Abstract

Climate change is caused by emission of greenhouse gases (GHGs) through anthropogenic activities including land-use change, deforestation, biomass burning, draining of wetlands, soil cultivation and fossil fuel combustion. Consequently, the concentration of atmospheric greenhouse gases and their radiative forcing have progressively increased with increase in human population, especially from the onset of industrial revolution around 1850. Thus, unless necessary steps are not taken to reduce CO2 emissions by increasing carbon sinks in terrestrial ecosystem alone, it is not possible to stabilize or reduce concentration of CO2 in the atmosphere.

Keywords: Greenhouse; Population growth; Carbon dioxide; Methane; Nitrous oxide

Introduction

Trends in Rise in Atmospheric Carbon Dioxide Concentration

Anthropogenic greenhouse gas emissions have increased since the pre-industrial era, driven largely by industrial and population growth, and are now higher than ever. This has led to atmospheric concentrations of carbon dioxide, methane and nitrous oxide reach unprecedented levels. Their effects, together with those of other anthropogenic drivers, have been detected throughout the climate system and are extremely likely to have been the dominant cause of the observed warming since the mid-20th century. Changes in many extreme weather and climate events have been observed since about 1950 IPCC [1]. Some of these changes have been linked to human influences, including a decrease in cold temperature extremes, an increase in warm temperature extremes, an increase in sea level and an increase in the number of heavy precipitation events in a number of regions. It has been observed that CO2 emission is on the rise and may continue to rise for many more years due to our dependence on fossil fuels IPCC [2].

Trees Alone Cannot be the Answer to Climate Change

Accumulation of CO2 in the atmosphere is a dynamic function of the balance between the amount of CO2 emitted by the world and the total amount of CO2 sequestered by the planet (through photosynthesis) during a given period of time.

\[ \text{Atmospheric CO}_2\text{concentration} = \text{CO}_2\text{Emission} - \text{CO}_2\text{Sequestration} \quad \text{Eqn. (1)} \]

From the above equation, it is evident that growing more trees can reduce atmospheric CO2 concentration. Globally, the rate of deforestation is much larger than that of reforestation. Recent studies estimated a net emission of GHGs from the Mato Grosso region of Brazilian Amazon, ranging from 2.8 to 15.9 Gt CO2-eq from 2006 to 2009 [3,4]. It was reported that between 1996 and 2005, the Brazilian Amazon rainforest was deforested by 19,500 km2 per year and converted to pastures and farmland releasing 0.7 to1.4 Gt CO2-eq yr\(^{-1}\) to the atmosphere [5]. Avoided deforestation is the best means of Afforestation, new and massive efforts at planting more trees should be a parallel strategy in order to reduce build-up of CO2 in the atmosphere. Many governments around the world, including India have taken up massive tree planting programmes with the slogan that trees are the answer to global warming.

While growing trees is a good idea and tree planting programmes should continue with greater zeal for their numerous ecosystem services, the present analyses shows that as long as the present emission trends continue, even if we manage to convert the entire land on the planet into a forest, that will not be adequate to completely offset the current rate of build-up of CO2 in the atmosphere and prevent or limit global warming. It has been reported earlier that if all countries in the world would have emitted GHGs into the atmosphere at the same rate as some developed nations did, we would need nine planets to keep the atmospheric concentration of GHGs at the present level HDR [6]. Published data on the global carbon budget shows that build-up of CO2 in the atmosphere is determined more by the amount of global CO2 emission rather than the CO2 sequestration by the planet and therefore, proactively reducing emission is more effective than
planting more trees in reducing and stabilizing the concentration of CO$_2$ in the atmosphere.

**Rate of Increase in the world CO$_2$ Emission and Atmospheric CO$_2$ Concentration between the Period 1950 and 2008:**

Long term data on CO$_2$ emission and atmospheric CO$_2$ concentration were obtained from authentic published sources (http://data.worldbank.org/indicator). Data on terrestrial and ocean CO$_2$ fluxes were taken from the fourth assessment report (AR4) of the Intergovernmental Panel on Climate Change IPCC [2]. Using these data, rate of increase in GHG emission and removal from the atmosphere and increase in the concentration of CO$_2$ in the atmosphere were calculated through regression analysis. The present rate of terrestrial and oceanic removal of CO$_2$ and the rate of build-up of CO$_2$ concentration in the atmosphere were used to estimate the area of land and ocean that is required to fully offset the rise of CO$_2$ in the atmosphere. Linear regression analysis shows that the annual rate of increase in CO$_2$ emission between 1950 and 2008 was 411.30 Mt CO$_2$ per year ($R^2 = 0.98$) and the atmospheric CO$_2$ concentration increased at the rate of 1.30 ppm per year which is equivalent to 10151.06 Mt CO$_2$ per year ($R^2 = 0.97$). Between 1950 and 2008, CO$_2$ emission (including fossil fuel combustion and land use changes) increased from 9450 Mt to 34939 Mt. During the same period, atmospheric CO$_2$ concentration increased from 311 ppm to 386 ppm (Figure 1).

From the emission and atmospheric CO$_2$ concentration data, I calculated the amount of CO$_2$ sequestered as the difference between the former two. The rate of CO2 emission (including fossil fuel combustion and land use changes) increased from 9450 Mt to 34939 Mt. During the same period, atmospheric CO$_2$ concentration increased from 311 ppm to 386 ppm (Figure 1).

![Figure 1: Rate of increase in the world CO$_2$ emission and atmospheric CO$_2$ concentration between the period 1950 and 2008 (Calculated based on the data from Carbon dioxide information analysis center (CDIAC).)](image1)

The increase in CO$_2$ emission was 270% while atmospheric CO$_2$ concentration increased only to the tune of 24%. Despite the huge increase in CO$_2$ emission, the atmospheric CO$_2$ did not increase to the same extent and this indicates that the amount of CO$_2$ sequestered by the planet must have increased at a rate greater than the rate at which CO$_2$ increased in the atmosphere between 1950 and 2008. Terrestrial removal of CO$_2$ during 2000-2005 was 0.9 Gt C yr$^{-1}$ IPCC [2] and this is equal to 3303.0 Mt CO$_2$ per year. Total vegetation area on earth surface is about 15000 M ha [7]. From this it is calculated that the terrestrial carbon fixation rate comes to 220 Kg CO$_2$ per hectare per year. At this rate, we need an additional land area of around 46141.0 M ha for planting trees so as to fully offset the current rate of increase in atmospheric CO$_2$ concentration (which is roughly 1.30 ppm yr$^{-1}$, averaged for the period 1950-2008, Figure 2). This is equal to the terrestrial vegetation area of three planets.

From the emission and atmospheric CO$_2$ concentration data, I calculated the amount of CO$_2$ sequestered as the difference between the former two. The rate of CO2 emission (including fossil fuel combustion and land use changes) increased from 9450 Mt to 34939 Mt. During the same period, atmospheric CO$_2$ concentration increased from 311 ppm to 386 ppm (Figure 1).

The increase in CO$_2$ emission was 270% while atmospheric CO$_2$ concentration increased only to the tune of 24%. Despite the huge increase in CO$_2$ emission, the atmospheric CO$_2$ did not increase to the same extent and this indicates that the amount of CO$_2$ sequestered by the planet must have increased at a rate greater than the rate at which CO$_2$ increased in the atmosphere between 1950 and 2008. Terrestrial removal of CO$_2$ during 2000-2005 was 0.9 Gt C yr$^{-1}$ IPCC [2] and this is equal to 3303.0 Mt CO$_2$ per year. Total vegetation area on earth surface is about 15000 M ha [7]. From this it is calculated that the terrestrial carbon fixation rate comes to 220 Kg CO$_2$ per hectare per year. At this rate, we need an additional land area of around 46141.0 M ha for planting trees so as to fully offset the current rate of increase in atmospheric CO$_2$ concentration (which is roughly 1.30 ppm yr$^{-1}$, averaged for the period 1950-2008, Figure 2). This is equal to the terrestrial vegetation area of three planets.
Mahatma Gandhi reflected on how many planets might be needed to sequester the total emission if India were to follow Britain’s pattern of industrialization. Carbon capture and storage (CCS) [9], which amounts to physically trapping CO$_2$ at its source and storing it in large underground geological formations is perhaps the only way we can continue to emit CO$_2$ at the present levels and yet stabilize its atmospheric concentration at some specified level, but this technology is yet to be fully harnessed. While planting trees is not only option for mitigation of climate change but reducing or even stabilizing the concentration of CO$_2$ in the atmosphere at the present level cannot be achieved, unless there are deliberate efforts in reducing the amount of anthropogenic CO$_2$ emission into the atmosphere IPCC [2].

Conclusion

It is clearly shown that the world is emitting much more CO$_2$ than it can sequester and hence, in equilibrium is on the rise. The result is that CO$_2$ concentration in the atmosphere is increasing at an alarming rate. Planting trees is not only the option to bring this equilibrium back, unless there are deliberate efforts in reducing the amount of anthropogenic CO$_2$ emission into the atmosphere. Emissions and land use changes) from 1950-2008 was $0.12$ Gt C yr$^{-1}$. The rate of removal of CO$_2$ from the atmosphere (including land and ocean sinks of CO$_2$) and the rate of addition of CO$_2$ to the atmosphere were identical ($0.06$ Gt C yr$^{-1}$) (Figure 1). The rate of emission was much greater than the rate of removal and the difference was $0.06$ Gt C yr$^{-1}$. This indicates that even if we take the sequestration capacity of the land and ocean together, we will still require one more additional planet to remove the current rate of CO$_2$ emission to maintain equilibrium between the present emission and removal and thus keep the atmospheric CO$_2$ concentration stabilized at the present level.
