\) let \(q_i \in M_{n_i-n_{i-1}}(C(X))\) be the diagonal matrix

\[
q_i := \begin{pmatrix}
\sum_{j=1}^r X_j & 0 \\
0 & \sum_{j=1}^r X_j
\end{pmatrix}.
\]

Each \(q_i\) is a projection, since the characteristic functions \(X_j\) are pairwise orthogonal. Define \(q := \text{diag}(q_1, \ldots, q_r, 0) \in M_n(C(X))\). Then \(q\) is a projection and \(\text{Tr}(q(x)) = \text{Tr}(p(x))\) for all \(x \in X\). Since \(X\) is totally disconnected, the result follows from [26, Exercise 3.4]. \(\square\)

**Theorem 3.1** Let \(G\) be an almost finite groupoid such that \(G^{(0)}\) admits a full-supported invariant measure. If \(x \in K_0(C^*_r(G))\) satisfies \(\tau_x(x) > 0\) for all \(\tau \in T(C^*_r(G))\), then there exists a projection \(e \in M_{\infty}(C^*_r(G))\) such that \(x = [e]\).

**Proof** Write \(x = [q] - [p]\) for two projections \(p, q \in M_n(C^*_r(G))\) for some large enough \(n \in \mathbb{N}\). Replacing \(G\) by \(G \times \{1, \ldots, n\}^2\) and using that \(C^*_r(G \times \{1, \ldots, n\}^2) \cong M_n(C^*_r(G))\), we may assume that \(p, q \in C^*_r(G)\). Since \(T(C^*_r(G))\) is weak*-compact, there exists \(\varepsilon > 0\) such that \(\tau(q) - \tau(p) = \tau_x(x) > \varepsilon\) for all \(\tau \in T(C^*_r(G))\). Now we apply Lemma 3.3 to \(E = \{q, 1 - p\}\) to obtain an elementary subgroupoid \(K \subseteq G\) and projections \(q_0, f_0 \in C^*_r(K)\) such that \(q_0 \preceq q\) and \(f_0 \preceq 1 - p\) and \(\tau(q) - \tau(q_0) < \frac{\varepsilon}{3}\) and \(\tau(1 - p) - \tau(f_0) < \frac{\varepsilon}{3}\). Combining these three inequalities we get

\[
\tau(q_0) - \tau(1 - f_0) > \frac{\varepsilon}{3} > 0 \quad \forall \tau \in T(C^*_r(G)).
\]

Now since \(K\) is an elementary subgroupoid of \(G\), we can invoke Lemma 3.4 to find projections \(q_1, f_1 \in C(G^{(0)})\) such that \(q_1 \sim q_0 \preceq q\) and \(f_1 \sim f_0 \preceq 1 - p\). Hence,
\[ \tau(q_1) - \tau(1-f_1) > 0 \forall \tau \in T(C^*_r(G)). \]

By Proposition 3.1 every trace corresponds to a \( G \)-invariant measure and vice versa. Since \( q_1, f_1 \) must be the characteristic functions of some clopen subsets of \( G^{(0)} \), it follows from [2, Lemma 3.7] that \( 1-f_1 \) is Murray–von Neumann subequivalent to \( q_1 \). Let \( q_2 \in C^*_r(G) \) be a projection such that \( 1-f_1 \sim q_2 \leq q_1 \). Since \( q_1 \preceq q \), there exists a projection \( q' \in C^*_r(G) \) such that \( q_1 \sim q' \leq q \) and since \( f_1 \preceq 1-p \) there exists \( f' \in C^*_r(G) \) such that \( f_1 \sim f' \leq 1-p \). Then

\[
x = [q] - [p] = ([q] - [q_1]) + ([q_1] - [q_2]) + ([q_2] - [p]) \\
= [q - q'] + [q_1 - q_2] + [1 - p - f'] > 0,
\]

which concludes the proof. \( \square \)

As an easy application of Theorem 3.1 and the main theorem in [28], we deduce the following corollary. Recall that a C*-algebra \( A \) has comparison of projections if, for projections \( p, q \in M_\infty(A) \), we have \( p \preceq q \) whenever \( \tau(p) < \tau(q) \) for all \( \tau \in T(A) \).

**Corollary 3.1** If \( G \) is a minimal almost finite groupoid, then \( C^*_r(G) \) has comparison of projections.

**Proof** If \( \tau(p) < \tau(q) \) for all \( \tau \in T(C^*_r(G)) \), then by Theorem 2.6 we have \( [q] - [p] = [e] \) in \( K_0(C^*_r(G)) \) for some projection \( e \). In other words, \( [q] = [p \oplus e] \). Since \( C^*_r(G) \) has stable rank one by [28, Main Theorem], we have that \( q \) is Murray–von Neumann equivalent to \( p \oplus e \geq p \), which concludes the proof. \( \square \)

Let us now turn our attention to the real rank of \( C^*_r(G) \). We need the following technical result inspired by [22, Lemma 4.1].

**Lemma 3.5** Let \( G \) be an almost finite groupoid. For every finite subset \( F \subseteq C_c(G) \) and \( n \in \mathbb{N} \), there exist an elementary subgroupoid \( K \subseteq G \) and a clopen subset \( W \subseteq G^{(0)} \), such that for \( p := \chi_W \in C(G^{(0)}) \) we have:

1. \( f(1-p) \) and \( (1-p)f \) are in \( C_c(K) \) for all \( f \in F \), and
2. There exist \( n \) mutually orthogonal projections \( p_1, \ldots, p_n \in C(G^{(0)}) \), such that \( p_i \sim p \) in \( C^*_r(G) \) for all \( 1 \leq i \leq n \).

**Proof** Let \( F \subseteq C_c(G) \) be a finite subset and \( n \in \mathbb{N} \). Consider the compact set \( C := \bigcup_{f \in F} \operatorname{supp}(f) \cup \operatorname{supp}(f^*) \). Find compact open bisections \( V_1, \ldots, V_l \) such that \( C \subseteq \bigcup_{i=1}^l V_i := V \). Then we can use almost finiteness of \( G \) to find \( a(V \cup V^{-1}, \frac{1}{2(n+1)f}) \) -invariant elementary subgroupoid \( K \subseteq G \). Let \( W := r(V \setminus K) \cup s(V \setminus K) \) and \( p := \chi_W \in C^*_r(G) \). Then \( p \) satisfies (1), since for all \( f \in F \) we can compute.
\[ ((1 - p)f)(g) = \sum_{h \in G^{(i)}} (1 - p)(h)f(h^{-1}g) = (1 - p)(r(g))f(g), \]

and the latter quantity can only be non-zero if \( g \in K \) by the definition of \( p \). Similar reasoning yields \( f(1 - p) \in C_c(K) \).

We now aim to show that \( p \) also satisfies (2). To this end we first show the following intermediate claim, which basically says that in any given tower of a castle for \( K \) that intersects \( W \), we have enough levels to allow for at least \( n \) pairwise disjoint copies of \( W \) all equivalent in the dynamical sense to \( W \).

Before that, recall that by the same arguments as in the proof of Lemma 3.2 we have

**Claim 1** There exists \( 0 < \varepsilon < \frac{1}{n+1} \), a compact subset \( L \subseteq G \) and a \((L, \varepsilon)\)-invariant elementary subgroupoid \( K' \subseteq G \) admitting a clopen castle

\[ G^{(0)} = \bigcup_{i=1}^{N} \bigcup_{j=1}^{N_i} F_{j}^{(i)}, \quad K' = \bigcup_{i=1}^{N} \bigcup_{l,k=1}^{N_i} V_{k,l}^{(i)}, \]

such that for all \( 1 \leq i \leq N \) we have

\[ N_i > (n + 1) \cdot \left| \{ j \mid F_{j}^{(i)} \cap W \neq \emptyset \} \right|. \]

**Proof** Suppose the claim is not true. Using almost finiteness, for every \( 0 < \varepsilon < \frac{1}{n+1} \) and compact subset \( L \subseteq G \), there exists a \( m := (L, \varepsilon)\)-invariant elementary subgroupoid \( K_m \subseteq G \) admitting a clopen castle. By refining the tower-decomposition according to [2, Lemma 3.4], we may as well assume that every level of every tower of the castle is either contained in or disjoint from \( W \). Since we assumed that the claim is not true, in each such clopen castle there must be at least one tower for which the inequality (2) does not hold. Denoting the mentioned tower (and levels) by \( F_m := (F_{j}^{(i,m)}, \theta_{j,k}^{(i,m)})_{1 \leq j,k \leq N_m} \), let \( x_m \in F_{1}^{(i_m)} \) and define the associated probability measure on \( B \subseteq G^{(0)} \) by

\[ \mu_m(B) = \frac{1}{N_m} \sum_{j=1}^{N_m} \delta_{x_m} \left( \theta_{1,j}^{(i_m)}(B \cap F_{j}^{(i_m)}) \right). \]

Then, using that inequality (2) does not hold, for all \( m \) we have that

\[ \mu_m(W) \geq \frac{1}{N_m} \sum_{j=1}^{N_m} \mu_m(F_{j}^{(i_m)} \cap W) = \frac{\left| \{ j \mid F_{j}^{(i_m)} \cap W \neq \emptyset \} \right|}{N_m} \geq \frac{1}{n+1}. \]

Then, it can be verified that any weak-\( \ast \)-cluster point of the net \( (\mu_m)_m \) is a \( G \)-invariant probability measure on \( G^{(0)} \) (see the proof of [2, Lemma 3.7] for more details). If
\( \mu \in M(G) \) is one of those, it also satisfies \( \mu(W) \geq \frac{1}{n+1} \); thus, it contradicts the inequality (1).

Now suppose we are given a clopen castle as in the claim with associated partial homeomorphisms \( \theta_{kj}^{(i)} \) implemented by the bisections \( V_{k,l}^{(i)} \). For ease of notation, let \( l_i := |\{ j \mid F_j^{(i)} \cap W \neq \emptyset \}| \). We can relabel the levels if necessary to assume that \( W \) sits at the bottom of each tower, i.e. \( F_j^{(i)} \cap W = \emptyset \) if and only if \( j > l_i \) for all \( 1 \leq i \leq N \). Then, for each \( 1 \leq k \leq n \) let

\[
W_k := \bigcup_{i=1}^{N} \bigcup_{j=1}^{l_i} \theta_{kl_i+j}^{(i)}(F_j^{(i)} \cap W).
\]

Let \( p_k := \chi_{W_k} \) be the associated characteristic function. Then the \( p_k \) are obviously all pairwise orthogonal and by construction \( p_k \sim G p_0 = p \) for all \( k \in \{0, \ldots, n\} \). In particular, the \( p_k \) are all Murray–von Neumann equivalent.

We can now follow the proof of [22, Theorem 4.6] by using Lemma 3.5 and Theorem 3.1 to get the following:

**Theorem 3.2** If \( G \) is a minimal almost finite groupoid, then \( C^*_r(G) \) has real rank zero.

**Proof** Let \( a \in C^*_r(G) \) be a selfadjoint element with \( \|a\| \leq 1 \). We want to approximate \( a \) by an invertible selfadjoint element. Invoking a short density argument, we may assume that \( a \in C_c(G) \). Moreover, we assume \( 0 \in sp(a) \) since for an invertible element \( a \), there is nothing to prove. Let \( \varepsilon > 0 \) be given. Choose continuous functions \( f, g : [-1, 1] \to [0, 1] \) such that \( g(0) = 1, fg = g \), and \( \text{supp}(f) \subseteq (-\frac{1}{2} \varepsilon, \frac{1}{2} \varepsilon) \). Let

\[
\alpha := \inf_{\tau \in T(C^*_r(G))} \tau(g(a)).
\]

Since \( G \) is minimal and almost finite, \( C^*_r(G) \) is simple. Hence all traces on \( C^*_r(G) \) are faithful. Combining this with the facts that \( g(a) \) is a nonzero positive element, and \( T(C^*_r(G)) \) is weak* compact, we obtain \( \alpha > 0 \). Find \( 0 < \delta < \frac{\varepsilon}{\alpha} \) from [22, Lemma 4.4] applied to \( r = 1, g \), and \( \frac{1}{4} \alpha \). Now let \( m \in \mathbb{N} \) with \( m > \frac{2}{\delta} \). By Lemma 3.5 we can find an elementary subgroupoid \( K \subseteq G \) and a projection \( p_0 \in C(G^{(0)}) \), such that \( a(1 - p_0), (1 - p_0) a \in C_c(K) \) and such that \( p_0 \) is Murray–von Neumann equivalent in \( C^*_r(G) \) to more than \( 8m\alpha^{-1} \) mutually orthogonal projections in \( C(G^{(0)}) \). In particular \( \tau(p_0) < \frac{1}{\delta} \alpha m^{-1} \) for all \( \tau \in T(C^*_r(G)) \).

Define \( b = a - p_0 a p_0 \). Then \( b \) is a selfadjoint element of \( C_c(K) \) with \( \|b\| \leq 2 \). By our choice of \( \delta \), and the fact that \( C^*_r(K) \) is an AF algebra, we can apply [22, Lemma 4.3] to \( b, p_0 \) and \( \frac{1}{2} \delta \) to obtain a projection \( p \in C^*_r(K) \) such that \( \|pb - bp\| < \delta \), \( p_0 \leq p \) and \( [p] \leq 2m[p_0] \) in \( K_0(C^*_r(G)) \). Now \( p \) commutes with \( a - b = p_0 a p_0 \), so also \( \|pa - ap\| < \delta \). Furthermore, because \( p \in C^*_r(K) \) and \( p \geq p_0 \), we get \( (1 - p)a, a(1 - p) \in C^*_r(K) \).

Define \( a_0 := (1 - p)a(1 - p) \). For every \( \tau \in T(C^*_r(G)) \), we have
\[ \tau(p) \leq 2m\tau(p_0) < \frac{1}{4} \alpha. \]

By the choice of \( \delta \) and using [22, Lemma 4.4], we get
\[ \tau(g(a_0)) > \tau(g(a)) - \tau(p) - \frac{1}{4} \alpha \geq \alpha - \frac{1}{4} \alpha - \frac{1}{4} \alpha = \frac{1}{2} \alpha \quad \forall \tau \in T(C_r^*(G)). \]

Also \( f(a_0)g(a_0) = g(a_0) \), and \( C_r^*(K) \) is an AF algebra, so [22, Lemma 3.2] provides a projection \( q \in C_r^*(K) \) such that
\[
q \in g(a_0)C_r^*(K)g(a_0), \quad f(a_0)q = q, \quad \text{and} \quad \|qg(a_0) - g(a_0)\| < \frac{1}{8} \alpha.
\]

Therefore we have the estimate \( \|qg(a_0)q - g(a_0)\| < \frac{\alpha}{4} \). For all \( \tau \in T(C_r^*(G)) \), we have \( \tau(qg(a_0)q) \leq \tau(q) \) because \( \|g(a_0)\| \leq 1 \). Combining this with previous estimates, it follows that \( \tau(q) > \frac{1}{4} \alpha \). Combining this with our estimate for \( p \), we get that
\[ \tau(p) < \tau(q) \quad \text{for all} \quad \tau \in T(C_r^*(G)). \]

It follows from Theorem 3.1, that \( [q] - [p] = [e] \) for some projection \( e \in M_\infty(C_r^*(G)) \). Since \( C_r^*(G) \) has stable rank one (and thus cancellation of projections) by [28, Main Theorem], we have \( q \sim p + e \), which means \( p \preceq q \) in \( C_r^*(G) \).

Since \( a_0p = pa_0 = 0 \), we conclude that \( p \) and \( q \) are orthogonal. By [22, Lemma 4.5] applied to \( a_0, \lambda_0 = 0, g, \) and \( q \) we have
\[ \|qa_0 - a_0q\| < \frac{2\epsilon}{9} \quad \text{and} \quad \|qa_0q\| < \frac{\epsilon}{9}. \]

Consider now \( s := 1 - p - q \). Then
\[
a - (sas + pap) = pa(1 - p) + (1 - p)ap + qa_0s + sa_0q + qa_0q.
\]

Therefore, using that \( qs = 0 \), we have
\[
\|a - (sas + pap)\| \leq 2\|pa - ap\| + 2\|qa_0 - a_0q\| + \|qa_0q\|
\leq 2\delta + \frac{4\epsilon}{9} + \frac{\epsilon}{9} < \frac{7\epsilon}{9}.
\]

Now if \( B = (1 - s)C_r^*(G)(1 - s) \), then \( pap \) is a selfadjoint element in \( pBp = pC_r^*(G)p \) and we have \( p \preceq q = (1 - s) - p = 1_B - p \). Hence [10, Lemma 8] provides us with an invertible selfadjoint element \( b \in B \) such that \( \|b - pap\| < \frac{\epsilon}{9} \). Moreover, \( sas = s(1-p)as \in sC_r^*(K)s \), which is an AF algebra, so there is an invertible selfadjoint element \( c \in sC_r^*(K)s \) such that \( \|c - sas\| < \frac{\epsilon}{9} \). It follows that \( b + c \) is an invertible selfadjoint element in \( C_r^*(G) \) such that
\[
\|a - (b + c)\| \leq \|a - (sas + pap)\| + \|b - pap\| + \|c - sas\|
\leq \frac{7\epsilon}{9} + \frac{\epsilon}{9} + \frac{\epsilon}{9} = \epsilon,
\]

which completes the proof. \( \square \)
Stable rank one for C*-algebras associated to minimal almost finite groupoids [28, Main Theorem] is a crucial ingredient in the proof of Theorem 3.1 and Theorem 3.2. Notice that this strategy does not hold for general non-minimal almost finite groupoids since they usually do not have stable rank one (see e.g. [4, 17, 23] for examples and further results in this direction).

Finally, we are ready to provide a proof of the main theorem by combining the above results:

**Proof of Theorem 1.1** First of all, we notice that $C^*_r(G)$ is a unital simple C*-algebra with stable rank one and real rank zero (see [5, Corollary 3.14], [20, Remark 6.6], [28, Main Theorem] and Theorem 3.2). Therefore, its Cuntz semigroup is $\text{Cu}(C^*_r(G)) \cong A_\varphi(V(C^*_r(G)))$ [1, Theorem 6.4], where the latter stands for the countably generated intervals in the projection monoid. Recall that the isomorphism is described via $\langle a \rangle \mapsto I(a) := \{p \in V(C^*_r(G)) \mid p \in aM_{\infty}(C^*_r(G))a\}$, and that any interval $I(a)$ has an increasing countable cofinal subset of projections $\{[p_n]\}$ in $V(C^*_r(G))$ such that $\langle a \rangle = \sup([p_n])$ in $\text{Cu}(C^*_r(G))$.

Let us now fix $\langle a \rangle, \langle b \rangle \in \text{Cu}(C^*_r(G))$ such that $d_\tau(a) < d_\tau(b)$ for all $\tau \in T(C^*_r(G))$. Let $\langle a \rangle = \sup([p_n])$ and $\langle b \rangle = \sup([q_m])$, where all $[p_n], [q_m]$ in $V(C^*_r(G))$. Given $\tau \in T(C^*_r(G))$ and $n \in \mathbb{N}$, it is clear by construction that $\tau(p_n) = d_\tau(p_n) < d_\tau(b)$. Hence, there is $N(n, \tau) \in \mathbb{N}$ such that $\tau(p_n) < \tau(q_{N(n, \tau)})$. Now, using that $T(C^*_r(G))$ is compact under the weak-* topology, we find $N(n) \in \mathbb{N}$ such that $\tau(p_n) < \tau(q_{N(n)})$ for all $\tau \in T(C^*_r(G))$. By Corollary 3.1, one obtains that $[p_n] \leq [q_{N(n)}]$. As this can be done for all $n \in \mathbb{N}$, $C^*_r(G)$ has strict comparison.

For the second statement, $C^*_r(G)$ is a separable non-elementary unital simple C*-algebra with stable rank one. Hence, this part follows from [29, Corollary 8.12].

\[ \square \]

**Remark 3.1** It is worth noticing that $C^*_r(G)$ in Theorem 1.1 may not be nuclear in general, as Gabor Elek constructed non-amenable minimal almost finite ample groupoids in [9, Theorem 6]. In [2, Corollary 4.12], we construct an almost finite ample principal non-minimal groupoid $G$ from coarse geometry such that $G$ is not even a-T-menable.

Let us finish providing here an almost finite ample principal non-minimal groupoid $G$ such that $C^*_r(G)$ is not exact. Indeed, take $X$ to be one of the expanders from [32, Corollary 3] such that its uniform Roe algebra $C^*_u(X)$ is not $(K)$-exact. Then $Y = X \times \mathbb{N}$ defined as in [2, Proposition 4.10] contains $X$ as a subspace by construction, and $Y$ admits tilings of arbitrary invariance. Hence, the associated coarse groupoid $G(Y)$ is almost finite by [2, Theorem 4.5]. On the other hand, $C^*_u(X)$ is a C*-subalgebra of $C^*_r(G(Y)) = C^*_u(Y)$. Since exactness passes to C*-subalgebras, $C^*_r(G(Y))$ cannot be exact as desired.
