Abstract

Background: There are multiple studies in different countries regarding the prevalence of vitamin D deficiency. These studies showed high prevalence of vitamin D deficiency in Asian countries. This study tries to elucidate the prevalence of vitamin D deficiency and its influencing factors in population of Tehran.

Methods: 1210 subjects 20–64 years old were randomly selected. 25 (OH) D serum levels were measured. Duration of exposure to sunlight, the type of clothing and level of calcium intake and BMI were quantified based on a questionnaire.

Results: A high percentage of vitamin D deficiency was defined in the study population. Prevalence of severe, moderate and mild Vitamin D deficiency was 9.5%, 57.6% and 14.2% respectively. Vitamin D serum levels had no significant statistical relation with the duration of exposure to sunlight, kind of clothing and BMI. Calcium intake in the normal vitamin D group was significantly higher than the other groups (714.67 ± 330.8 mg/day vs 503.39 ± 303.1, 577.93 ± 304.9, 595.84 ± 313.6). Vitamin D serum levels in young and middle aged females were significantly lower than the older group.

Conclusions: Vitamin D deficiency has a high prevalence in Tehran. In order to avoid complications of vitamin D deficiency, supplemental dietary intake seems essential.

Background

Vitamin D is an essential element for establishing and maintaining bone structure. Vitamin D deficiency results in rickets and osteomalacia. Even slight vitamin D deficiency results in secondary hyperparathyroidism and increased bone resorption [1,2]. In addition, there has
been increased attention to the physiologic importance of vitamin D in non-skeletal tissues [3].

Vitamin D is supplied by consumption of vitamin D-rich foods and by vitamin D synthesis in skin.

Natural nutrient materials are not a sufficient source of vitamin D to supply the body requirements; therefore where there is no supplementation of foodstuffs, the main source for vitamin D is produced by UV light [4,5].

Regarding the significant role of sunlight in vitamin D synthesis, it is quite logical to suggest low prevalence of vitamin D deficiency in tropical countries. However the studies carried out in the preceding two decades have shown a high prevalence of vitamin D deficiency in tropical countries such as China, Turkey, India, Iran and Saudi Arabia [6-14]. The prevalence of vitamin D deficiency varied between 30% and 93%. However, the majority of these studies were limited to specific age and sex groups. Therefore, elucidation of vitamin D status at the community level and in different climates of a country seems essential.

The present study is a part of a national project of prevention, diagnosis and treatment of osteoporosis that investigates the prevalence of vitamin D deficiency and its influencing factors in the population of Tehran.

Methods
1272 healthy men and women aged 20–69 years were selected based on randomized clustered sampling from 50 blocks in Tehran.

Exclusion criteria were known hepatic or renal disease, metabolic bone disease, malabsorption, sterility, oligomenorrhea, type I diabetes, hypercortisolism, malignancy, immobility for more than one-week, pregnancy, lactation, and medications influencing bone metabolism. The study protocol was approved by research ethics committee of Endocrinology & Metabolism Research Center (EMRC). Sampling was performed after taking informed consent at the beginning of 2001 in the subjects place of residence. 1210 of 1272 selected subjects participated in this study (response rate was 95%). In the second part of study (recall for bone mineral densitometry) for 666 subjects the questionnaire was completed.

Figure 1 demonstrates vitamin D levels histogram in the study population. Total prevalence of severe, moderate and mild vitamin D deficiency was 9.5 %, 57.6% and 14.2% respectively (Figure 2).

Figure 3 demonstrates 95, 50 and 5 percentiles of vitamin D according to age and sex.

25(OH)D equal or less than 12.5 nmol/l was considered as severe vitamin D deficiency or group 1 and vitamin D more than 12.5 nmol/l and less than 25 nmol/l was considered as moderate deficiency or group 2 [15]. PTH changes in various vitamin D serum levels were applied to detect mild vitamin D deficiency which has 25 (OH)D more than 25 nmol/l and less than or equal to 35 nmol/l. Threshold for mild vitamin D deficiency was measured by applying PTH changes in different serum levels of 25(OH) D. SPSS software (version 10) was used for data analysis. In descriptive statistics 5, 50, 95 percentiles were used. Results were expressed as mean ± SD or median. To find any significant difference between groups, X2 test Kruskal-Wallis were used.

Results
In order to quantify serum levels of vitamin D and other biochemical parameters, serum samples were taken from 1210 subjects (response rate was 95%). 41% of subjects were male and 59% were female. Age and sex distribution of participants are shown in table 1. In the second part of study (recall for bone mineral densitometry) for 666 subjects the questionnaire was completed.

Figure 1 demonstrates vitamin D levels histogram in the study population. Total prevalence of severe, moderate and mild vitamin D deficiency was 9.5 %, 57.6% and 14.2% respectively (Figure 2).

Figure 3 demonstrates 95, 50 and 5 percentiles of vitamin D according to age and sex.

Serum levels of vitamin D in females above 60 years was higher than in other age groups (P < 0.001: Kruskal-Wallis test). Vitamin D serum levels in females between 20–29 years and 30–39 years was less than other age groups (P < 0.001). Median vitamin D level in females in age range of
Prevalence of high level of vitamin D (more than 150 nmol/l) in 60–69 years old female age group was significantly more than other age and sex group (P < 0.01). In recalling for bone densitometry, 666 returned (55% of study population) in whom the effect of influencing factors was evaluated. Table 2 shows mean BMI and daily calcium intake in different vitamin D groups. BMI was not significantly different in vitamin D groups but calcium intake in normal vitamin D group was significantly higher than other groups.

**Discussion**
In our study the prevalence of severe and moderate vitamin D deficiency was 9.5% and 57.6%, respectively. Mild vitamin D deficiency had a prevalence of 14.2%.

Multiple studies have been carried out about the prevalence of vitamin D deficiency but they were mostly limited to a small sample size or assessed a specific age group (especially elderly). In countries where vitamin D fortified foodstuffs are available (USA and some Scandinavian countries), prevalence of vitamin D deficiency is between 1.6–14.8% in different age groups [16-18]. In other European countries where there is no vitamin D supplementation, deficiency is more prevalent. The studies which assessed middle-aged and elderly people showed vitamin D deficiency prevalence of 14% to 59.6% in these age groups [19-22]. Vitamin D deficiency prevalence is much higher in Asian countries.

Fonseca and colleagues, demonstrated vitamin D level above 10 ng/ml in only 3 saudian females out of 31 [13]. Sedrani and colleagues showed vitamin D deficiency prev-
alence of 44%–100% in Saudian young females with different coverage and race [9,10]. Azizi & colleagues showed vitamin D level less than 18 ng/ml in half of the study population. Vitamin D deficiency prevalence in 10–19, 20–24, 30–41 was 47.4%, 59.5%, 44.8% respectively [11]. In the present study 81.3% of subjects had vitamin D deficiency.

Most studies have shown higher prevalence of vitamin D deficiency in the elderly [15-18]. Elderly females demonstrated statistically significant higher serum levels of vitamin D compared with young and middle aged females. Parenteral vitamin D intake by elderly was the major differentiating factor between various age groups that could explain high prevalence of a high level of vitamin D in elderly females.

Subjects who took vitamin D in the sampling period were excluded from the study, but those who had taken vitamin D in the preceding months were not omitted. Vitamin D has a long half-life and its frequent prescription especially in elderly women with musculo-skeletal complaints can explain differences in serum vitamin D. Regarding the essential role of sunlight in vitamin D synthesis, it is quite unexpected to see a high prevalence of vitamin D deficiency in countries such as Saudi Arabia. Different hypotheses can be made such as insufficient sun exposure, clothing habits, hyper pigmentation, air pollution, insufficient intake of vitamin D and special dietary habits [27]. Although sunlight plays an essential role in vitamin D synthesis, its role in vitamin D deficiency of Asians is not obvious. Tehran, which is located in 36° 21'' N, has a mean sun exposure of 8 hours per day [28].

In the present study sun exposure was not significantly different between subjects with vitamin D deficiency and those with normal vitamin D status.

Although there is sufficient sunlight in all seasons in Saudi Arabia, Sedrani showed that half of people who had more than 30 minutes of sun exposure had vitamin D less than 8 ng/ml (20 nmol/l) [10]. Holick & colleagues showed similar rate of vitamin D synthesis in Asians as of Europeans; but Asians required greater duration of exposure [29]. Other studies showed the same degree of increase in 25 (OH) D in summer months in Asians compared with Europeans [30]. In our study, there was no difference in clothing habits of vitamin D deficient group and normal group.

Sedrani showed 70% vitamin D deficiency in males compared with 30% in young females in spite of greater clothing in females [10].

Another hypothesis says that air pollution prevents enough UV exposure to skin. Insufficient vitamin D intake is another hypothesis for high prevalence of vitamin D deficiency in Asians.

Insufficient dietary supplies of vitamin D in countries where foodstuffs are not supplemented, leads to generally low dietary intake of vitamin D. In the Omdahl study,

**Table 2: Mean BMI and daily calcium intake in variable vitamin D groups**

| Groups     | Parameters | Vitamin D ≤ 12.5 (nmol/l) | 12.5<vitamin D ≤ 25 | 25<vitamin D ≤ 35 | 35.1<vitamin D ≤ 150 |
|------------|------------|--------------------------|---------------------|-------------------|----------------------|
| BMI (kg/m²) |            | 27.32 ± 5.02             | 26.44 ± 4.52        | 27.66 ± 5.16      | 26.99 ± 4.93         |
| Calcium intake (mg/day) |      | 503.39 ± 303.1*          | 577.93 ± 304.9*     | 595.84 ± 313.6*   | 714.67 ± 330.8*     |

*Significant difference with normal group (35.1<vitamin D ≤ 150) P < 0.05

Median, 5, and 95 percentile of Vitamin D in variable age and sex groups

---

Subjects who took vitamin D in the sampling period were excluded from the study, but those who had taken vitamin D in the preceding months were not omitted. Vitamin D has a long half-life and its frequent prescription especially in elderly women with musculo-skeletal complaints can explain differences in serum vitamin D. Regarding the essential role of sunlight in vitamin D synthesis, it is quite unexpected to see a high prevalence of vitamin D deficiency in countries such as Saudi Arabia. Different hypotheses can be made such as insufficient sun exposure, clothing habits, hyper pigmentation, air pollution, insufficient intake of vitamin D and special dietary habits [27]. Although sunlight plays an essential role in vitamin D synthesis, its role in vitamin D deficiency of Asians is not obvious. Tehran, which is located in 36° 21'' N, has a mean sun exposure of 8 hours per day [28].

In the present study sun exposure was not significantly different between subjects with vitamin D deficiency and those with normal vitamin D status.

Although there is sufficient sunlight in all seasons in Saudi Arabia, Sedrani showed that half of people who had more than 30 minutes of sun exposure had vitamin D less than 8 ng/ml (20 nmol/l) [10]. Holick & colleagues showed similar rate of vitamin D synthesis in Asians as of Europeans; but Asians required greater duration of exposure [29]. Other studies showed the same degree of increase in 25 (OH) D in summer months in Asians compared with Europeans [30]. In our study, there was no difference in clothing habits of vitamin D deficient group and normal group.

Sedrani showed 70% vitamin D deficiency in males compared with 30% in young females in spite of greater clothing in females [10].

Another hypothesis says that air pollution prevents enough UV exposure to skin. Insufficient vitamin D intake is another hypothesis for high prevalence of vitamin D deficiency in Asians.

Insufficient dietary supplies of vitamin D in countries where foodstuffs are not supplemented, leads to generally low dietary intake of vitamin D. In the Omdahl study,
daily vitamin D intake in elderly healthy women was 54 units [16]. Our study does not assess daily dietary vitamin D intake. Decreased dietary calcium level induces increased serum PTH level and increased catabolism of 25 (OH) D, therefore decreased 25(OH)D is induced by dietary calcium deficiency [15].

Average calcium intake was 660 ± 350 mg/day in this study. There was no significant difference in dietary calcium intake among the different vitamin D groups. Although consumption of phytates and animal-derived proteins was not investigated in present study, high dietary consumption of phytates and low dietary intake of animal proteins is one of the suggested hypothesis for vitamin D deficiency [24,26,27].

There are other hypotheses to explain vitamin D deficiency among Asians. Awumey et al showed higher activity level of 24-hydroxylase in fibroblasts of Indian-Americans compared with controls [31]. Therefore, increased vitamin D catabolism may cause vitamin D deficiency in Asians. In order to elucidate specific etiologies responsible for high prevalence of vitamin D deficiency in Asians further studies should be carried out. It is possible that vitamin D deficiency is induced by combination of above mentioned etiologies. In order to clarify the significance of each etiologic factor, randomized controlled trials are necessary.

Conclusions
Given the high prevalence of vitamin D deficiency in Iran, effective solution to overcome its consequences seems indispensable.
