Microscopic derivation of the Boltzmann equation for transport coefficients of resonating fermions at high temperature

Keisuke Fujii and Yusuke Nishida

Department of Physics, Tokyo Institute of Technology, Ookayama, Meguro, Tokyo 152-8551, Japan

(Dated: March 2021)

Motivated by the recently observed failure of the kinetic theory for the bulk viscosity, we in turn revisit the shear viscosity and the thermal conductivity of two-component fermions with a zero-range interaction both in two and three dimensions. In particular, we show that their Kubo formula evaluated exactly in the high-temperature limit to the lowest order in fugacity is reduced to the linearized Boltzmann equation. Previously, such a microscopic derivation of the latter was achieved only incompletely corresponding to the relaxation-time approximation. Here, we complete it by resuming all contributions that are naively higher orders in fugacity but become comparable in the zero-frequency limit due to the pinch singularity, leading to a self-consistent equation for a vertex function identical to the linearized Boltzmann equation. We then compute the shear viscosity and the thermal conductivity in the high-temperature limit for an arbitrary scattering length and find that the Prandtl number exhibits a nonmonotonic behavior slightly below the constant value in the relaxation-time approximation.

I. INTRODUCTION

The BCS-BEC crossover exhibited by two-component fermions with their scattering length varied has been subjected to comprehensive studies over the past two decades in ultracold-atom physics [1–4]. In particular, the system at infinite scattering length is referred to as the unitary Fermi gas and has been highlighted because of its strong correlation and scale invariance (nonrelativistic conformality [5–7]). These two unique aspects are both reflected not only in its universal thermodynamics but also in its transport properties.

Because the shear viscosity of a dilute gas tends to be small as the interaction is strengthened, its smallness serves as a measure of strong correlation. The shear viscosity of the unitary Fermi gas was measured experimentally [8–11] and found to be close to the conjectured quantum-mechanical lower bound [12]. On the other hand, the bulk viscosity of the unitary Fermi gas vanishes identically because of its conformality [13]. Therefore, the bulk viscosity serves as a measure of conformality breaking and its vanishment for the unitary Fermi gas was confirmed experimentally [14]. Experimental measurements of other transport coefficients have also been performed, such as the thermal conductivity [15] and the sound diffusivity [16] of the unitary Fermi gas, as well as the shear and bulk viscosities in two dimensions [17].

Theoretically, one common approach to compute the transport coefficients is the kinetic theory, which is founded on the quasiparticle approximation supposed to be applicable only in the weak-coupling or high-temperature limit [18–24]. As a matter of principle, the transport coefficients are to be microscopically computed with the Kubo formula. In spite of its difficulty in general situations, it can systematically be evaluated with the quantum virial expansion, which adopts the fugacity as a small expansion parameter in the high-temperature limit [25–29]. As a matter of principle, the transport coefficients are to be microscopically computed with the Kubo formula. In spite of its difficulty in general situations, it can systematically be evaluated with the quantum virial expansion, which adopts the fugacity as a small expansion parameter in the high-temperature limit [25–29].
function formalism was found to agree with that from the Boltzmann equation but only in the relaxation-time approximation [28,29]. Therefore, the complete correspondence between the microscopic and kinetic theories for the transport coefficients is yet to be established, which constitutes the main purpose of this paper.

To this end, we evaluate the Kubo formula for the shear viscosity and the thermal conductivity exactly in the high-temperature limit to the lowest order in fugacity. After describing general formulations in Sec. II, we sum up all contributions that are naively higher orders in fugacity but become comparable in the zero-frequency limit due to the pinch singularity [30–32]. Consequently, a self-consistent equation for a vertex function is derived in Sec. III which is shown to be identical to the linearized Boltzmann equation. Then, the linearized Boltzmann equation is solved numerically in Sec. IV to compute the Prandtl number in the high-temperature limit for an equation is solved numerically in Sec. IV to compute the shear viscosity and the thermal conductivity as well as the transport coefficients is yet to be established, which constitutes the main purpose of this paper.

In what follows, we will set \( h = k_B = 1 \) and implicit summations over repeated spin indices \( \sigma = \uparrow, \downarrow \) are assumed throughout this paper. The bosonic and fermionic frequencies in the Matsubara formalism are denoted by \( w = 2\pi n / \beta \) and \( v = 2\pi (n + 1/2) / \beta \), respectively, for \( n \in \mathbb{Z} \). Also, an integration over \( d \)-dimensional wave vector or momentum is denoted by \( \int_p \equiv \int dp / (2\pi)^d \) for the sake of brevity.

II. MICROSCOPICS

A. Hamiltonian

We consider two-component fermions with a zero-range interaction in \( d \) spatial dimensions described by

\[
\hat{H} = \int dr \left[ \frac{\Delta}{2m} - \mu \right] \hat{\psi}_\sigma^r(r) \hat{\psi}_\sigma^r(r) + \frac{g}{2} \int dr \hat{\psi}_\sigma^r(r) \hat{\psi}_\sigma^r(r)^\dagger \hat{\psi}_{\sigma'}^r(r) \hat{\psi}_{\sigma'}^r(r).
\]

(1)

We work with the Matsubara formalism and the bare fermion propagator in the Fourier space is denoted by

\[
G(iv, p) = \frac{1}{iv - \varepsilon_p + \mu}
\]

(2)

and the full fermion propagator by

\[
\hat{G}(iv, p) = \frac{1}{iv - \varepsilon_p + \mu - \Sigma(iv, p)};
\]

(3)

where \( \varepsilon_p = p^2 / (2m) \) is the energy of a single particle and \( \Sigma(iv, p) \) is the fermion self-energy.

FIG. 1. Diagrammatic representations of the pair propagator (top) and the fermion self-energy (bottom) in Eq. (4). The thin single and double lines represent the bare fermion and pair propagators, respectively, whereas the dot denotes a bare coupling constant.

In the high-temperature limit where the fugacity \( z = e^{\beta \mu} \sim N / T^{d/2} \ll 1 \) serves as a small expansion parameter [33], the fermion self-energy to its lowest order is evaluated as

\[
\Sigma(iv, p) = z \int_q e^{-\beta \varepsilon_q} D(iv + \varepsilon_q - \mu, p + q) + O(z^2),
\]

(4)

whose diagrammatic representation is depicted in Fig. 1. Here,

\[
D(iv, p) = \frac{\Omega_{d-1}}{m} \frac{d - 2}{a^{d-2}} [-m(iv - \varepsilon_p / 2 + 2\mu)]^{d/2 - 1}
\]

(5)

is the pair propagator in the vacuum, \( \Omega_{d-1} = (4\pi)^{d/2} / [2\Gamma(2 - d/2)] = 2, 2\pi, 4\pi \) coincides with the surface area of the unit \((d - 1)\)-sphere for \( d = 1, 2, 3 \), and the scattering length \( a \) is introduced via

\[
g = \frac{\Omega_{d-1}}{m} \frac{d - 2}{a^{d-2} - \Lambda^{d-2} / [\Gamma(d/2)\Gamma(2 - d/2)]}
\]

(6)

in the cutoff regularization [30].

For later use, we note that the above pair propagator is simply the two-body scattering \( T \)-matrix and the transition rate from initial \((p', q')\) to final momenta \((p, q)\) is provided by

\[
W(p, q | p', q') = |D(\varepsilon_p + \varepsilon_q - 2\mu + io^+, p + q)|^2 
\times (2\pi)^{d+1} \delta(\varepsilon_p + \varepsilon_q - \varepsilon_{p'} - \varepsilon_{q'}) \delta(p + q - p' - q').
\]

(7)

It is also related to the imaginary part of the pair propagator via the optical theorem:

\[
-2 \operatorname{Im}[D(\varepsilon_p + \varepsilon_q - 2\mu + io^+, p + q)] 
= \int_{p', q'} W(p, q | p', q').
\]

(8)
B. Kubo formula

According to the linear-response theory, the transport coefficients are microscopically provided by the Kubo formula [38][39],

$$\eta = \lim_{\omega \to 0} \frac{\text{Im}[\chi_{\Pi_{zz}}(\omega + i0^+)]}{\omega}$$  \hspace{1cm} (9)

for the shear viscosity and

$$T \kappa = \lim_{\omega \to 0} \frac{\text{Im}[\chi_{O}(\omega + i0^+)]}{\omega}$$  \hspace{1cm} (10)

for the thermal conductivity [38][40]. Here, \(\chi_{\hat{O}}(\omega + i0^+)\) is a retarded correlation function at zero wave vector for an operator \(\hat{O}\), which is most conveniently obtained from the corresponding imaginary-time-ordered correlation function,

$$\chi_{\hat{O}}(iw) = \frac{1}{L^d} \int_0^\beta d\tau e^{i\omega \tau} \langle \hat{O}(\tau)\hat{O}(0) \rangle$$  \hspace{1cm} (11)

with an analytic continuation of \(iw \to \omega + i0^+\) [41].

For our system described by Eq. (1), the off-diagonal stress tensor operator is found to be

$$\hat{\Pi}_{ij} = \int dr \left[ \frac{\Delta \hat{\psi}_\sigma^\dagger(r) \partial_i \hat{\psi}_\sigma(r) - \partial_j \hat{\psi}_\sigma^\dagger(r) \Delta \hat{\psi}_\sigma(r)}{4im^2} (i \neq j) \right. \hspace{1cm} (12)$$

and the heat flux operator to be

$$\hat{\dot{Q}}_i = \int dr \left[ -\frac{\Delta \hat{\psi}_\sigma^\dagger(r) \partial_i \hat{\psi}_\sigma(r)}{2im} - \frac{\mathcal{E} + \mathcal{P}}{N} \frac{\hat{\psi}_\sigma^\dagger(r) \partial_i \hat{\psi}_\sigma(r) - \partial_i \hat{\psi}_\sigma^\dagger(r) \hat{\psi}_\sigma(r)}{2im} \right. \hspace{1cm} (13)$$

where \(N\), \(\mathcal{E}\), and \(\mathcal{P}\) are the number density, the energy density, and the pressure, respectively [42][43]. Whereas the off-diagonal stress tensor operator is simply a one-body operator, the heat flux operator consists of both one-body and two-body operators. As we will see later, contributions of the one-body operator to the transport coefficient are partly promoted from \(O(z)\) to \(O(z^0)\) due to the pinch singularity, but the two-body operator is supposed to provide higher-order corrections at \(O(z^2)\). Therefore, as far as the transport coefficient to the lowest order in fugacity is concerned, it is sufficient to consider only the one-body operator in the form of

$$\hat{O} = \sum_p \gamma_p \hat{\psi}_\sigma^\dagger \hat{\psi}_{\sigma p};$$  \hspace{1cm} (14)

where \(\hat{\psi}_{\sigma p} = L^{-d/2} \int dr e^{-ip \cdot r} \hat{\psi}_\sigma(r)\) is a Fourier component of the field operator. Obviously, the bare vertex function reads \(\chi_{\hat{O}} = p_x p_y / m\) for the shear viscosity and \(\chi_{\hat{O}} = [\mathcal{E} - (\mathcal{E} + \mathcal{P})/N]/p_e / m\) for the thermal conductivity and the corresponding transport coefficients are collectively denoted by

$$\sigma_{\sigma} \equiv \lim_{\omega \to 0} \frac{\text{Im}[\chi_{\hat{O}}(\omega + i0^+)]}{\omega}.$$  \hspace{1cm} (15)

Here, it is worthwhile to remark that \(\hat{O} \sim (mg)^2 \int dr e^{-ip \cdot r} \hat{\psi}_\sigma(r)\) is a Fourier component of the field operator. Obviously, the bare vertex function reads \(\chi_{\hat{O}} = p_x p_y / m\) for the shear viscosity and \(\chi_{\hat{O}} = [\mathcal{E} - (\mathcal{E} + \mathcal{P})/N]/p_e / m\) for the thermal conductivity and the corresponding transport coefficients are collectively denoted by

$$\sigma_{\sigma} \equiv \lim_{\omega \to 0} \frac{\text{Im}[\chi_{\hat{O}}(\omega + i0^+)]}{\omega}.$$  \hspace{1cm} (15)

C. Pinch singularity

For the one-body operator in the form of Eq. (14), the imaginary-time-ordered correlation function in Eq. (11) can formally be expressed as

$$\chi_{\hat{O}}(iw) = -\frac{2}{\beta} \sum_p \int_{\nu} \gamma_p \mathcal{G}(i\nu + iw, p) \mathcal{G}(i\nu, p) \times \Gamma(i\nu + iw, i\nu; p),$$  \hspace{1cm} (16)

whose diagrammatic representation is depicted in Fig. 2. Here, the spin degeneracy accounts for the prefactor of 2 and \(\Gamma(i\nu + iw, i\nu; p)\) is the full vertex function to be determined in Sec. II.A.

In order to achieve the analytic continuation to obtain the retarded correlation function, it is sufficient to know that \(\mathcal{G}(\nu, p)\) and \(\Gamma(i\nu + iw, i\nu; p)\) may have singularities only along \(\text{Im}(\nu) = 0\) and \(\text{Im}(\nu) = 0, -w\), respectively, in the complex plane of \(\nu\) [31] (see also Appendix A). With the Matsubara frequency summation replaced by the complex contour integration over \(iv \to \nu\), its contour is deformed into four horizontal lines as in Fig. 3 leading to
counting breaks down in the zero-frequency limit, \( \omega \rightarrow 0 \) and advanced \( \pi \delta(\nu - \varepsilon_p + \mu) + O(z) \) in the high-temperature limit, we find that

\[
G_+(\nu, p)G_-(\nu, p) = -\frac{\pi \delta(\nu - \varepsilon_p + \mu)}{\text{Im}[\Sigma(\varepsilon_p - \mu + i0^+, p)]} + O(z^0)
\]

is inversely proportional to the fugacity so as to promote its order by one. Therefore, the resulting transport coefficient in Eq. (15) actually involves an \( O(z^0) \) contribution provided by

\[
\sigma_0 = 2\beta \int_p \frac{e^{-\beta\varepsilon_p}\gamma_p}{2\text{Im}[\Sigma_+(p)]} + O(z).
\]

Here, shorthand notations for on-shell \( \Sigma_+(p) \equiv \Sigma(\varepsilon_p - \mu + i0^+, p) \) and \( \Gamma_+(p) \equiv \Gamma(\varepsilon_p - \mu + i0^+, \varepsilon_p - \mu - i0^+: p) \) are introduced. We note that the latter is real and the former has both real and imaginary parts at \( O(z) \) according to Eq. (1).

An important lesson to be learned is as follows: The correlation function in Fig. 2 is naively \( O(z) \) as also seen diagrammatically because there exists one fermion propagator running backward in imaginary time \([27, 44]\). However, the product of two fermion propagators with the same frequency and wave vector, such as the two thick lines in Fig. 2, produces an inverse power of the fugacity so as to promote its order by one compared to the naive counting. This is the so-called pinch singularity \([31-34]\), which needs to be taken into account in order to compute the static transport coefficient correctly to the lowest order in fugacity.

### III. TOWARD THE KINETIC THEORY

#### A. Vertex function

Our remaining task is to determine the full vertex function to the lowest order in fugacity. If the naive expansion with respect to the fugacity is applied at nonzero frequency, its leading term is simply the bare vertex function and the next-to-leading-order corrections at \( O(z) \) are provided by two types of diagrams called Maki-Thompson and Aslamazov-Larkin \([25, 27]\). The result-

\[2\] The self-energy diagrams are already taken into account by adopting the full fermion propagator in Eq. (16).
The diagrammatic representation of such a naive expansion is depicted in Fig. 5 (top), where the second term of Eq. (22) by the full one, leading to
\[
\Gamma (iv + iw, iv; p) = \gamma_p + \frac{1}{\beta} \sum_{v'} \int_{p'} K(iv + iw, iv; p|iv' + iw, iv'; p')
\times G(iv' + iw, p')G(iv', p')\gamma_{p'} + O(z^{2}),
\] (22)

where \( K(*) = K_{MT}(*) + K_{AL}(*) \) is the four-point function depicted in Fig. 4 consisting of
\[
K_{MT}(iv + iw, iv; p|iv' + iw, iv'; p') = D(iv + iv' + iw, p + p')
\] (23)
and
\[
K_{AL}(iv + iw, iv; p|iv' + iw, iv'; p') = -\frac{2}{\beta} \sum_{iv''} \int_{p''} D(iiw'' + iw, p'')D(iiw'', p'')
\times G(iiw'' - iv, p'' - p')G(iiw'' - iv', p'' - p').
\] (24)

The diagrammatic representation of such a naive expansion is depicted in Fig. 5 (top), where the second term is seen to be \( O(z^{2}) \) because each diagram therein can be organized so that there exists one fermion propagator running backward in imaginary time \([21]\).

As learned in Sec. II C, the above naive expansion breaks down in the zero-frequency limit. This is because the second term of Eq. (22) involves the product of two fermion propagators with the same frequency and vector wave. With the bare fermion propagators therein replaced by the full ones, the pinch singularity produces \( z/\text{Im}\Sigma \sim O(z^{0}) \) comparable to the first term. Furthermore, an iteration of the same diagrammatic structure for \( n \) times also contributes \( (z/\text{Im}\Sigma)^{n} \sim O(z^{0}) \), so that an infinite sequence of such comparable diagrams needs to be resummed\(^3\). Such a resummation can formally be achieved by replacing the bare vertex function in the second term of Eq. (22) by the full one, leading to
\[
\Gamma (iv + iw, iv; p) = \gamma_p + \frac{1}{\beta} \sum_{v'} \int_{p'} K(iv + iw, iv; p|iv' + iw, iv'; p')
\times G(iv' + iw, p')G(iv', p')\Gamma (iv' + iw, iv'; p').
\] (25)

This is the closed integral equation that self-consistently determines the vertex function to the lowest order in fugacity and its diagrammatic representation is depicted in Fig. 5 (bottom).

B. Analytic continuation

1. Maki-Thompson

We now evaluate the above self-consistent equation for the vertex function so that it can be analytically continued into that for \( \Gamma_{(+)} (p) \) needed to compute the transport coefficient according to Eq. (21). Let us start with the Maki-Thompson part denoted by
\[
\Gamma_{MT}(iv + iw, iv; p) \equiv \frac{1}{\beta} \sum_{v'} \int_{p'} K_{MT}(iv + iw, iv; p|iv' + iw, iv'; p')
\times G(iv' + iw, p')G(iv', p')\Gamma (iv' + iw, iv'; p'),
\] (26)

where the four-point function is provided by Eq. (23). With the Matsubara frequency summation replaced by the complex contour integration over \( iv' \rightarrow v' \), the integrand may have singularities only along \( \text{Im}(v') = 0, -w, -v - w \) in the complex plane of \( v' \). Therefore, its contour is deformed into six horizontal lines in a similar way to Fig. 3. Because only two of them along

\[+\]

3 Previously, the resummation was performed only approximately assuming a simple geometric series based on the lowest two terms in fugacity \([24,27]\), which turns out to correspond to the relaxation-time approximation (see Appendix B).
Im(ν′) = −0⁺, −w + 0⁺ turn out to contribute \( O(z^0) \) in the zero-frequency limit, we obtain

\[
\Gamma_{MT}(iv + iw, iv; p) = \int_{-\infty}^{\infty} \frac{dv'}{2\pi i} f_p(v') \int_{p'} \times D(v' + iv + iw; p + p')G(v' + iv + iw; p') \\
\times G(v' - i0^+, p')\Gamma(v' + iw, ν' - i0^+; p') \\
- D(v' + iv, p + p')G(v' + i0^+, p') \\
\times G(v' - iw, p')\Gamma(v' + i0^+, ν' - iw; p') + O(z),
\]

(27)

Then, the analytic continuation of \( iv \to ε_p - μ - i0^+ \) followed by \( iv \to i0^+ \) leads to

\[
\Gamma_{MT}(ε_p - μ + i0^+, ε_p - μ - i0^+; p) \\
= - \int_{q,p',q'} e^{-βε_p} W(p, q | p', q') \frac{z G_{+\nu}(q)}{-2 \text{Im}[Σ_+(q)\Gamma(2)]} + O(z),
\]

(28)

where the pinch singularity in Eq. (20) is applied as well as Eq. (3) with some change of the integration variable.

2. Aslamazov-Larkin

We next turn to the Aslamazov-Larkin part denoted by

\[
\Gamma_{AL}(iv + iw, iv; p) \\
≡ \frac{1}{β} \sum_\nu \int_{p'} K_{AL}(iv + iw, iv; p | iv' + iw, iv'; p') \\
\times G(iv' + iw, p')G(iv'; p')\Gamma(iv' + iw, iv'; p').
\]

(29)

Here, the four-point function in Eq. (24) is evaluated to the lowest order in fugacity as

\[
K_{AL}(iv + iw, iv; p | iv' + iw, iv'; p') \\
= -2z \int_{p''} e^{-βε_p} D(iv + iw + εp'' - p - μ, p'') \\
\times D(iv + εp'' - p - μ, p'') \\
- 2z \int_{p''} e^{-βε_p} D(iv' + iw + εp'' - p - μ, p'') \\
\times D(iv' + εp'' - p - μ, p'') + O(z^2),
\]

(30)

which is dominated by the contributions from the poles of the fermion propagators because the branch cuts of the pair propagators contribute \( O(z^2) \).

With the Matsubara frequency summation replaced by the complex contour integration over \( iv' \to ν' \), the integrand may have singularities only along \( \text{Im}(ν') = 0, -w \) in addition to a pole at \( ν' = iv + εp'' - p - εp'' - p' \) in the complex plane of \( ν' \). Therefore, its contour is deformed into four horizontal lines as in Fig. 3 and one clockwise circle around the pole. Because only the latter turns out to contribute \( O(z^0) \) in the zero-frequency limit, we obtain

\[
\Gamma_{AL}(iv + iw, iv; p) = 2z \int_{p'} e^{-βε_p} W(p, q | p', q') \frac{z G_{+\nu}(q)}{-2 \text{Im}[Σ_+(q)\Gamma(2)]} + O(z),
\]

(31)

Then, the analytic continuation of \( iv \to ε_p - μ - i0^+ \) followed by \( iv \to i0^+ \) leads to

\[
\Gamma_{AL}(ε_p - μ + i0^+, ε_p - μ - i0^+; p) \\
= 2 \int_{q,p',q'} e^{-βε_p} W(p, q | p', q') \frac{z G_{+\nu}(p')}{-2 \text{Im}[Σ_+(p')\Gamma(2)]} + O(z),
\]

(32)

where the pinch singularity in Eq. (20) is applied as well as Eq. (3) with some change of the integration variable.

3. C. On-shell self-consistent equation

With Eqs. (28) and (32) substituted, Eq. (25) is analytically continued into

\[
\Gamma_{+\nu}(p) = γ_p - \int_{q,p',q'} e^{-βε_p} W(p, q | p', q') \\
\times \left\{ \frac{z G_{+\nu}(q)}{-2 \text{Im}[Σ_+(q)\Gamma(2)]} - \frac{z G_{+\nu}(p')}{-2 \text{Im}[Σ_+(p')\Gamma(2)]} \right\} + O(z),
\]

(33)

which is now the closed integral equation for the on-shell vertex function to the lowest order in fugacity.

In order to show that the resulting on-shell self-consistent equation is identical to the linearized Boltzmann equation (32) (34), we introduce

\[
φ(p) = \frac{z G_{+\nu}(p)}{-2 \text{Im}[Σ_+(p)\Gamma(2)]},
\]

(34)

so that Eq. (33) turns into

\[
γ_p = \frac{-2 \text{Im}[Σ_+(p)\Gamma(2)]}{z} φ(p) + \int_{q,p',q'} e^{-βε_p} W(p, q | p', q') \\
\times [φ(q) - 2φ(p') + O(z)].
\]

(35)

Because of \( W(p, q | p', q') = W(p, q | p', q') \) and

\[
-2 \text{Im}[Σ_+(p)] = z \int_{q,p',q'} e^{-βε_p} W(p, q | p', q') + O(z^2)
\]

(36)

according to Eqs. (7), (8), and (4), we indeed find that

\[
γ_p = \int_{q,p',q'} e^{-βε_p} W(p, q | p', q') \\
\times [φ(p) + φ(q) - φ(p') - φ(q')] + O(z)
\]

(37)
is none other than the linearized Boltzmann equation \[45\] (see also Appendix [3]).

Once the solution of \(\varphi(p)\) for a given \(\gamma_p\) is determined, the corresponding transport coefficient in Eq. (21) is provided by

\[
\sigma_\beta = 2\beta \int_p e^{-\beta \varepsilon_p \gamma_p} \varphi(p) + O(z).
\] (38)

Therefore, it is hereby established that computing the shear viscosity and the thermal conductivity in the high-temperature limit to the lowest order in fugacity is reduced to the kinetic theory, which contrasts with the bulk viscosity and constitutes the main outcome of this paper.

### IV. TRANSPORT COEFFICIENTS

Finally, we solve the linearized Boltzmann equation in Eq. (37) to compute the transport coefficients according to Eq. (38) both in two and three dimensions. To this end, we expand \(\varphi(p)\) in terms of the generalized Laguerre polynomials,

\[
\varphi(p) = \beta \frac{p_x p_y}{m} \sum_{n=0}^{N-1} c_n L_n^{d/2+1}(\beta \varepsilon_p) \tag{39}
\]

for the shear viscosity with \(\gamma_p = p_x p_y / m\) and

\[
\varphi(p) = \frac{p_x}{m} \sum_{n=1}^N c_n L_n^{d/2}(\beta \varepsilon_p) \tag{40}
\]

for the thermal conductivity with \(\gamma_p = [\varepsilon_p - (\mathcal{E} + \mathcal{P})/N] p_x / m\) \[45\]. We note that \(N = 2z/\lambda_T^2 + O(z^2), \mathcal{E} = (d/2) N/\beta + O(z^2), \) and \(\mathcal{P} = N/\beta + O(z^2)\) in the high-temperature limit, where \(\lambda_T = \sqrt{2\pi \beta / m}\) is the thermal de Broglie wavelength \[26\]. If the above expansion is truncated up to the lowest \(N\) terms, the simplest case of \(N = 1\) corresponds to the relaxation-time approximation to be described in Appendix B.3.

Here, \(N\) is increased up to \(N = 10\), which is confirmed to be more than sufficient for convergence of the presented results, and the resulting shear viscosity and thermal conductivity for \(d = 2\) and \(d = 3\) are plotted in Fig. 6 as functions of the inverse scattering length. They are exact in the high-temperature limit to the lowest order in fugacity and found to be slightly larger than those obtained with the relaxation-time approximation up to 2.5% deviations. In particular, we find that the shear viscosity and the thermal conductivity for \(d = 2\) reach their minima of \(\lambda_T^2 \eta = 3.257\) at \(\lambda_T / a = 4.019\) and \(\lambda_T^3 m \kappa = 13.03\) at \(\lambda_T / a = 4.017\), respectively, and our thermal conductivity in two dimensions is new to the best of our knowledge. We also find \(\lambda_T^2 \eta = 4.231\) and \(\lambda_T^3 m \kappa = 16.01\) for \(d = 3\) at infinite scattering length, \(\lambda_T / a = 0\), where the relaxation-time approximation produces \(\lambda_T^2 \eta = 15\pi/(8\sqrt{2}) \approx 4.165\) \[18\] \[19\] and \(\lambda_T^3 m \kappa = 225\pi/(32\sqrt{2}) \approx 15.62\) \[20\], respectively.

Our exact results for the shear viscosity and the thermal conductivity allow us to study the Prandtl number defined by their ratio via

\[
\Pr \equiv \frac{\eta}{m \kappa} c_p. \tag{41}
\]

Here, the heat capacity at constant pressure per particle is provided by \(c_p = (d + 2)/2 + O(z)\) in the high-temperature limit \[20\]. The resulting Prandtl number for \(d = 2\) and \(d = 3\) is plotted in Fig. 7 as a function of the inverse scattering length. Remarkably, it is found to exhibit the nonmonotonic behavior slightly be-

---

4 There exists no solution to Eq. (37) for \(d = 1\) because its right-hand side vanishes identically due to the energy and momentum conservations.

5 The \(n = 0\) term in Eq. (40) is not needed because it vanishes when substituted into Eq. (37) due to the momentum conservation. This is also consistent with the Chapman-Enskog condition in Eq. (45) from the kinetic theory perspective.
low the constant value of $Pr = (d-1)/d$ in the relaxation-time approximation. In particular, it reaches its two minima of $Pr = 0.4986$ and $0.4985$ at $\lambda_T/a = 0.6948$ and $20.45$, respectively, for $d = 2$ and its maximum of $Pr = 0.5000$ at $\lambda_T/a = 3.871$ for $d = 2$ and $Pr = 0.6666$ at $\lambda_T/a = \pm 4.262$ for $d = 3$. We also find that the minimum of $Pr = 0.6606$ is reached at infinite scattering length, $\lambda_T/a = 0$, for $d = 3$.

V. SUMMARY

In this paper, we evaluated the Kubo formula [Eq. (15)] for the shear viscosity and the thermal conductivity exactly in the high-temperature limit to the lowest order in fugacity and showed that it is reduced to the linearized Boltzmann equation [Eqs. (37) and (38)]. This task was achieved by resuming all contributions that are naively higher orders in fugacity but become comparable in the zero-frequency limit due to the pinch singularity [Eq. (20)]. Consequently, the complete correspondence between the microscopic and kinetic theories for the transport coefficients is now established beyond the previous relaxation-time approximation. The bulk viscosity is however the exception because its corresponding operator in the Kubo formula is essentially a two-body operator without the one-body part in the form of Eq. (14). We also found by solving the linearized Boltzmann equation numerically for an arbitrary scattering length that the Prandtl number in the high-temperature limit exhibits the nonmonotonic behavior slightly below the constant value in the relaxation-time approximation both in two and three dimensions (Fig. 7).

Here, we worked with the Matsubara formalism to take advantage of the established quantum virial expansion, which however requires the cumbersome analytic conti-

uation [31]. Instead, it will also be worthwhile to adopt the Keldysh formalism, where it is possible to directly identify diagrams with the pinch singularity and formulate the systematic expansion incorporating higher-order corrections [34]. Developing the quantum virial expansion in the Keldysh formalism may provide us with a useful theoretical framework to study broad nonequilibrium phenomena in ultracold-atom physics.

Appendix A: Spectral representation of three-point functions

Let us review the spectral representation of three-point functions in the form of

$$J(\tau_1, \tau_2, \tau_3) = \langle T \psi^\dagger(\tau_1)\psi(\tau_2)O(\tau_3) \rangle,$$  \hfill (A1)

which is relevant to the full vertex function introduced in Eq. (16). Here, its spin indices and spatial coordinates are suppressed for the sake of brevity and this section is partly based on Ref. [31] (see Appendix therein).

The above imaginary-time-ordered product consists of six terms corresponding to different orderings of three imaginary times and it will turn out to be convenient to group them into two cycles as

$$J(\tau_1, \tau_2, \tau_3) = J_{123}(\tau_1, \tau_2, \tau_3) + J_{213}(\tau_1, \tau_2, \tau_3), \hfill (A2)$$

where

$$J_{123}(\tau_1, \tau_2, \tau_3) \equiv J(\tau_1, \tau_2, \tau_3)[\Theta(\tau_1, \tau_2, \tau_3) + \Theta(\tau_2, \tau_3, \tau_1) + \Theta(\tau_3, \tau_1, \tau_2)] \hfill (A3)$$

and

$$J_{213}(\tau_1, \tau_2, \tau_3) \equiv J(\tau_1, \tau_2, \tau_3)[\Theta(\tau_2, \tau_1, \tau_3) + \Theta(\tau_1, \tau_3, \tau_2) + \Theta(\tau_3, \tau_2, \tau_1)] \hfill (A4)$$

with $\Theta(\tau_1, \tau_2, \tau_3) \equiv \theta(\tau_1 - \tau_2)\theta(\tau_3 - \tau_2)$ being a step function of three variables. By inserting identity operators composed of the Hamiltonian eigenstates, $J_{123}(\tau_1, \tau_2, \tau_3)$ can be expressed as

$$J_{123}(\tau_1, \tau_2, \tau_3) = \frac{1}{Z} \sum_{l,m,n} \mathcal{J}_{lmn}$$

$$\times e^{-\beta E_l(\tau_3 - \tau_1) - E_m(\tau_1 - \tau_2) - E_n(\tau_2 - \tau_3)} [e^{-\beta E_l(\tau_3 - \tau_1)}[\Theta(\tau_1, \tau_2, \tau_3)]$$

$$- e^{-\beta E_m} \Theta(\tau_2, \tau_3, \tau_1) + e^{-\beta E_n} \Theta(\tau_3, \tau_1, \tau_2)], \hfill (A5)$$
where $J_{lmn}$ is a product of three matrix elements. A similar expression is obtained for $J_{213}(\tau_1, \tau_2, \tau_3)$ by exchanging $\psi^\dagger \leftrightarrow \psi$ in $-J_{123}(\tau_2, \tau_1, \tau_3)$.

Then, we would like to evaluate its Fourier component provided by

$$J_{123}(iv, iv', iw) = \int_0^\beta dr_3 \int_0^\beta dr_2 \int_0^\beta dr_1 e^{-i\nu_1 + iv'r_1 - iw_3} \times J_{123}(\tau_1, \tau_2, \tau_3).$$

(A6)

This computation is facilitated by changing the integration variables to $\tau_1 \equiv \tau_1 - \tau_2, \tau_2 \equiv \tau_2 - \tau_3, \text{ and } \tau_3$, so that the intervals of integration turn into $\int_0^\beta dr_3 \int_0^\beta dr_2 \int_0^\beta dr_1 e^{-i\nu_1 + iv'r_1 - iw_3}$.

Because of the periodicity of the integrand with respect to $\tau_1$ and $\tau_2$ by $\beta$, the integration can be performed instead on the intervals of $\int_0^\beta dr_3 \int_0^\beta dr_2 \int_0^\beta dr_1$ assuming the vanishing integrand for $\tau_1 + \tau_2 > \beta$. Therefore, we find

$$J_{123}(iv, iv', iw) = \frac{1}{\beta} \sum l,m,n J_{lmn} \int_0^\beta dr_3 \int_0^\beta dr_2 \int_0^\beta dr_1 e^{-i\nu_1 + iv'r_1 - iw_3} \times \epsilon(E_l - E_m) \tau_{12}.$$

(A7)

which readily leads to

$$J_{123}(iv, iv', iw) = \frac{1}{\beta} \sum l,m,n J_{lmn} \beta \delta_{iv', iv+\nu} \epsilon(E_l - E_m)$$

$$\times \left[ \frac{e^{-\beta E_l} e^{-\beta E_m}}{\epsilon(E_l + E_m)} \right]$$

$$+ \left[ \frac{e^{-\beta E_l} e^{-\beta E_m}}{\epsilon(E_l + E_m)} \right]$$

$$- \left[ \frac{e^{-\beta E_l} e^{-\beta E_m}}{\epsilon(E_l + E_m)} \right].$$

(A8)

A similar expression is obtained for the Fourier component of $J_{123}(\tau_1, \tau_2, \tau_3)$ by exchanging $\psi^\dagger \leftrightarrow \psi$ in $-J_{123}(-iv', -iv, iw)$, so that the Fourier component of $J(\tau_1, \tau_2, \tau_3)$ reads

$$J(iv, iv', iw) = J_{123}(iv, iv', iw)$$

$$- \frac{J_{123}(-iv', -iv, iw)}{\psi^\dagger \leftrightarrow \psi}.$$

(A9)

Because $J(iv, iv', iw)$ is found to be proportional to $\delta_{iv', iv+\nu}$, a function of two independent variables can be introduced via $J(iv, iv', iw) = \beta \delta_{iv', iv} J(iv, iv + iw)$. It is now obvious from the above spectral representation that $J(iv, iv', iw)$ may have singularities only along $\Im(\nu) = 0, -\nu$ in the complex plane of $\nu$. In particular, the same is true for the full vertex function, $\Gamma(\nu + iw, \nu; p)$, because $J(iv, iv + iw)$ is reduced to $\mathcal{G}(iv + iw, p)\mathcal{G}(iv, p)\Gamma(iv + iw, iv; p)$ in Eq. (A3) as a special case.

Appendix B: Boltzmann equation for transport coefficients

Let us review computations of the transport coefficients with the classical Boltzmann equation [13]:

$$\frac{\partial f_p}{\partial t} + \frac{\partial f_p}{\partial p} \cdot \frac{\partial f_p}{\partial r} = \left( \frac{\partial f_p}{\partial t} \right)_{\text{coll}}.$$

(B1)

Here, $f_p = f_p(t, r)$ is a local distribution function per spin and the collision term is provided by

$$\left( \frac{\partial f_p}{\partial t} \right)_{\text{coll}} = \int_{q, p' q} W(p, q|p', q') f_p f_q' - f_p f_q.$$

(B2)

with the transition rate satisfying $W(p, q|p', q') = W(q, p|p', q') = W(p', q'|p, q) = W(p + mv, q + mv|p' + mv, q' + mv)$ and being proportional to $(2\pi)^{d+1} |\nu + \nu_0 - \nu rt - \nu_0 - \nu r|^2 \delta(p + q - p' - q').$

1. Linearization

When the system is slightly out of thermodynamic equilibrium, the distribution function is expanded as $f_p = \tilde{f}_p + \delta f_p$, where

$$\tilde{f}_p = \exp\left\{ -\beta \left[ \frac{(p - m\nu)^2}{2m} - \mu \right] \right\}$$

(B3)

is a local equilibrium distribution function. Because the local chemical potential $\mu = \mu(t, r)$, velocity $\nu = \nu(t, r)$, and inverse temperature $\beta = \beta(t, r)$ are determined so that $\tilde{f}_p$ solely produces local number, momentum, and energy densities, $\delta f_p$ satisfies the Chapman-Enskog condition of

$$\int_p \delta f_p = \int_p \delta f_p = \int_p \tilde{f}_p = 0.$$

(B4)

In what follows, implicit summations over repeated spatial indices $i = 1, 2, \ldots, d$ are assumed.

The substitution of $f_p = \tilde{f}_p + \delta f_p$ into the left-hand side (LHS) of Eq. (B3) with the help of thermodynamic relations and continuity equations leads to

$$(LHS) = \beta \tilde{f}_p \left[ \pi_{ij}(p + mw) V_{ij} + \pi(p - m\nu) V \right.$$

$$- \mathcal{Q}(p - m\nu) \cdot \nabla \ln \beta] + O(\delta f).$$

(B5)

Here, the shear and bulk strain rates are denoted by

$$V_{ij} = \partial_i v_j + \partial_j v_i - \frac{2}{d} \delta_{ij} \nabla \cdot \nu$$

(B6)

and $V = \nabla \cdot v$, respectively, whereas

$$\pi_{ij}(p) = \frac{p_i p_j}{m} - \frac{p^2}{dm} \delta_{ij}.$$

(B7)
is the traceless part of the stress tensor,
\[ \pi(p) = \frac{P^2}{dm} \left( \frac{\partial P}{\partial N} \right)_s - \varepsilon_p \left( \frac{\partial P}{\partial \varepsilon} \right)_N \]  \hspace{1cm} \text{(B8)}
its modified diagonal part, and
\[ \mathcal{Q}(p) = \left( \varepsilon_p - \frac{\mathcal{E}}{m} \right) \frac{p}{m} \]  \hspace{1cm} \text{(B9)}
the heat flux of a single particle. We note that \( \pi(p) = 0 \) because of \( P = (2/d) \mathcal{E} = N/\beta \), indicating the vanishing bulk viscosity within the Boltzmann equation \[22,24\].

On the other hand, the substitution of \( f_p = f_p + \delta f_p \) into the right-hand side (RHS) of Eq. (B1) with \( \delta f_p \equiv \beta f_p \phi_p \) introduced leads to
\[
\text{(RHS)} = \beta f_p \int_{q,q'} q W(p,q|p',q') \times (\phi_p + \phi_{q'} - \phi_p - \phi_q) + O(\delta f^2) \]  \hspace{1cm} \text{(B10)}
because the equilibrium distribution function cancels the collision term. In order for the resulting expression to match the left-hand side in Eq. (B5) for arbitrary \( \mu, v \), and \( \beta, \phi_p \) must be in the form of
\[
\phi_p = -e^{-\beta \mu} \left[ \varphi_{ij}(p - mv) \frac{V_{ij}}{2} - \varphi(p - mv) \cdot \nabla \ln \beta \right]. \]  \hspace{1cm} \text{(B11)}
Here, \( \varphi_{ij}(p) \) and \( \varphi(p) \) determine the deviations from the equilibrium distribution function induced by the shear strain rate and the temperature gradient, respectively, which solve
\[
\pi_{xy}(p) = \int_{q,p',q'} e^{-\beta \varepsilon_q} W(p,q|p',q') \times [\varphi_{xy}(p) + \varphi_{xy}(q) - \varphi_{xy}(p') - \varphi_{xy}(q')] \]  \hspace{1cm} \text{(B12a)}
and
\[
\mathcal{Q}_x(p) = \int_{q,q'} e^{-\beta \varepsilon_q} W(p,q|p',q') \times [\varphi_x(p) + \varphi_x(q) - \varphi_x(p') - \varphi_x(q')] \]  \hspace{1cm} \text{(B12b)}
This is the linearized Boltzmann equation identical to Eq. (37) derived microscopically from the Kubo formula.

2. Transport coefficients

The stress tensor and the energy flux in the kinetic theory are provided by
\[
\Pi_{ij} = 2 \int \frac{p_i p_j}{m} f_p, \]  \hspace{1cm} \text{(B13)}
\[ \mathcal{K} = 2 \int \frac{\varepsilon_p P}{m} f_p \]  \hspace{1cm} \text{(B14)}
respectively, where the spin degeneracy accounts for the prefactor of 2. The substitution of \( f_p = f_p + \delta f_p \) with Eq. (B1) imposed decomposes the former into \( \Pi_{ij} = \mathcal{P} \delta_{ij} + mN v_i v_j - \sigma_{ij} \) with the dissipative correction of
\[
\sigma_{ij} = -2\beta \int \frac{f_p}{p} \pi_{ij}(p - mv) \phi_p, \]  \hspace{1cm} \text{(B15)}
whereas the latter is decomposed into \( \mathcal{K} = (\mathcal{E} + \varepsilon_{mv} N + \mathcal{P}) v_i - \sigma_{ij} v_j + k_i \) with
\[
k = -\kappa \nabla T, \]  \hspace{1cm} \text{(B16)}
By substituting Eq. (B11) and comparing the resulting expressions to the corresponding ones in hydrodynamics,
\[
\sigma_{ij} = \eta V_{ij} + \zeta \delta_{ij} V, \]  \hspace{1cm} \text{(B17)}
\[ \kappa = -\kappa \nabla T, \]  \hspace{1cm} \text{(B18)}
we find \( \zeta = 0 \) for the bulk viscosity and
\[
\eta = 2\beta \int e^{-\beta \varepsilon_p} \pi_{xy}(p) \varphi_{xy}(p), \]  \hspace{1cm} \text{(B19a)}
\[ T\kappa = 2\beta \int e^{-\beta \varepsilon_p} \mathcal{Q}_x(p) \varphi_x(p), \]  \hspace{1cm} \text{(B19b)}
which are identical to Eq. (38) for the shear viscosity and the thermal conductivity.

3. Relaxation-time approximation

Whereas the linearized Boltzmann equation was solved numerically in Sec. [IV], it is also common to solve it with the so-called relaxation-time approximation \[18,22\], which assumes simple proportional relations in the form of
\[
\varphi_{xy}(p) = z \tau_\eta \pi_{xy}(p), \]  \hspace{1cm} \text{(B20a)}
\[ \varphi_x(p) = z \tau_\kappa \mathcal{Q}_x(p). \]  \hspace{1cm} \text{(B20b)}
Here, \( \tau_\eta \) and \( \tau_\kappa \) are the shear and thermal relaxation times, respectively, which are determined by substituting the above relations into the linearized Boltzmann equation in Eqs. (B12). For our system with the transition rate provided by Eq. (7), they are found to be
\[
\frac{\beta}{z \tau_\eta} = \frac{\pi}{(2\sqrt{2}\pi)^d (d/2) \Gamma(d/2 + 2)} \int_0^\infty d\varepsilon \varepsilon^d e^{-\varepsilon} \times \frac{(d - 2)\Omega_{d-1}}{\left(\sqrt{2}\pi a/\lambda T\right)^{2-d} - (\varepsilon - i0^+)^{d/2-1}} \]  \hspace{1cm} \text{(B21)}
and \( \tau_\kappa = [d/(d - 1)] \tau_\eta \).

\[6\] This is the approximation identifying the collision term with \( (\partial f_p / \partial \varepsilon)_{\text{coll}} = -\delta f_p / \tau_{\eta, \kappa} \) for each transport coefficient.
Then, the substitution of Eqs. (B20) into Eqs. (B19) relates the shear viscosity and the thermal conductivity to their relaxation times as

\[ \eta = \frac{2\pi \tau_\eta}{\beta \lambda T}, \quad \kappa = \frac{(d+2)\pi \tau_\kappa}{m\beta \lambda T^2}. \]  

(B22)

Because the former with Eq. (B21) agrees with the shear viscosity obtained in Refs. [24][27], the approximate resummation scheme adopted therein assuming a simple geometric series based on the lowest two terms in fugacity turns out to correspond to the relaxation-time approximation. We also confirm that the Prandtl number defined in Eq. (41) reads

\[ \Pr = \frac{d-1}{d}, \]  

(B23)

taking the constant value independent of the scattering length \([20][29]\), which is however true only in the relaxation-time approximation.
