1. Introduction and Preliminaries

Consider the system of matrix equations of the form

\[\Omega_1(X) + A^*P_1(X)A + B^*P_2(X)B = Q, \quad (1)\]
\[\Omega_2(X) + C^*Q_1(X)C + D^*Q_2(X)D = Q, \quad (2)\]

where \(Q\) is an \(n \times n\) Hermitian positive definite matrix (HPD, for short), \(A, B, C,\) and \(D\) are complex matrices of order \(n \times n\), \(\Omega_i(X), \Omega_2(X), P_1(X), P_2(X), Q_1(X),\) and \(Q_2(X)\) are mappings from the set of positive definite matrices to itself, and \(A^*\) is the conjugate transpose of \(A\).

We can see that the above equations incorporate a few linear as well as nonlinear matrix equations (NMEs, in short). Over the last few decades, many researchers studied systems (1) and (2) with different types of \(P_i, Q_i,\) and \(\Omega_i, i = 1, 2.\)

For (1), \(\Omega_1(X) = X^s, P_1(X) = X^{-p_1},\) and \(P_2(X) = X^{-p_2}, p_1, p_2 \in (0, 1] \cup \mathbb{N}^+[1]\)
For (1), \(\Omega_1(X) = X, P_1(X) = X^{-1},\) and \(P_2(X) = 0 [4]\)

For (2), \(\Omega_2(X) = X^s, P_1(X) = X^{-p_1},\) and \(P_2(X) = X^{-p_2}, p_1, p_2 \in (0, 1] \cup \mathbb{N}^+[7]\)
For (2), \(\Omega_2(X) = X, P_1(X) = X^{-1},\) and \(P_2(X) = 0 [8]\)

For (1), \(\Omega_1(X) = X, P_1(X) = X^{-1},\) and \(P_2(X) = X^{-1}, s, t \in \mathbb{N} [5, 6]\)
For (1), \(\Omega_1(X) = X^s, P_1(X) = P^{-p_1},\) and \(P_2(X) = X^{-p_2}, s, p_1, p_2 \geq 1 [7]\)
For (1) and (2), \(\Omega_1(X) = \Omega_2(X) = X, Q_1(X) = X^{-p_1}, P_1(X) = X^{-p_2},\)
\(Q_2(X) = Q_2(X) = O, Q = I\) and \(P_1, P_2 \in 1^* [9, 10]\)
For (1) and (2), \(\Omega_1(X) = \Omega_2(X) = X, Q_1(X) = \pm X^{-p_1},\)
\(Q_2(X) = Q_2(X) = O, Q = I\) and \(P_1, P_2 \in 1^* [11]\)

For different types of applications of the Riccati equation, one can check [4, 12, 13].

Throughout the article, \(\mathbb{R}\) denotes the set of real numbers, \(\mathbb{N}\) denotes the set of natural numbers, \(\mathbb{R}_+ = [0, +\infty),\) 1, denotes the set of positive numbers, and \(\mathbb{N}^* = \mathbb{N} \cup \{0\}.\)

\(H(n)\) (resp. \(K(n)\) and \(P(n)\)) denotes the set of all \(n \times n\) Hermitian (resp. positive semidefinite and positive definite) matrices over \(C\) and \(M(n)\) stands for the set of all \(n \times n\) matrices over \(C.\)
For a matrix $D \in H(n)$, $s_1(D) \geq s_2(D) \geq \cdots \geq s_n(D)$ denotes its singular values and $\|D\|$ denotes the sum of these values, i.e., the trace norm of $D$. The Frobenius norm will be denoted by $\|D\|_F = (\sum_{i,j=1}^n |D_{ij}|^2)^{1/2}$. For $P, Q \in H(n)$, $P \geq Q$ (resp. $P > Q$) indicates that $P - Q$ is positive semidefinite (resp. positive definite). $O$ and $I$ stand for the zero and unit matrix in $H(n)$, respectively.

2. Conditions in Support of the Existence of a Positive Definite Solution

We begin with two useful lemmas.

**Lemma 1** (see [14]). If $P$ and $Q > 0$ are Hermitian matrices having the same order, then $2P - PQP \leq Q^{-1}$.

**Lemma 2** (see [15]). If $U \geq V > O$, then $U^p \geq V^p > O$, for all $p \in (0, 1]$.

Now, let us consider the system of NMEs of the form

$$X_1 + A^*X_1^{-1}A + B^*X_2^{-1}B = I,$$

$$X_2 + C^*X_1^{-1}C + D^*X_1^{-1}D = I. \tag{3}$$

Taking $Y = X_1^{-1}$ and $Z = X_2^{-1}$, the system of nonlinear matrix equation (3) is equivalent to

$$Y^{-1} + A^*YA + B^*ZB = I,$$

$$Z^{-1} + C^*ZC + D^*YD = I. \tag{4}$$

**Theorem 1.** Let $(Y, Z)$ be a positive-definite solution (PDS, for short) of (4). Then, $I \leq Y$ and $I \leq Z$.

**Proof.** Suppose that system (4) has a PDS $(Y, Z) > (O, O)$. Then, from Lemma 2,

$$A^*YA + B^*ZB \geq O,$$

$$C^*ZC + D^*YD \geq O, \tag{5}$$

which gives

$$Y^{-1} = I - A^*YA - B^*ZB \leq I,$$

$$Z^{-1} = I - C^*ZC - D^*YD \leq I. \tag{6}$$

This, in turn, implies that $I \leq Y$ and $I \leq Z$. \qed

**Remark 1.** In the case that $V > U > O$ in Lemma 3, we have

$$U^s < (P_1/p_1)^{-1}s^{-1}V^s$$

$$U^s < (P_2/p_2)^{-1}s^{-1}V^s, \tag{7}$$

hold for any $s \geq 1$.

**Theorem 2.** Suppose that system (4) has a PDS $(Y, Z)$. Then,

(i) $A^*A + B^*B < I$ and $C^*C + D^*D < I$

(ii) $Y^{-1} > A^*A$, $Y^{-1} > DD^*$, $Z^{-1} > CC^*$, and $Z^{-1} > BB^*$

(iii) $Y < (1/s_n(A)^2)I$ if $A$ is nonsingular, $Y < (1/s_n(D)^2)I$ if $D$ is nonsingular, $Z < (1/s_n(C)^2)I$ if $C$ is nonsingular, and $Z < (1/s_n(B)^2)I$ if $B$ is nonsingular.

**Proof.** To prove (i), since $(Y, Z)$ is a PDS of the NMEs (4), we have $Y \geq I$ and $Z \geq I$. Together with (4), this gives

$$A^*YA < I,$$

$$A^*Y^{1/2}Y^{1/2}A < I,$$

$$Y^{1/2}AA^*Y^{1/2} < I, \tag{10}$$

$$AA^* < Y^{-1},$$

$$B^*ZB < I,$$

$$BB^* < Z^{-1}. \tag{9}$$

Similarly, by (9), we can obtain $CC^* < Z^{-1}$ and $DD^* < Y^{-1}$.

To prove (ii), from (6), we have

$$A^*YA < I,$$

$$A^*Y^{1/2}Y^{1/2}A < I,$$

$$Y^{1/2}AA^*Y^{1/2} < I, \tag{10}$$

$$AA^* < Y^{-1},$$

$$B^*ZB < I,$$

$$BB^* < Z^{-1}. \tag{9}$$

We have

$$\frac{1}{s_1(A)}I \leq (AA^*)^{-1} \leq \frac{1}{s_n(A)}I. \tag{12}$$

Since $s_1(A)I \leq AA^* \leq s_n(A)I$, where $s_1(A)$ and $s_n(A)$ are the maximal and the minimal singular value of the matrix $A$, respectively, by (11) and (12) and Remark 1, we obtain $Y < (AA^*)^{-1} \leq (1/s_n(A)^2)I$.

For the case of nonsingular matrices $D, C$, and $B$, we can obtain similarly. \qed

**Theorem 3.** System (4) attains a PDS $(Y, Z)$ iff $A, B, C, D$ admit the subsequent factorizations:

$$A = (W^*W)^{-1/2}K_1,$$

$$B = (U^*U)^{-1/2}K_2,$$

$$C = (U^*U)^{-1/2}L_1,$$

$$D = (W^*W)^{-1/2}L_2. \tag{13}$$
where the matrices $W$ and $U$ are nonsingular and the columns

\[
\begin{pmatrix}
  W^{-*} \\
  K_1 \\
  K_2 
\end{pmatrix}
\quad
\text{and}
\quad
\begin{pmatrix}
  U^{-*} \\
  L_1 \\
  L_2
\end{pmatrix}
\]

are orthonormal. In this case, $(Y, Z) = (W^*W, U^*U)$ is a solution of (4).

Proof. If the system of NMEs (4) has a PDS $(Y, Z)$, then

$(Y, Z) = (W^*W, U^*U)$ for some nonsingular matrices $W, U$. Rewrite the equation (4) as

\[
\begin{cases}
  (W^*W)^{-1} + A^* (W^*W)A + B^* (U^*U)B = I, \\
  (U^*U)^{-1} + C^* (U^*U)C + D^* (W^*W)D = I,
\end{cases}
\]

or

\[
\begin{cases}
  (W^{-*})^*W^{-*} + [(W^*W)^{1/2}A]^* (W^*W)^{1/2}A + [(U^*U)^{1/2}B]^* (U^*U)^{1/2}B = I, \\
  (U^{-*})^*U^{-*} + [(U^*U)^{1/2}C]^* (U^*U)^{1/2}C + [(W^*W)^{1/2}D]^* (W^*W)^{1/2}D = I,
\end{cases}
\]

or equivalently

\[
\begin{pmatrix}
  W^{-*} \\
  (W^*W)^{1/2}A \\
  (U^*U)^{1/2}B \\
  U^{-*} \\
  (U^*U)^{1/2}C \\
  (W^*W)^{1/2}D
\end{pmatrix}
= I,
\]

Let

\[
\begin{aligned}
(W^*W)^{1/2}A &= K_1, \\
(U^*U)^{1/2}B &= K_2, \\
(U^*U)^{1/2}C &= L_1, \\
(W^*W)^{1/2}D &= L_2.
\end{aligned}
\]

Then,

\[
\begin{aligned}
A &= (W^*W)^{-(1/2)}K_1, \\
B &= (U^*U)^{-(1/2)}K_2, \\
C &= (U^*U)^{-(1/2)}L_1, \\
D &= (W^*W)^{-(1/2)}L_2.
\end{aligned}
\]

Now, (16) implies that

\[
\begin{pmatrix}
  W^{-*} \\
  K_1 \\
  K_2
\end{pmatrix}
\quad
\text{and}
\quad
\begin{pmatrix}
  U^{-*} \\
  L_1 \\
  L_2
\end{pmatrix}
\]

are orthonormal. Conversely, assume that $A, B, C,$ and $D$ have decomposition (13). Set $(Y, Z) = (W^*W, U^*U)$. Then,
Example 1. We can find $W, U, K_1, K_2, L_1,$ and $L_2$ (see Theorem 7.2.7, page 440, in [17]) for the following numerical experiment (2) which satisfies all the conditions of Theorem 3:

$$
W = \begin{bmatrix}
1.0355 & 0.0341 & 0.0307 \\
0.0341 & 1.0448 & 0.0359 \\
0.0307 & 0.0359 & 1.0335
\end{bmatrix},
$$

$$
U = \begin{bmatrix}
1.0314 & -0.0004 & 0.0020 \\
-0.0004 & 1.0276 & 0.0003 \\
0.0020 & 0.0003 & 1.0489
\end{bmatrix},
$$

$$
K_1 = \begin{bmatrix}
0.0446 & 0.1012 & 0.0750 \\
0.0667 & 0.1494 & 0.0809 \\
0.1614 & 0.1460 & 0.1117 \\
0.1087 & 0.0182 & 0.0888
\end{bmatrix},
$$

$$
K_2 = \begin{bmatrix}
0.0770 & 0.1376 & 0.1556 \\
0.1089 & 0.0686 & 0.0387 \\
0.2442 & 0.0011 & 0.0017 \\
-0.0059 & 0.2283 & -0.0207
\end{bmatrix},
$$

$$
L_1 = \begin{bmatrix}
0.0122 & 0.0224 & 0.2800 \\
-0.0104 & 0.0009 & -0.0024 \\
-0.0014 & -0.0171 & -0.0143 \\
0.0043 & 0.0110 & -0.1093
\end{bmatrix},
$$

Also, it is easy to derive

$$
s_1(A) = 0.2981,
$$

$$
s_1(A) = 0.0146,
$$

$$
s_1(B) = 0.2691,
$$

$$
s_1(C) = 0.048,
$$

$$
s_1(D) = 0.2692,
$$

$$
s_1(C) = 0.2227,
$$

$$
s_1(D) = 0.1065,
$$

$$
s_1(D) = 0.0101.
$$

It meets all of the requirements of Theorem 2.

3. Construction of Iteration Schemes

This section contains a new iteration scheme for the NMEs (4) in the context of [2, 11].

By pre- and postmultiplying the first and the second equation of (4), respectively, by $Y$ and $Z$, we obtain

$$
Y - Y(I - A^*YA - B^*ZB)Y = O,
$$

$$
Z - Z(I - C^*ZC - D^*YD)Z = O.
$$

After some simple calculation, we have

$$
Y = 2Y - Y(I - A^*YA - B^*ZB)Y,
$$

$$
Z = 2Z - Z(I - C^*ZC - D^*YD)Z.
$$

(23)

Apparently, $(Y, Z)$ is a solution of (23) if $(Y, Z)$ solves equation (4). Conversely, if $(Y, Z)$ is a nonsingular solution of equation (23), $(Y, Z)$ solves equation (4), too.

Thus, to attain a HPDS of (4), we need to solve (23). From (23), the iterative scheme is as follows.

$$
\begin{align*}
\tilde{Y}_n &= I - A^*Y_nA - B^*Z_nB \\
Y_{n+1} &= (2I - Y_n\tilde{Y}_n)Y_n, \\
\tilde{Z}_n &= I - C^*Z_nC - D^*Y_{n+1}D \\
Z_{n+1} &= (2I - Z_n\tilde{Z}_n)Z_n.
\end{align*}
$$

(24)

4. Convergence Analysis

This section contains the proof that the sequences $\{Y_n, Z_n\}$ generated by Algorithm 1, where $Y_0 = I$ and $Z_0 = I$ are initial conditions and converge to the minimal positive-definite solution of equation (4).

Theorem 4. Suppose that the system of NMEs (4) has a PDS and the sequence $\{Y_n, Z_n\}$ is generated by Algorithm 1 with initial values $Y_0 = I$ and $Z_0 = I$. Let the pair $(\tilde{Y}, \tilde{Z})$ be the minimal PDS of (4). Then, the sequence $\{Y_n, Z_n\}$ is well defined:

$$
\begin{align*}
Y_0 &\leq Y_1 \leq \cdots \leq Y_n \leq \cdots \leq \tilde{Y}, \\
Z_0 &\leq Z_1 \leq \cdots < Z_n \leq \cdots \leq \tilde{Z},
\end{align*}
$$

$$
\lim_{n \to \infty} Y_n = \tilde{Y},
$$

$$
\lim_{n \to \infty} Z_n = \tilde{Z}.
$$

(25)

Proof. Let $(Y, Z)$ be any PDS of the system of NMEs (4). We will prove that $O < Y_n \leq Y_{n+1} \leq Y$ and $O < Z_n \leq Z_{n+1} \leq Z$ for all $n \in \mathbb{N}^*$ using mathematical induction.

For $n = 0$, we have $Y_0 = I > 0$ and $Z_0 = I > O$. Then, by (24), we have

$$
Y_1 = 2I - I + A^*A + B^*B = I + A^*A + B^*B \geq I = Y_0,
$$

$$
Z_1 = 2I - I + C^*C + D^*Y_1D = I + C^*C + D^*Y_1D \geq I = Z_0.
$$

(26)

Following Theorem 4, $I - A^*A - B^*B > 0$. Using this condition in Lemma 1 together with NMEs (4),

$$
Y_1 = 2I - I (I - A^*A - B^*B)I
$$

$$
\leq (I - A^*A - B^*B)^{-1}
$$

$$
\leq (I - A^*YA - B^*ZB)^{-1}
$$

$$
= Y,
$$

(27)
since \((Y, Z) \geq (I, I)\). That is, \(Y_i \leq Y\). Using Lemma 2, this implies that \(I - C^* C - D^* YD \geq I - C^* ZC - D^* YD = Z^{-1} > 0\). Using this fact in Lemma 1 together with NMEs (4), we obtain
\[
Z_1 = 2I - I(I - C^* C - D^* Y_1 D)I \\
\leq (I - C^* C - D^* Y_1 D)^{-1} \\
\leq (I - C^* ZC - D^* YD)^{-1} \\
= Z.
\] (28)

Hence, \(O < Y_n \leq Y_{n+1} < Y\) and \(O < Z_n \leq Z_{n+1} \leq Z\) holds true for \(n = 0\).

Assume that \(O < Y_n \leq Y_{n+1} \leq Y\) and \(O < Z_n \leq Z_{n+1} \leq Z\) hold for \(n = k \geq 0\). Since \(I - A^* Y_{k+1} A - B^* Z_{k+1} B \geq I - A^* Y A - B^* ZB = Y^{-1} > O\), by equation (24), Lemma 1, and the fact \(Y_{k+1} > O\), we obtain
\[
Y_{k+2} = 2Y_{k+1} - Y_{k+1}(I - A^* Y_{k+1} A - B^* Z_{k+1} B)Y_{k+1} \\
\leq (I - A^* Y_{k+1} A - B^* Z_{k+1} B)^{-1} \\
\leq (I - A^* Y A + B^* ZB)^{-1} \\
= Y,
\] (29)

that is, \(Y_{k+2} \leq Y\). Then, by this condition and Lemma 2, we have
\[
I - C^* Z_{k+1} C + D^* Y_{k+2} D \geq I - C^* ZC - D^* YD = Z^{-1} > 0.
\]
Using this fact in Lemma 1 together with the NMEs (22) and the fact \(Z_{k+1} > O\), we have
\[
Z_{k+2} = 2Z_{k+1} - Z_{k+1}(I - C^* Z_{k+1} C - D^* Y_{k+2} D)Z_{k+1} \\
\leq (I - C^* Z_{k+1} C - D^* Y_{k+2} D)^{-1} \\
\leq Z.
\] (30)

Also, from the NMEs (24), we get that
\[
Y_{k+2} - Y_{k+1} = Y_{k+1}(I - A^* Y_{k+1} A - B^* Z_{k+1} B)Y_{k+1} \\
= Y_{k+1}[Y_{k+1}^{-1} - (I - A^* Y_{k+1} A - B^* Z_{k+1} B)]Y_{k+1}.
\] (31)

Next, by using the fact \(I - A^* Y_{k+1} A - B^* Z_{k+1} B \geq I - A^* Y_{k+1} A - B^* Z_{k+1} B > O\) together with the NMEs (24), Lemma 1, and the fact \(Y_{k+1} > 0\), it follows that
\[
Y_{k+1} = 2Y_k - Y_k(I - A^* Y_k A - B^* Z_k B)Y_k \\
\leq (I - A^* Y_k A - B^* Z_k B)^{-1} \\
\leq (I - A^* Y_{k+1} A - B^* Z_{k+1} B)^{-1},
\] (32)

that is, \(Y_{k+1} \leq (I - A^* Y_{k+1} A - B^* Z_{k+1} B)^{-1}\) and \(Y_{k+1} \leq I - A^* Y_{k+1} A - B^* Z_{k+1} B\). Using this fact with \(Y_{k+1} > O\) in equation (31), we have \(Y_{k+2} \geq Y_{k+1}\). Using this fact with Lemma 2, we have
\[
I - C^* Y_{k+1} C - D^* Y_{k+1} D \geq I - C^* Y_{k+1} C - D^* Y_{k+2} D > O.
\] (33)

This fact, together with the NMEs (24), Lemma 1, and the fact \(Z_{k+1} > O\), yields
\[
Z_{k+1} = 2Z_{k+1} - Z_{k+1}(I - C^* Z_{k+1} C - D^* Y_{k+1} D)Z_{k+1} \\
\leq (I - C^* Z_{k+1} C - D^* Y_{k+1} D)^{-1} \\
\leq (I - C^* Z_{k+1} C - D^* Y_{k+2} D)^{-1},
\] (34)

that is, \(Z_{k+1} \leq (I - C^* Z_{k+1} C - D^* Y_{k+1} D)^{-1}\) or \(Z_{k+1} \leq I - C^* Z_{k+1} C - D^* Y_{k+2} D\). Therefore,
\[
Z_{k+2} - Z_{k+1} = Z_{k+1} - Z_{k+1}(I - C^* Z_{k+1} C - D^* Y_{k+2} D)Z_{k+1} \\
= Z_{k+1}[Z_{k+1}^{-1} - (I - C^* Z_{k+1} C - D^* Y_{k+2} D)]Z_{k+1} \geq O.
\] (35)

From the above, \(O < Y_n \leq Y_{n+1} \leq Y\) and \(O < Z_n \leq Z_{n+1} \leq Z\) hold for \(n = k + 1\).

Thus, by using the principle of induction, we have that the relations \(O < Y_n \leq Y_{n+1} \leq Y\) and \(O < Z_n \leq Z_{n+1} \leq Z\) hold for \(n \in \mathbb{N}^*\). So, the sequence \(\{Y_n, Z_n\}\) is well defined, increasing, and bounded above. Let
\[
\lim_{n \rightarrow \infty} Y_n = \bar{Y}, \\
\lim_{n \rightarrow \infty} Z_n = \bar{Z}.
\] (36)

Then, \((\bar{Y}, \bar{Z})\) is a PDS of the NMEs (4) by Algorithm 1. Since \((\bar{Y}, \bar{Z}) \leq (Y, Z)\) for any PDS \((Y, Z)\) of NMEs (4), \((\bar{Y}, \bar{Z})\) is the minimal PSD of NMEs (4). \(\square\)

Remark 2. If \((\bar{X}_1, \bar{X}_2)\) is the maximal PDS of the system of NMEs (3), then by the relationship between the NMEs (3) and (4), we get that \((\bar{X}_1, \bar{X}_2)\) is the minimal PDS of NMEs (4). Therefore, from Theorem 4, the sequence \(\{Y_n, Z_n\}\) generated by Algorithm 1 with the initialization \(Y_0 = I\) and \(Z_0 = I\) converges to the inverse of the maximal PDS of NMEs (3), respectively.
5. Rate of Convergence

Lemma 4 (see [18]). If \(0 < \theta \leq 1\) and \(U, V \in P(n)\) with \(U, V \succeq I > O\), then, for every unitarily invariant norm, \(\|U^\theta - V^\theta\| \leq \theta d_{\theta - I} \|U - V\|\) and \(\|U^{-\theta} - V^{-\theta}\| \leq \theta c_{-\theta + I} \|U - V\|\).

Theorem 5. If \((Y, Z)\) is a PDS of the matrix equation (4) under Algorithm 1 and \(\varepsilon > 0\) is arbitrary, then we get the following:

(A) \[
\|Y_n - Y\| \leq (\|AY\| + \varepsilon)\|Y - Y_n\| + (\|BY\| + \varepsilon)^2\|Z - Z_n\|.
\] (37)

and

\[
Y_{n+1} = 2Y_n - Y_n(I - A^*Y_nA - B^*Z_nB)Y_n
\]
\[
= 2Y_n - Y_n[I - A^*(Y + Y_n - Y)A - B^*(Z + Z_n - Z)B]Y_n
\]
\[
= 2Y_n - Y_n[I - A^*YA - B^*ZB + A^*(Y - Y_n)A + B^*(Z - Z_n)B]Y_n
\]
\[
= 2Y_n - Y_nY^{-1}Y_n - Y_nA^*(Y - Y_n)AY_n - Y_nB^*(Z - Z_n)BY_n.
\] (41)

Thus, since \(Y - 2Y_n + Y_nY^{-1}Y_n = (Y - Y_n)Y^{-1}(Y - Y_n)\), we have

\[
Y - Y_{n+1} = (Y - Y_n)(Y - Y_n)^{-1}(Y - Y_n) + Y_nA^*(Y - Y_n)AY_n
\]
\[
+ Y_nB^*(Z - Z_n)BY_n.
\] (42)

Now, since \(\lim_{n \to \infty} Y_n = Y\), using Lemma 4, we have

\[
\|Y - Y_{n+1}\| \leq \|(Y - Y_n)(Y - Y_n)^{-1}(Y - Y_n)\| + \|Y_nA^*(Y - Y_n)AY_n\|
\]
\[
+ \|Y_nB^*(Z - Z_n)BY_n\|
\]
\[
\leq \|(Y - Y_n)(Y - Y_n)^{-1}\|\|Y - Y_n\| + \|Y_nA^*AY_n\|^2\|Y - Y_n\| + \|Y_nB^*(Z - Z_n)BY_n\|
\]
\[
\leq \|(Y - Y_n)\|\|Y - Y_n\| + \|BY_n\|^2\|Z - Z_n\|
\]
\[
\leq (\|AY\| + \varepsilon)^2\|Y - Y_n\| + (\|BY\| + \varepsilon)^2\|Z - Z_n\|.
\] (43)

which is (35).

Since

\[
\overline{Y}_n - Y^{-1} = A^*(Y - Y_n)A + B^*(Z - Z_n)B,
\] (44)

using Lemma 4, we have relation (38).

In the same way, we can prove (B). \(\square\)

6. Numerical Examples

Two examples are presented in this section in support of Algorithm 1. Take Residue = \(\|Y_{n+1} - Y_n\| + \|Z_{n+1} - Z_n\|\), tolerance = \(10^{-10}\), and norm as Frobenius norm. For comparative analysis, a basic fixed point algorithm (BFP, for short) has been used:

After applying Algorithm 1 with the initial conditions \(Y_0 = I\) and \(Z_0 = I\), we obtain \(X_1 = \begin{bmatrix} 0.9379 & -0.0581 & -0.0526 \\ -0.0581 & 0.9221 & -0.0617 \\ -0.0526 & -0.0617 & 0.9418 \end{bmatrix}\), and \(X_2 = \begin{bmatrix} 0.9401 & 0.0007 & -0.0035 \\ 0.0007 & 0.9470 & -0.0006 \\ -0.0035 & -0.0006 & 0.9909 \end{bmatrix}\).
Table 1 presents a comparison between our algorithm and the basic fixed point algorithm.

Figures 1 and 2 represent CPU time graph and iteration vs. error graph.

Figures 3 and 4 represent pie chart for average CPU time based on ten experiments and solution’s surface plot.

**Example 3.** In the current example, a new, randomly chosen set of coefficients $A, B, C, D \in C^{r \times r}$ is used. The construction is followed by

\[
\begin{align*}
A_t(i, j) &= \frac{r}{i+j-1}, \\
B_t(i, j) &= \frac{r}{1} \times A_t(i, j), \\
C_t(i, j) &= \frac{r^2}{i+j-1}, \\
D_t(i, j) &= \frac{1}{r-1} \times A_t(i, j), \\
Q_t(i, j) &= I(i, j) + A_t(i, j) \times A_t(i, j), \\
Q_2(i, j) &= I(i, j) + B_t(i, j) \times B_t(i, j), \\
A_1(i, j) &= Q_1(i, j)^{(1/2)} \times A_t(i, j) \times Q_1(i, j)^{(1/2)}, \\
B_1(i, j) &= Q_1(i, j)^{(1/2)} \times B_t(i, j) \times Q_1(i, j)^{(1/2)}, \\
C_1(i, j) &= Q_2(i, j)^{(1/2)} \times C_t(i, j) \times Q_2(i, j)^{(1/2)}, \\
D_1(i, j) &= Q_2(i, j)^{(1/2)} \times D_t(i, j) \times Q_2(i, j)^{(1/2)}.
\end{align*}
\]

\[
\begin{align*}
N_1 &= \text{norm}(A_1^* \times A_1 + B_1^* \times B_1, \text{fro}), \\
N_2 &= \text{norm}(C_1^* \times C_1 + D_1^* \times D_1, \text{fro}).
\end{align*}
\]

\[
\begin{align*}
A &= \frac{1}{r} \times \left( \frac{A_1}{N_1} + \frac{B_1}{N_1} \right), \\
B &= \frac{1}{r} \times \left( \frac{B_1}{N_1} + \frac{A_1}{N_1} \right), \\
C &= \frac{1}{r} \times \left( \frac{C_1}{N_2} + \frac{D_1}{N_1} \right), \\
D &= \frac{1}{r} \times \left( \frac{C_1}{N_2} + \frac{D_1}{N_1} \right).
\end{align*}
\]

Here, “$r$” and “fro” stand for dimension and Frobenius norm of the matrix, respectively. A different set of initial conditions has been chosen here as

\[
\begin{align*}
Y_0 &= \left( \frac{1}{2} \right) \times A \times \text{conjugate-transpose}(A), \\
Z_0 &= \left( \frac{1}{2} \right) \times B \times \text{conjugate-transpose}(B).
\end{align*}
\]

The result of this experiment using Algorithm 1 is shown in Table 2.

**Example 4.** Here, we consider some randomly generated matrices:

\[
\begin{align*}
A_1 &= I + \frac{1}{(2 \times r)} \text{rand}(r), \\
B_1 &= I + \frac{1}{(r^2)} \text{rand}(r), \\
C_1 &= I + \frac{1}{(r^3)} \text{rand}(r), \\
D_1 &= I + \frac{1}{(r \times 3)} \text{rand}(r),
\end{align*}
\]

where $r =$ dimension of the matrices, rand$(r) =$ random matrices of order $r$, and tol $= 1e - 10$. After applying Algorithm 1 (ALgo1) and basic fixed-point method under the initial conditions $Y_0 = I$ and $Z_0 = I$, we get Table 3 that shows the various outputs for different $r$. The 5th column of Table 3 ensures positive definiteness of Example 4 w.r.t. different order matrices.

Associated graphs are (Figures 5–25)

\text{Fig 9: it. no. vs. error} \\
\text{Fig 10: Solns surface plot'}
\end{align*}
\]

(iii) dim = 8

\[
\begin{align*}
\text{Fig 11: CPU time} \\
\text{Fig 12: it. no. vs. error} \\
\text{Fig 13: Solns surface plot'}
\end{align*}
\]

(iv) dim = 12

\[
\begin{align*}
\text{Fig 14: CPU time} \\
\text{Fig 15: it. no. vs. error} \\
\text{Fig 16: Solns surface plot'}
\end{align*}
\]
Table 1: Comparison of Algorithm 1 with basic fixed point iteration.

| Method | $r$ | No. of iteration | Error       | Average CPU time |
|--------|-----|------------------|-------------|------------------|
| Algo1  | 3   | 12               | $0.5908e-10$ | 0.0070           |
| BFP    | 3   | 12               | $0.2180e-10$ | 0.0157           |

Remark 3. We can infer from the above discussions that our algorithm is less expensive in terms of computation after evaluating these examples w.r.t. different sets of parameters.

Remark 4. We can infer from the above discussions that the solutions are positive definite.

7. Conclusion

In this study, a new iterative algorithm has been developed. All numerical tests are in agreement with the theoretical findings of this research done. Finally, based on the numerical results, we have concluded that the new iterative approach is extremely powerful and efficient in finding numerical solutions for a wide range of nonlinear matrix equations including complex ones. It also produces very accurate results with less iterations and lower computational costs, compared with the basic fixed-point approach.
