Patient's primary tumor-derived tumor cell lines likely represent ideal tools for human tumor biology in vitro and in vivo. Here, we describe eight human gastric carcinoma cell lines derived from established tumors in vivo upon subcutaneous transplantation of primary gastric carcinoma specimens in BALB/c nude mice. These xenografted gastric tumor cell lines (GTX) displayed close similarity with primary gastric tumor tissues in their in vivo growth pattern and genomic alterations. GTX-085 cells were resistant to cisplatin, while GTX-087 was the most sensitive cell line. GTX-085 was the only cell line showing a metastatic potential. Epithelial cell adhesion molecule (EPCAM) expression was especially strong in all tissue samples, as well as in cell cultures. GTX-139, the largest tumor graft obtained after injection, displayed distinct expression of CD44v6, fibroblast growth factor receptor 2 (FGFR2), and prominin 1 (PROM1, also known as CD133). In summary, we established eight xenograft gastric cancer cell lines from gastric cancer patient tissues, with their histological and molecular features consistent with those of the primary tumors. The established GTX cell lines will enable future studies of their responses to various treatments for gastric cancer.

Key Words: Gastric cancer, Xenograft, Cell line, FGFR2 amplification, Targeted therapy

INTRODUCTION

Although the gastric carcinoma (GC) mortality rate has decreased worldwide, it is still high in Korea (43/100,000), especially among men (Shin et al., 2004; Ushijima and Sasako, 2004). Metastasis is the major cause of gastric cancer death (Shridhar et al., 2013). Therefore, thorough understanding of the biological nature of gastric cancer is vital to develop proper therapeutic methods and to improve the current prognosis of the disease. To achieve these goals, permanently growing cell lines derived from cancer patients may play an invaluable role in research studies.

Cancer cell lines are established from pathologically proven gastric tumors, either directly or after xenotransplantation to athymic nude mice (Park et al., 1990). Although GC has
been considered to be very difficult to culture (Park et al., 1990), more than 36 gastric cancer cell lines have been established to date, mostly from Japan and Korea, where gastric cancer mortality rates are still very high (Ushijima and Sasako, 2004; Ku et al., 2012). Established cell lines were derived either from ascites of patients with signet-ring cell GC (Yanagihara et al., 1991) or from human primary and metastatic GCs (Park et al., 1990; Park et al., 1997), and there have been few reports of spontaneous metastasis from human gastric tumor xenografts in nude mice (Yanagihara et al., 2004). Thus, it has been reported that two human signet-ring cell GC cell lines exhibited the ability to spontaneously metastasize to lymph nodes and lungs in nude mice (Yanagihara et al., 2004) and three gastric cancer cell lines derived from the liver showed a metastatic potential for the liver, lung, lymph nodes, and peritoneum (Nakanishi et al., 2005). However, the availability of cell lines to investigate the heterogeneity of GCs is still limited.

In 2007, advantages of the establishment of a cancer cell line from a tumor fragment through a xenograft stage, rather than directly from a primary tumor, were first demonstrated for colon carcinoma (Dangles-Marie et al., 2007). The authors claimed that it was technically difficult to obtain representative human colon cancer cell lines from fresh tumors. In particular, it was shown that a prior xenograft increased the efficiency of the cell line establishment compared with that of the direct establishment from fresh tumors (Dangles-Marie et al., 2007). Moreover, human colon cancer cell lines derived from the same tumor fragment using the two protocols displayed similarity in major phenotypic and genotypic characteristics such as the ability to form compact spheroids, karyotype alterations, and distinctive additional chromosomal aberrations, as well as in the expression levels of genes selected for their role in oncogenesis (Dangles-Marie et al., 2007). Although Daniel and coauthors (Daniel et al., 2009) argued that a number of tumor-specific genes expressed in primary small-cell lung cancer and xenografts were lost during the transition to tissue culture and not regained when the tumors were reestablished as secondary xenografts, such changes in gene expression may be a common feature of many cancer cell culture systems. Therefore, xenotransplantation of tumor fragments in mice before the establishment of cell lines can be considered a practical method enabling the generation of novel human cancer cell lines for the investigation of cancer cell biology and providing the opportunity to reproduce the diversity of the diseases.

Epstein-Barr virus (EBV) has a pathogenic role in several lymphomas and solid cancers and is considered to cause GC (Yoo et al., 2015). EBV-associated GC comprises nearly 10% of all GC cases worldwide (Fukayama, 2010). EBV-positive gastric cancers have been demonstrated to be more prevalent in males than in females and less likely to be found in the gastric antrum than in the cardia or body of the stomach (Young and Murray, 2003). Despite extensive studies, the mechanism underlying the gastric carcinogenesis caused by EBV remains unknown, which might be due to the lack of naturally infected EBV-positive cell lines available for studies. So far, only a few EBV-positive gastric cancer cell lines such as SNU-719, NCC-24, and YCCE1 have been established and characterized (Oh et al., 2007; Ku et al., 2012).

In the present study, we report the establishment and tumorigenic characterization of eight human GC cell lines (GTX-006, GTX-007, GTX-085, GTX-086, GTX-087, GTX-103, GTX-116, and GTX-139), established from seven Korean male and one female gastric cancer patients whose ages ranged from 59 to 76 years old. All of these eight cell lines were indirectly established from xenografts after serial heterotransplantation of gastric tumors in nude mice. Seven cell lines (GTX-006, GTX-007, GTX-085, GTX-086, GTX-087, GTX-116, and GTX-139) showed high in vivo tumorigenicity when injected subcutaneously, and five of them (GTX-006, GTX-007, GTX-085, GTX-086, GTX-116, GTX-139) also formed tumors upon injection in an orthotopic site (gastric wall) in nude mice. Interestingly, the GTX-085 cell line showed a metastatic ability to the ovary, which is rarely observed in the case of gastric cancer cell lines.

**MATERIALS AND METHODS**

**Primary tissue xenograft screening**

Twenty-two surgical specimens of primary GC were used for a xenograft model test. All patients provided written informed consent, and the collection and use of materials
for research purposes were approved by the Institutional Review Board of the Samsung Medical Center. The tissues (0.2 cm³) were subcutaneously implanted into three BALB/c nude mice (Orient Bio, Inc., Gyeonggi, Korea). Xenograft tumors were established for 12–16 weeks, and their sizes were monitored. The 22 primary tissues showed tumorigenicity 3 weeks after the mouse subcutaneous implantation. A serial passage was performed in vivo as described above, using a tumor fragment when the xenograft tumor size reached 1,000 mm³. A clinicopathological summary of the 22 tumors used for xenografts is described in Supplementary Table 1.

**Xenograft cell line establishment and culture**

The xenograft tumor tissues derived from primary tissues subcutaneously implanted into the mice were mechanically and enzymatically dissociated. After washing with phosphate-buffered saline (PBS), minced tissue was mixed with an enzyme cocktail containing 0.4 mg/mL collagenase (Gibco, Waltham, MA, USA), 0.5 mg/mL DNase I (Roche, Basel, Switzerland), and 0.2 mg/mL dispase (Gibco, Waltham, MA, USA) in RPMI 1640 medium (Gibco, Waltham, MA, USA) and incubated at 37°C for 2 h with shaking. Dissociated tissue was filtered through a 40-μm cell strainer (BD Biosciences, San Jose, CA, USA) and washed with PBS. Isolated cells were cultured in RPMI 1640 medium containing 10% fetal bovine serum (FBS) and 1% penicillin/streptomycin (Gibco, Waltham, MA, USA). Mycoplasma contamination was examined using a MycoAlert kit (Lonza, Basel, Switzerland).

**Array comparative genomic hybridization analysis**

Genomic DNA (gDNA) was extracted from tissue for pathology quality control using a QIAGen DNA mini kit (Cat. No. 51306, Qiagen, Hilden, Germany). The amount and quality of extracted gDNA were assessed using a Nanodrop spectrophotometer (ND-1000). Array comparative genomic hybridization (aCGH) analysis was performed using a SurePrint G3 human CGH microarray kit 8×60K (Agilent, G4450A) following the manufacturer’s instructions. Briefly, gDNA (500 ng) was digested with the restriction endonucleases AluI and Rsal at 37°C for 20 min. Then, random primers were added to the sample, and it was incubated for fluorescent labeling at 95°C for 3 min and on ice for 5 min. Experimental gDNA and reference gDNA were incubated with labeling master mixtures containing cyanine 3-dUTP and cyanine 5-dUTP at 37°C for 2 h and at 65°C for 10 min, respectively (Agilent genomic DNA enzymatic labeling kit, p/n 5190-0449). After the incubation, samples were cleaned using an Amicon Ultra-0.5 Ultracel-30 membrane, 30 kDa (Millipore, Billerica, MA, USA).

**DNA fingerprinting**

gDNA from each cell line was amplified using an AmpFiSTR identifier polymerase chain reaction (PCR) amplification kit (Applied Biosystems, Foster City, CA, USA). A single PCR amplified 15 tetranucleotide repeat loci (D8S1179, D21S11, D7S820, CSF1PO, D3S1358, THO1, D13S317, D16S539, D2S1338, D19S433, vWA, TPOX, D18S51, D5S818, and FGA) and the amelogenin sex determination marker at loci containing highly polymorphic microsatellite markers. Amplified products were analyzed using the GeneMapper 4.0 software (Applied Biosystems, Foster City, CA, USA).

**Cell viability assay with antitumor drugs**

5-Fluorouracil (5-FU) was obtained from Choongwae Pharma Corp. (Gyeonggi, Korea), and cisplatin was obtained from Dong-A Pharmaceutical (Seoul, Korea). Cell viability was evaluated using a CellTiter-Glo luminescent cell viability assay (Promega, Madison, WI, USA) per manufacturer's instructions. Briefly, 5,000 cells were treated with five different concentrations of 5-FU (0.9375 to 240 μg/mL) and cisplatin (0.5 to 8 μg/mL) in a 96-well plate for 72 h. Cell growth inhibition was detected as a luminescent signal of survived cells, and the concentration required to inhibit cell growth by 50% (IC50) was determined. Each experiment was conducted three times.

**Cell line xenograft assay**

Gastric tumor xenograft (GTX) cell lines were resuspended in a 1:1 mixture of Hank’s balanced salt solution (HBSS; Gibco, Waltham, MA, USA) and Matrigel (BD Biosciences, San Jose, CA, USA) to give a final volume of 100
μL. Cells (1~2.5 × 10^6) were injected subcutaneously to 7-week-old female BALB/c nude mice (for EBV-negative cell lines) or NSG mice (for EBV-positive cell lines). Tumors were measured with calipers every 2 days (the largest length and width), and the mice were weighed. The mice were housed in filter-top cages containing a maximum of five mice per cage at a 12-h light/dark cycle and were provided free access to food and water. Tumor volumes (mm³) were calculated using the following formula: width² (mm²) × length (mm) × 0.5. For orthotropic injection, 1~2.5 × 10^6 cells resuspended in 100 μL of HBSS were injected into the middle wall of the greater curvature of an anesthetized mouse. Magnetic resonance imaging was performed every week to detect tumor growth. At 6~12 weeks after the injection, the grafts were dissected and processed for further studies.

**Immunocytochemistry**

To determine whether novel established cell lines were of epithelial origin, we measured expression of cytokeratin by immunofluorescence. Cells were grown in RPMI 1640 medium on cover slips placed in 6-well plates. The cells were then fixed with 4% paraformaldehyde, permeabilized with 0.25% Triton X-100, and incubated with 5% (w/v) bovine serum albumin in PBS for 30 min at room temperature. The cells were immunostained using a fluorescein isothiocyanate (FITC)-conjugated anti-cytokeratin antibody (Miltenyi Biotech, Inc., Auburn, CA, USA) to visualize their immunoreactivity. The stained cells were mounted with the Prolong gold antifade reagent containing 4',6-diamidino-2-phenylindole (Invitrogen, Carlsbad, CA, USA) and examined using a spectral confocal system (LSM 710, Zeiss, Oberkochen, Germany).

**Hematoxylin and eosin staining and immunohistochemistry**

A tumor mass was fixed in 4% formalin for 24~48 h, embedded in paraffin, and sectioned at 4 μm. Tissues on slides were stained with hematoxylin and eosin (H&E) for 30 s, respectively. Serial sectioned tissue slides were deparaffinized in xylene, rehydrated in 70, 80, 90, 95, and 100% alcohol for 5 min, and washed with distilled water. The hydrated slides were treated with an antigen retrieval solution (Dako REAL™ target retrieval solution, 10×, pH 6.0) for 40 min in a water bath at 98°C and then blocked in a Dako REAL™ peroxidase blocking solution (0.3% H₂O₂ in methanol). Sections were incubated with primary antibodies for 1 h at room temperature. After washing with PBS-Tween 20 (0.1 M PBS, 0.5% Tween 20, pH 7.4), an EnVision™ detection system was used according to the manufacturer's instruction (Dako, Santa Clara, CA, USA). To obtain clear results, the following optimal antibodies were used: anti-CD44v6 (Abcam, 1:200), anti-CD133/1 (Miltenyi Biotech, 1:200), anti-EPCAM (Santa Cruz Biotechnology, 1:200), anti-FGFR2 (Abcam, 1:150), and anti-THY1 (Cell Signaling Technology, 1:100).

**Immunoblotting**

Total proteins were isolated using a Pro-Prep protein extraction solution (Intron Biotechnology, Gyeonggi, Korea). Then, 25~30 μg of protein was subjected to 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis and electrotransferred onto nitrocellulose membranes. The membranes were blocked with 5% nonfat dry milk in Tris-buffered saline containing 0.1% (v/v) Tween 20 and then probed overnight at 4°C with CD44v6 (1:500; R&D Systems, Minneapolis, MN, USA), FGFR2 (1:500; Abcam, Cambridge, UK), EPCAM (1:250; Santa Cruz Biotechnology, Dallas, TX, USA), THY1 (1:1,000; Cell Signaling Technology, Danvers, MA, USA), and β-actin (1:5,000; Sigma-Aldrich, St. Louis, MO, USA) antibodies. A horseradish peroxidase-conjugated anti-rabbit or anti-mouse IgG was used as a secondary antibody, and signals were detected by chemiluminescence.

**Statistical analysis**

To compare results, the Student's t-test or Mann-Whitney U-test was performed for independent variables, and the paired t-test or Wilcoxon signed-rank test was performed for related variables as appropriate, using SPSS version 15.0 (SPSS, Inc., Chicago, IL, USA).
RESULTS

Establishment of novel gastric tumor xenograft cell lines and culture

Eight cell lines (GTX-006, GTX-007, GTX-085, GTX-086, GTX-087, GTX-103, GTX-116, and GTX-139) were established from 22 xenograft tissues. Cells were dissociated from xenograft tissues of primary gastric cancer tissues and successfully cultured in 10% FBS-supplemented RPMI 1640 media (Fig. 1A). Supplementary Table 1 shows a summary of clinicopathologic data. Interestingly, four cell lines (GTX-006, GTX-007, GTX-085, and GTX-139) were poorly differentiated tubular adenocarcinomas, whereas moderately differentiated tumors constituted more than 50% of the 22 xenografts of primary gastric cancer tissues. The in vivo passage numbers of the xenograft tissues used for cell culture were P2-P6 (Table 1). When analyzing their growth properties (Fig. 1A), GTX-006 and GTX-007 cells showed a round shape, and some floating cell aggregates were observed. GTX-085 cells grew as a round-cell monolayer, with most cells attached and some cells floating. GTX-086 cells formed an attached dense monolayer; and some round-shaped suspended cells were observed. GTX-087 cells were adherent and grew as round cells in aggregates. GTX-103 cells grew as a monolayer, and individual cells displayed a polygonal shape. GTX-116 and GTX-139 cells were round; most cells were attached, and some cells were floating as single cells. All results are described in Table 1.

Identification and characterization of GTX cell lines

To confirm that the xenograft tumors corresponded to the primary patient tumors, we conducted histological analysis and DNA fingerprinting. Based on the Lauren classification, the primary tumors of the GTX-006 and GTX-007 cell lines were of diffuse type, and those of the GTX-085, GTX-087, GTX-116, and GTX-139 cell lines were of intestinal type. The xenograft tissues used for cell line culture displayed similarity with the primary gastric tumor tissues as shown in Fig. 1B and 1C. Using DNA fingerprinting, we detected heterogeneity among 15 tetranucleotide repeat loci and the amelogenin sex determination marker between the primary gastric tumor tissues and xenograft tissues used for cell culture (Table 2). STR profile of xenograft tissues were concordant to those of the primary tissues. Based on the aCGH analysis, abnormal chromosome ploidy levels in the primary gastric tumor tissues corresponded to those in the xenograft tissues used for cell culture (Supplementary Fig. 1). In some cases (e.g., GTX-086 and GTX-103), the xenograft tissues showed more severe genomic abnormalities, indicating that xenograft tissues were more similar to tumor cells than to primary tissues. To examine the sensitivity of the novel cell

Table 3. Summary of in vivo tumorigenicity screening analysis of GTX cell lines

| Cell lines | Subcutaneous | Orthotopic |
|------------|--------------|------------|
|            | Number of cells injected | Tumor* | Number of cells injected | Tumor* | Metastasis |
| GTX-006    | 2.46 × 10^6  | 2/3        | 2.46 × 10^6  | 2/2     | x          |
| GTX-007    | 1.13 × 10^6  | 2/2        | 1.13 × 10^6  | 1/2     | x          |
| GTX-085    | 1.00 × 10^6  | 1/2        | 1.00 × 10^6  | 2/3     | Ovary      |
| GTX-086    | 2.00 × 10^6  | 2/2        | ND           | ND      | ND         |
| GTX-103    | 2.50 × 10^6  | 1/2        | 2.50 × 10^6  | 0/2     | x          |
| GTX-116    | 1.00 × 10^6  | 1/1        | 1.00 × 10^6  | 1/3     | x          |
| GTX-139    | 2.50 × 10^6  | 2/2        | 2.50 × 10^6  | 2/3     | x          |

*Number of mice with tumor growths / total number of mice with injection

formed on the GTX cell lines showed that cytokeratin was expressed in all the GTX cell lines (Fig. 1D).

High tumorigenicity of gastric tumor xenograft cell lines

The tumorigenicity and metastatic potential of the eight GTX cell lines in mice are summarized in Table 3. Seven cell lines, except GTX-103, showed high tumorigenicity in 4–6 weeks after subcutaneous injection to nude mice (Fig. 2A). In the case of GTX-086, which was derived from an EBV-positive gastric cancer, cells were injected to NSG mice (Fig. 2B). After cells were orthotopically injected into the stomach serosa, five cell lines (GTX-006, GTX-007, GTX-085, GTX-116, and GTX-139) formed tumor grafts (Fig. 2C). Among these, the GTX-085 line spontaneously meta-
Histological features of these xenograft tumors were similar to those of their primary tumors.

Distribution of cancer stem cell markers in GTX cell lines

Cancer stem cells (CSCs) are regarded as the driving force of tumor formation in vivo, responsible for antitumor
resistance. To identify the presence of gastric CSCs, expression of several markers was evaluated by Western blotting in seven GTX cell lines (except GTX-086) (Fig. 3A). Epithelial cell adhesion molecule (EPCAM) was expressed in all the GTX cell lines, and CD44v6 was expressed in GTX-007, GTX-85, GTX-087, GTX-116, and GTX-139. Fibroblast growth factor receptor 2 (FGFR2) was strongly expressed in GTX-087, and THY1 membrane glycoprotein was expressed in five GTX cell lines, except GTX-087 and GTX-103.

Immunohistochemistry was performed to detect the expression of CSC markers on tumor grafts obtained after subcutaneous injection of GTX cell lines to nude mice (Fig. 3B). EPCAM expression was especially strong in all samples, similar to the cell cultures, and GTX-139, the largest tumor graft formed after the injection (Fig. 2A), displayed distinct expression of CD44v6, FGFR2, and prominin 1 (PROM1, also known as CD133).

**DISCUSSION**

Most of the current research on the biology of gastric cancer is based on *in vivo* and *in vitro* experiments performed with gastric cancer cell lines. Because authentic cultured cells can be applied to many studies, when tissue specimens are not available, permanent cell lines established from human cancers have played an important role in the understanding of the biology of cancers (Ku et al., 2012). The present study describes eight gastric cancer cell lines established from xenograft tumor tissues, which originated from transplantation of primary tissue. Each cell line was shown to be unique and related to the primary tissue at the DNA level, as shown by fingerprinting analysis. None of the cell lines was contaminated by mycoplasmas or bacteria.

Animal models play a crucial role in drug development and research on cancer biology. Various animal models have been established for the investigation of carcinogenic mechanisms and prediction of targeted therapies (Richmond and Su, 2008). However, generation of animal models using primary tumor tissue is time-consuming and expensive, and thus its application is limited in the research of anticancer drug responses. The eight cell lines from our study showed high tumorigenicity in a few weeks, and their relevant tumor biology mirrored the histochemical and biochemical features of the primary gastric tumors. However, further investigation on the differences between direct culture of primary tissue and xenograft tissue culture cell lines should be performed for elucidating the efficiency of GTX cell lines.

The CD44 isoform overexpression is significantly associ-
ated with tumor progression, tumorigenicity, growth, metastasis, and prognosis of many carcinomas in humans. Binding of CD44 with its ligands may induce the production of autocrine growth factors, which play an important role in tumor growth (Kodama et al., 2017). Our data from the in vivo tumorigenesis screening of the GTX cell lines revealed that CD44v6 expression was correlated with the tumor growth rate and tumor size. Thus, GTX-006 showed a low level of expression of CD44v6 and low tumorigenicity, while GTX-116 exhibited high tumorigenicity and overexpression of CD44v6.

Metastasis of gastric cancer occurs via hematogenous and lymphogenous routes, peritoneal seeding, and direct invasion. Metastasis is a very complex process, involving multiple consecutive steps (Fidler, 2002). A mouse model of metastatic gastric cancer is an extremely valuable tool to study the metastatic process. In the present study, the mice injected orthotopically with GTX-085 developed tumor growth at the injected position and ovary metastasis. This cell line facilitated research of Krukenberg tumor, poor prognostic features associated with GC metastasis to the ovary (Lee et al., 2015; Jung et al., 2017).

Recent studies have reported an association of EBV with 6–16% of gastric cancer cases worldwide (Shibata et al., 1993; van Beek et al., 2002). EBV-positive gastric cancer cell lines such as SNU-719, NCC-24, and YCCE1 have been established and characterized (Oh et al., 2007; Ku et al., 2012). However, attempts to obtain stable EBV-positive cell lines from carcinoma tissues have been largely unsuccessful since the EBV genome tends to be lost during in vitro passages (Lin et al., 1994). Our data on the naturally EBV-infected GTX-086 line, obtained in the present study, also showed that the EBV RNA disappeared as the passage number increased (Supplementary Fig. 2).

In summary, we established eight xenograft cell lines from gastric cancer patient tissues, with their histological and molecular features consistent with those of the primary tumors. Patient-derived xenograft cell lines represent ideal tools for studying tumorigenicity of human stomach cancers in vitro and in vivo. The established GTX cell lines will enable future studies on their responses to different treatments of gastric cancer.

**ABBREVIATIONS**
- aCGH, array comparative genomic hybridization
- CSC, cancer stem cell
- EBV, Epstein-Barr virus
- EPCAM, epithelial cell adhesion molecule
- FBS, fetal bovine serum
- FGFR2, fibroblast growth factor receptor 2
- FITC, fluorescein isothiocyanate
- 5-FU, 5-fluorouracil
- GC, gastric carcinoma
- gDNA, genomic DNA
- GTX, gastric tumor xenograft
- HBSS, Hank’s balanced salt solution
- H&E, hematoxylin and eosin
- PBS, phosphate-buffered saline
- PCR, polymerase chain reaction
