Introduction: Alcohol-based hand sanitizers containing ethanol or isopropanol are being used in order to prevent person-to-person transmission during the COVID-19. Early signs and symptoms of this ingestion include nausea, vomiting, headache, abdominal pain, blurred vision, loss of coordination, and decreased level of consciousness. After hand sanitizer ingestion we have to suspect about methanol poisoning, monitoring the start of anion-gap metabolic acidosis, seizures, and blindness is essential. Treatment includes supportive care, acidosis correction, and the administration of an alcohol dehydrogenase inhibitor. In severe cases hemodialysis may be required.

Objectives: To present a case of an 29-year-old woman who was taken to the emergency department after voluntary ingestion of alcohol-based hand sanitizer in a suicide attempt. To describe the most common side effects of hand sanitizer ingestion and the literature review.

Methods: Clinical case presentation and literature review of similar cases.

Results: A 29-year-old woman, with diagnosis of borderline personality disorder and previous suicide attempts was taken to the emergency department after 3 hours of voluntary ingestion of an unknown quantity of alcohol-based hand sanitizer. Initial laboratory findings showed laboratory a blood methanol concentration of 66 mg/dL, with an anion gap of 30 mEq/L, arterial blood pH of 7.2, serum bicarbonate concentration of 12 mEq/L. Patient complained of abdominal pain and nervousness.

Conclusions: Most common signs and symptoms of alcohol-based hand sanitizer ingestion include nausea, vomiting, headache, abdominal pain, blurred vision, loss of coordination, and decreased level of consciousness. Treatment includes supportive care, acidosis correction, the administration of an alcohol dehydrogenase inhibitor and sometimes may be required.

Introduction: Definitions used for suicide attempts and self-harm have been discussed for many years and is used differently in European countries, sometimes even interchangeably. Therefore, it is difficult to compare relevant rates across nations.

Objectives: This study aims at estimating the rate of suicide attempts and self-harm in chosen European countries in the more recent years when distinguishing between applied definitions.

Methods: A systematic search for relevant articles published between 2010-2020 will be performed in databases such as PubMed, Embase, PsycINFO, and Web of Science. Only articles in English or Danish will be included. Data will be collected for all age groups above 15 years of age. The prevalence of suicide attempts and self-harm will be calculated by a random effect model. Subgroup analyses will be performed to compare the rates according to age.

Results: from the performed systematic review and meta-study will be presented at the conference.
**Conclusions:** The conclusion will be presented when results have been analysed.

**Introduction:** The last two decades have seen the timeliness of studying the connection between suicides and drunkenness

**Objectives:** To evaluate the significance of suicidal risk factors in patients who had committed suicides while being under the effect of alcohol so as to be able to forecast suicidal risks and prevent suicides within this group

**Methods:** The authors have carried out an analysis of medical documentation of suicides committed in the Sverdlovsk region. The data on suicides has been taken from forensic expertise acts. The following factors have been taken into account: age, gender, social status of suicide victim, supplementary somatic pathology, and concentration of alcohol in the victim’s blood

**Results:** Alcoholic addiction is a behavioral indicator of suicidal risk. The level of suicidal activity in persons with the syndrome of alcoholic addiction is much higher than within the general populace. The age of 25-49 is the peak of suicidal attempts among patients with chronic alcoholism. Genuine suicides prevail during the first stage of chronic alcoholism. The patients are inclined to demonstrate pathological suicidal reactions to social displacement that show themselves in the form of conflicts within the family and at work. In addition to genuine suicidal attempts made by males in the state of abstinence

**Conclusions:** The results received confirm the role of the alcoholic factor in the formation of suicidal behavior and have the aim of elaborating new forms and methods to help prevent suicides committed in the state of alcoholic drunkenness

**Disclosure:** No significant relationships.

**Introduction:** Testosterone is an anabolic androgenic steroid hormone involved in brain development, reproduction, and social behavior. Several studies have shown that testosterone can cause impulsivity in humans. This impulsivity could modify the mood and increase the risk of suicidal behaviour.

**Objectives:** Testosterone is an anabolic androgenic steroid hormone involved in brain development, reproduction, and social behavior. Several studies have shown that testosterone can cause impulsivity in humans. This impulsivity could modify the mood and increase the risk of suicidal behaviour.

**Methods:** Clinical case and literature review.

**Results:** A 33-years male (biological female), single, gypsy ethnicity, with an 11-years daughter. Psychiatric history of one admission in a hospitalization unit. Diagnosed of depressive disorder and personality disorder NOS. Intermitent follow-up in Mental Health consultations. 8 years later, he consulted due to gender dysphoria. He refered not to be feeling identified with his body for a long time. He rejected his sexual characteristics. After his mental evaluation, he was referred to Endocrinology Service. He had been prescribed with testosterone. Three days after starting the treatment, he maked an attempt of suicide with medication. The patient had not presented previous suicide attempts or ideation. With the withdrawal of the testosterone, the suicidal behaviour dissapeared.

**Conclusions:** Due to the association of testosterone and suicidal behaviour, we consider that is important to pay attention to people who have just started the androgenic treatment in order to avoid a high risk of suicide. In the same way, we should focus on evaluating the hostility, impulsivity and irritability in patients strongly related to suicidal behaviour.

**Introduction:** Suicide rates in people diagnosed with a psychotic disorder can be up to 50 times higher than in the general population, with the lethality of attempts being significantly higher in this group, compared to people diagnosed with other psychiatric disorders. Furthermore, it is known that being male is associated with more serious suicide attempts and higher rates of completed suicides.

**Objectives:** To reflect on the increased risk of suicide associated with psychotic disorders.

**Methods:** Case report and literature review.

**Results:** Case report 40-year-old male, recently diagnosed with Schizophreniform Disorder and currently with persistent positive symptoms. He was admitted to our psychiatric hospitalization unit due to a voluntary overdose of almost 100 tablets (antihypertensives, antiarrhythmics, and benzodiazepines) and alcohol. He admits taking the pills with the aim of committing suicide. Literature review. - Around 10% of people diagnosed with schizophrenia commit suicide. - In young patients diagnosed with schizophrenia, suicide is the leading cause of death. - Between 15 and 65% of
