Splitting theorems for Finsler manifolds of nonnegative Ricci curvature

Shin-ichi Ohta*

October 16, 2018

Abstract

We investigate the structure of a Finsler manifold of nonnegative weighted Ricci curvature including a straight line, and extend the classical Cheeger-Gromoll-Lichnerowicz splitting theorem. Such a space admits a diffeomorphic, measure-preserving splitting in general. As for a special class of Berwald spaces, we can perform the isometric splitting in the sense that there is a one-parameter family of isometries generated from the gradient vector field of the Busemann function. A Betti number estimate is also given for Berwald spaces.

1 Introduction

The Ricci curvature is one of the most important quantities in geometry and analysis on Riemannian manifolds. The Ricci curvature (or tensor) plays prominent roles in various ways, from the classical comparison theorems due to Rauch and Bishop to Hamilton and Perelman’s celebrated theory of the Ricci flow. Recently, it turned out that the Ricci curvature is quite useful also in the study of Finsler manifolds. A Finsler manifold is a manifold endowed with a (Minkowski) norm on each tangent space. Inspired by the theory of weighted Riemannian manifolds, the weighted Ricci curvature \( \text{Ric}_N \) was introduced in \([\text{Oh3}]\) for a Finsler manifold \((M, F)\) equipped with an arbitrary measure \(m\) on \(M\), where \(N \in [\dim M, \infty] \) is a parameter (see Definition 2.4). Bounding \( \text{Ric}_N \) from below by \( K \in \mathbb{R} \) (i.e., \( \text{Ric}_N(v) \geq K F(v)^2 \)) is equivalent to Lott, Sturm and Villani’s curvature-dimension condition \( \text{CD}(K, N) \) \([\text{Oh3}]\). This equivalence has many applications via the general theory of the curvature-dimension condition, such as the Bishop-Gromov volume comparison and the Lichnerowicz inequality on the spectral gap (see \([\text{Oh3}]\)). Furthermore, the Laplacian comparison theorem for a natural nonlinear Laplacian \([\text{OS1}]\) as well as the Bochner-Weitzenböck formula \([\text{OS3}]\) hold.

The aim of this article is to generalize another fundamental theorem in comparison geometry involving the Ricci curvature, Cheeger and Gromoll’s splitting theorem \([\text{CG1}]\), that asserts that a Riemannian manifold \((M, g)\) of nonnegative Ricci curvature including

*Department of Mathematics, Kyoto University, Kyoto 606-8502, Japan (sohta@math.kyoto-u.ac.jp); Supported in part by the Grant-in-Aid for Young Scientists (B) 23740048.
a straight line admits an isometric splitting $M = M' \times \mathbb{R}$. This splitting theorem was extended to weighted Riemannian manifolds by Lichnerowicz and others ([Li], [FLZ], [WW]), and to (weighted) Alexandrov spaces by introducing appropriate notions of the lower Ricci curvature bound ([KS], [ZZ]).

In the Finsler case, as normed spaces (equipped with the Lebesgue measure) have the nonnegative Ricci curvature, the isometric splitting can not be expected. Nevertheless, our first main result (Corollary 4.4) asserts that a diffeomorphic and measure-preserving splitting holds for general Finsler manifolds. The proof is essentially parallel to the Riemannian case, thanks to the Laplacian comparison theorem in [OS1]. One can describe the splitting in more details for Berwald spaces. Roughly speaking, a Berwald space is a Finsler manifold modeled by a single normed space (see Proposition 2.11). For example, Riemannian manifolds, normed spaces, and their products are Berwald spaces. In the Berwald case, we can also split the metric in the sense that there exists an $l$-parameter family of isometries $\varphi_p : M \rightarrow M$, $p \in \mathbb{R}^l$, such that $\bigcup_{p \in \mathbb{R}^l} \varphi_p(M) = M$, where the $(\dim M - l)$-dimensional submanifold $\overline{M} \subset M$ is characterized by the property that any Busemann function is constant on $\overline{M}$ (see Theorem 5.4 for the precise statement). A Betti number estimate along the lines of [CG1], [CG2] is also given in the Berwald case (Theorem 5.6).

The study of Finsler manifolds has an extra importance from the view of the curvature-dimension condition. As we mentioned above, Finsler manifolds give a nice class of model spaces satisfying the curvature-dimension condition. One can use this class as a test to see what properties of Riemannian manifolds of Ricci curvature bounded below can be or can not be expected to hold for general metric measure spaces satisfying the curvature-dimension condition (in other words, to see whether such a property depends only on the ‘Ricci curvature bound’, or it also requires that the space is ‘Riemannian’). For instance, the contraction property of the heat flow with respect to the $L^2$-Wasserstein distance fails on (non-Riemannian) Finsler manifolds ([OS2]). Recently, the contraction property was shown in [AGS] for metric measure spaces by assuming $\text{CD}(K, \infty)$ and the linearity of the heat flow (the linearity means that the space is ‘Riemannian’ in a sense). The Bochner-Weitzenböck formula also holds in such a case (see also [GKO]), whereas it is unclear how to remove the linearity.

The article is organized as follows. We review necessary notions in geometry and analysis on Finsler manifolds in Section 2. Section 3 is devoted to the study of Busemann functions. We show splitting theorems in Sections 4, 5 in the general and Berwald cases, respectively.

## 2 Geometry and analysis on Finsler manifolds

We review the basics of Finsler geometry (we refer to [BCS] and [Sh1] for further reading), and introduce the weighted Ricci curvature and the nonlinear Laplacian studied in [Oh3] and [OS1] (see also [GS]). Throughout the article, let $M$ be a connected, $n$-dimensional $C^\infty$-manifold without boundary such that $n \geq 2$. We fix an arbitrary positive $C^\infty$-measure $m$ on $M$ as our base measure.
2.1 Finsler manifolds

Given a local coordinate \((x^i)_{i=1}^n\) on an open set \(\Omega \subset M\), we will always use the coordinate \((x^i, v^j)_{i,j=1}^n\) of \(T\Omega\) such that

\[
v = \sum_{j=1}^n v^j \frac{\partial}{\partial x^j} \bigg|_x \in T_x M \quad \text{for } x \in \Omega.\]

**Definition 2.1 (Finsler structures)** A nonnegative function \(F : TM \rightarrow [0, \infty)\) is called a \(C^\infty\)-Finsler structure of \(M\) if the following three conditions hold.

1. **(Regularity)** \(F\) is \(C^\infty\) on \(TM \setminus 0\), where 0 stands for the zero section.
2. **(Positive 1-homogeneity)** It holds \(F(cv) = cF(v)\) for all \(v \in TM\) and \(c > 0\).
3. **(Strong convexity)** The \(n \times n\) matrix \((g_{ij}(v))_{i,j=1}^n := \left(\frac{1}{2} \frac{\partial^2 (F^2(v))}{\partial v_i \partial v_j} \right)_{i,j=1}^n\) is positive-definite for all \(v \in TM \setminus 0\).

We call such a pair \((M, F)\) a \(C^\infty\)-Finsler manifold.

That is to say, \(F|_{T_x M}\) is a smooth Minkowski norm for every \(x \in M\), and \(F\) varies smoothly also in the horizontal direction. We will denote the unit tangent sphere bundle by \(UM := TM \cap F^{-1}(1)\). For \(x, y \in M\), we define the distance from \(x\) to \(y\) in a natural way by

\[
d(x, y) := \inf_{\eta} \int_0^1 F(\dot{\eta}(t)) \, dt,
\]

where the infimum is taken over all \(C^1\)-curves \(\eta : [0, 1] \rightarrow M\) such that \(\eta(0) = x\) and \(\eta(1) = y\). We remark that our distance can be nonsymmetric (namely \(d(y, x) \neq d(x, y)\)) since \(F\) is only positively homogeneous. A \(C^\infty\)-curve \(\eta\) on \(M\) is called a geodesic if it is locally minimizing and has a constant speed (i.e., \(F(\dot{\eta})\) is constant). See (2.7) below for the precise geodesic equation. Given \(v \in T_x M\), if there is a geodesic \(\eta : [0, 1] \rightarrow M\) with \(\dot{\eta}(0) = v\), then we define the exponential map by \(\exp_x(v) := \eta(1)\). We say that \((M, F)\) is forward complete if the exponential map is defined on whole \(TM\). Then by the Hopf-Rinow theorem any pair of points is connected by a minimal geodesic (cf. [BCS, Theorem 6.6.1]).

For each \(v \in T_x M \setminus 0\), the positive-definite matrix \((g_{ij}(v))_{i,j=1}^n\) in (2.1) induces the Riemannian structure \(g_v\) of \(T_x M\) as

\[
g_v \left( \sum_{i=1}^n a_i \frac{\partial}{\partial x^i} \bigg|_x, \sum_{j=1}^n b_j \frac{\partial}{\partial x^j} \bigg|_x \right) := \sum_{i,j=1}^n a_i b_j g_{ij}(v). \tag{2.2}
\]

This inner product is regarded as the best Riemannian approximation of \(F|_{T_x M}\) in the direction \(v\), and plays a vital role in the Riemannian geometric approach to Finsler geometry. A geometric way of introducing \(g_v\) is that the unit sphere of \(g_v\) is tangent to that of \(F|_{T_x M}\) at \(v/F(v)\) up to the second order. In particular, we have \(g_v(v, v) = F(v)^2\).

For later convenience, we recall a useful fact on homogeneous functions.
Theorem 2.2 (cf. [BCS, Theorem 1.2.1]) Suppose that a differentiable function $H : \mathbb{R}^n \setminus \{0\} \rightarrow \mathbb{R}$ satisfies $H(cv) = c^r H(v)$ for some $r \in \mathbb{R}$ and all $c > 0$ and $v \in \mathbb{R}^n \setminus \{0\}$ (that is, $H$ is positively $r$-homogeneous). Then we have

$$
\sum_{i=1}^{n} \frac{\partial H}{\partial v^i}(v)v^i = rH(v) \quad \text{for all } v \in \mathbb{R}^n \setminus \{0\}.
$$

The Cartan tensor

$$
A_{ijk}(v) := \frac{F(v)}{2} \frac{\partial g_{ij}}{\partial v^k}(v) \quad \text{for } v \in TM \setminus 0
$$

is a quantity appearing only in the Finsler context. Indeed, $A_{ijk}$ vanishes everywhere on $TM \setminus 0$ if and only if $F$ comes from a Riemannian metric. As $g_{ij}$ is positively 0-homogeneous on each $T_x M \setminus 0$, Theorem 2.2 yields

$$
\sum_{i=1}^{n} A_{ijk}(v)v^i = \sum_{j=1}^{n} A_{ijk}(v)v^j = \sum_{k=1}^{n} A_{ijk}(v)v^k = 0 \quad (2.3)
$$

for all $v \in TM \setminus 0$ and $i, j, k = 1, 2, \ldots, n$. Define the formal Christoffel symbol

$$
\gamma^i_{jk}(v) := \frac{1}{2} \sum_{l=1}^{n} g^{il}(v) \left\{ \frac{\partial g_{lj}}{\partial x^k}(v) + \frac{\partial g_{lk}}{\partial x^j}(v) - \frac{\partial g_{jk}}{\partial x^l}(v) \right\} \quad \text{for } v \in TM \setminus 0,
$$

where $(g^{ij}(v))$ stands for the inverse matrix of $(g_{ij}(v))$. We also introduce the geodesic spray coefficient and the nonlinear connection

$$
G^i(v) := \sum_{j,k=1}^{n} \gamma^j_{ik}(v)v^jv^k, \quad N^i_j(v) := \frac{1}{2} \frac{\partial G^i}{\partial v^j}(v) \quad \text{for } v \in TM \setminus 0,
$$

and $G^i(0) = N^i_j(0) := 0$ by convention. Note that $G^i$ is positively 2-homogeneous, so that Theorem 2.2 implies $\sum_{j=1}^{n} N^i_j(v)v^j = G^i(v)$. Following another representation of $N^i_j$ (with the help of Theorem 2.2) will be used:

$$
N^i_j(v) = \sum_{k=1}^{n} \gamma^i_{jk}(v)v^k - \frac{1}{F(v)} \sum_{k,l,m=1}^{n} A^i_{jk}(v)\gamma^k_{lm}(v)v^l v^m, \quad (2.4)
$$

where $A^i_{jk} := \sum_{l=1}^{n} g^{il}A_{ijk}$.

By using $N^i_j$, the coefficients of the Chern connection are given by

$$
\Gamma^i_{jk} := \gamma^i_{jk} - \sum_{l,m=1}^{n} \frac{g^{i l}}{F} (A_{jlm}N^m_k + A_{km}N^m_j - A_{jkm}N^m_l) \quad \text{on } TM \setminus 0. \quad (2.5)
$$

That is, the corresponding covariant derivative of a vector field $X = \sum_{i=1}^{n} X^i(\partial/\partial x^i)$ by $v \in T_x M$ with reference vector $w \in T_x M \setminus 0$ is defined as

$$
D^w_v X(x) := \sum_{i,j=1}^{n} \left\{ v^j \frac{\partial X^i}{\partial x^j}(x) + \sum_{k=1}^{n} \Gamma^i_{jk}(w)v^jX^k(x) \right\} \frac{\partial}{\partial x^i} \bigg|_x \in T_x M. \quad (2.6)
$$
Then the geodesic equation is written as, with the help of (2.3),
\[ D^2_t \eta(t) = \sum_{i=1}^{n} \left\{ i^i(t) + G^i(\eta(t)) \right\} \frac{\partial}{\partial x^i} \eta(t) = 0. \] (2.7)

The following fact will be used in Section 5, we give a proof for completeness.

Lemma 2.3 If all integral curves of a non-vanishing \( C^\infty \)-vector field \( V \) are geodesic, then we have
\[ D^V_W W = D^{g_V} W, \quad D^W_V V = D^{g_V} W \]
for any differentiable vector field \( W \), where \( D^{g_V} \) stands for the covariant derivative with respect to the Riemannian structure \( g_V \) given as (2.2).

Proof. To see the claim, it suffices to compare \[ \sum_{j,k=1}^{n} \Gamma_{jk}^i(V) W^j V^k. \]
On the one hand, we observe from (2.5) and (2.3) that
\[ \sum_{j,k=1}^{n} \Gamma_{jk}^i(V) W^j V^k = \sum_{j=1}^{n} \left\{ \sum_{k=1}^{n} \gamma_{jk}^i(V) V^k - \sum_{l,m=1}^{n} \frac{g^l(V)}{F(V)} A_{jlm}(V) G^m(V) \right\} W^j. \]
On the other hand, since
\[ \frac{\partial [g_{jl}(V)]}{\partial x^k} = \partial g_{jl}(V) + \sum_{m=1}^{n} \frac{2}{F(V)} A_{jlm}(V) \frac{\partial V^m}{\partial x^k}, \]
the corresponding quantity for \( g_V \) is
\[ \sum_{j,k=1}^{n} \left\{ \gamma_{jk}^i(V) + \sum_{l,m=1}^{n} \frac{g^l(V)}{F(V)} A_{jlm}(V) \frac{\partial V^m}{\partial x^k} \right\} W^j V^k. \]
Then the geodesic equation
\[ \sum_{k=1}^{n} \frac{\partial V^m}{\partial x^k} V^k + G^m(V) = 0 \]
shows that they coincide. \( \square \)

2.2 Weighted Ricci curvature

The Ricci curvature (as the trace of the flag curvature) for a Finsler manifold is defined by using the Chern connection. Instead of giving the precise definition in coordinates, we explain an elegant interpretation due to Shen ([Sh1, §6.2], [Sh2, Lemma 2.4]).

Given a unit vector \( v \in U_x M \), we extend it to a \( C^\infty \)-vector field \( V \) on a neighborhood of \( x \) in such a way that every integral curve of \( V \) is geodesic, and consider the Riemannian structure \( g_V \) induced from (2.2). Then the flag curvature \( K(v, w) \) for \( w \in T_x M \) linearly independent with \( v \) coincides with the sectional curvature of the plane spanned by \( v \) and \( w \) with respect to \( g_V \) (in particular, it is independent of the choice of \( V \)). Similarly, the
Remark 2.6

and has many analytic and geometric applications (see [Oh3]). The result on (weighted) Riemannian manifolds (due to [vRS], [St1], [St2], [St3], [LV1], [LV2]), for example, \( v \in K \) of [72x-158] that, for each \( F \) of \( n \)-words, \( \text{Ric}(v) \) depends only on \( v \) and extend it to a \( V \) of \( C \) and extend it to a

Definition 2.7 (Reverse Finsler structure) Define the reverse Finsler structure \( \hat{F} \) of \( F \) by \( \hat{F}(v) = F(-v) \). We will put arrows \( \leftarrow \) on those quantities associated with \( \hat{F} \), for example, \( \hat{d}(x, y) = d(y, x) \), \( \hat{\nabla} u = -\nabla(-u) \) and \( \hat{\text{Ric}}_N(v) = \text{Ric}_N(-v) \).
Note that Ric_N ≥ K is equivalent to \( \overline{\text{Ric}}_N(v) \geq K\overline{F}(v)^2 \), so that the Ricci curvature bound is equivalent between \( F \) and \( \overline{F} \). We say that \((M, F)\) is \emph{backward complete} if \((M, \overline{F})\) is forward complete. The forward and backward completenesses are not mutually equivalent in general.

### 2.3 Nonlinear Laplacian

Let us denote by \( \mathcal{L}^* : T^*M \to TM \) the \emph{Legendre transform} associated with \( F \) and its dual norm \( F^* \) on \( T^*M \). Precisely, \( \mathcal{L}^* \) is sending \( \alpha \in T_x^*M \) to the unique element \( v \in T_xM \) such that \( \alpha(v) = F^*(\alpha)^2 \) and \( F(v) = F^*(\alpha) \). Note that \( \mathcal{L}^*|_{T_x^*M} \) becomes a linear operator only when \( F|_{T_xM} \) is an inner product. For a differentiable function \( u : M \to \mathbb{R} \), the \emph{gradient vector} of \( u \) at \( x \) is defined as the Legendre transform of the derivative, \( \nabla u(x) := \mathcal{L}^*(Du(x)) \in T_xM \). For a differentiable vector field \( V \) on \( M \) and \( x \in M \) such that \( V(x) \neq 0 \), we define \( \nabla V(x) \in T_x^*M \otimes T_xM \) by using the covariant derivative (2.6) as

\[
\nabla V(v) := D^V_v v \in T_xM \quad \text{for } v \in T_xM.
\]

We also set \( \nabla^2 u(x) := \nabla(\nabla u)(x) \) for a twice differentiable function \( u : M \to \mathbb{R} \) and \( x \in M \) such that \( Du(x) \neq 0 \).

Define the \emph{divergence} of a differentiable vector field \( V = \sum_{i=1}^n V^i(\partial/\partial x^i) \) on \( M \) with respect to the base measure \( m \) by

\[
\text{div}_m V := \sum_{i=1}^n \left( \frac{\partial V^i}{\partial x^i} + V^i \frac{\partial \Phi}{\partial x^i} \right),
\]

where we decomposed \( m \) in coordinates as \( dm = e^\Phi dx^1 dx^2 \cdots dx^n \). The divergence can be rewritten (and extended to weakly differentiable vector fields) in the weak form as

\[
\int_M \phi \text{div}_m V \, dm = -\int_M D\phi(V) \, dm \quad \text{for all } \phi \in C_c^\infty(M).
\]

Then we define the distributional \emph{Laplacian} of \( u \in H^1_{\text{loc}}(M) \) by \( \Delta u := \text{div}_m(\nabla u) \) in the weak sense that

\[
\int_M \phi \Delta u \, dm := -\int_M D\phi(\nabla u) \, dm \quad \text{for all } \phi \in C_c^\infty(M).
\]

We remark that \( H^1_{\text{loc}}(M) \) is defined solely in terms of the differentiable structure of \( M \). As the Legendre transform is nonlinear, this Laplacian is a nonlinear operator unless \( F \) comes from a Riemannian metric.

The weighted Ricci curvature \( \text{Ric}_N \) works quite well with the nonlinear Laplacian. Among others, we recall the Laplacian comparison theorem ([OS1, Theorem 5.2]) in the special case of nonnegative curvature, as well as the Bochner-Weitzenböck formula ([OS3, Theorems 3.3, 3.6]).
Theorem 2.8 (Laplacian comparison theorem) Let \((M,F)\) be forward or backward complete, and assume that \(\text{Ric}_N \geq 0\) for some \(N \in [n, \infty)\). Then, for any \(z \in M\), the function \(u(x) = d(z,x)\) satisfies
\[
\Delta u(x) \leq \frac{N - 1}{d(z,x)}
\]
point-wise on \(M \setminus (\{z\} \cup \text{Cut}_z)\), and in the distributional sense on \(M \setminus \{z\}\).

We denote by \(\text{Cut}_z\) the cut locus of \(z\). The cut locus is the set of cut points \(x = \exp_z(v)\) such that \(\eta(t) = \exp_z(tv)\) is minimal on \([0,1]\) but not minimal on \([0,1+\varepsilon]\) for any \(\varepsilon > 0\).

Theorem 2.9 (Bochner-Weitzenböck formula) Given \(u \in H^2_{\text{loc}}(M) \cap C^1(M)\) with \(\Delta u \in H^1_{\text{loc}}(M)\), we have
\[
\Delta \nabla u \left( \frac{F(\nabla u)^2}{2} \right) - D(\Delta u)(\nabla u) = \text{Ric}_\infty(\nabla u) + \|\nabla^2 u\|^2_{\text{HS}(\nabla u)}
\]
as well as
\[
\Delta \nabla u \left( \frac{F(\nabla u)^2}{2} \right) - D(\Delta u)(\nabla u) \geq \text{Ric}_N(\nabla u) + \frac{(\Delta u)^2}{N}
\]
for \(N \in [n, \infty]\) point-wise on \(M \setminus \{x \in M \mid \nabla u(x) = 0\}\), and in the weak sense on \(M\). Here \(\Delta \nabla u := \text{div}_m \circ \nabla^g \nabla u\) is the linearized Laplacian associated with \(g_{\nabla u}\), and \(\|\cdot\|_{\text{HS}(\nabla u)}\) stands for the Hilbert-Schmidt norm with respect to \(g_{\nabla u}\).

To be precise, in the definition of \(\Delta \nabla u\), we replace \(\nabla u\) with a measurable, non-vanishing vector field \(V\) such that \(V(x) = \nabla u(x)\) if \(\nabla u(x) \neq 0\). We remark that \(\Delta \nabla u = \Delta u\) holds ([OS1, Lemma 2.4]).

2.4 Berwald spaces

We introduce an important and reasonable class of Finsler manifolds.

Definition 2.10 (Berwald spaces) We say that a Finsler manifold \((M,F)\) is of Berwald type (or a Berwald space) if \(\Gamma^i_{jk}\) is constant on \(T_xM \setminus 0\) for every \(x \in M\).

Clearly Riemannian manifolds and (smooth) Minkowski normed spaces are of Berwald type. Non-Riemannian, non-flat Berwald spaces can be easily constructed by taking various kinds of products of Berwald spaces (cf. [Descartes products in Sz1 §2]). Berwald spaces enjoy several fine properties (see [BCS Chapter 10]), we recall two of them for later use (cf. [BCS Proposition 10.1.1, Theorem 10.6.2]).

Proposition 2.11 (Isometry of tangent spaces, [G]) Let \((M,F)\) be a Finsler manifold of Berwald type. Then, for any \(C^1\)-curve \(\eta : [0,1] \rightarrow M\) with \(\dot{\eta} \neq 0\), the parallel transport along \(\eta\) is a linear isometry between \((T_{\eta(0)}M, F|_{T_{\eta(0)}M})\) and \((T_{\eta(1)}M, F|_{T_{\eta(1)}M})\).

We remark that, in Berwald spaces, the covariant derivative (2.6) is independent of the choice of a reference vector. Thus the parallel transport is unambiguously defined.
Theorem 2.12 (Szabó’s rigidity, [Sz1]) Let \((M, F)\) be a connected Berwald surface. Then the following dichotomy holds.

- If the flag curvature is identically 0, then \(F\) is locally Minkowskian everywhere.
- If the flag curvature is not identically 0, then \(F\) is Riemannian everywhere.

Szabó also classified higher dimensional non-Riemannian Berwald metrics by means of holonomy theory ([Sz1], [Sz2]), whereas such a classification is not really helpful to our purpose. We also remark that the Busemann-Hausdorff measure satisfies \(S \equiv 0\) for Berwald spaces (cf. [Sh1, §7.3]), though this fact will not be used.

3 Analysis of Busemann functions

Let \((M, F)\) be forward complete in this section. We begin the study of the splitting phenomenon with analyzing Busemann functions.

We call a geodesic \(\eta : [0, \infty) \to M\) a ray if it is globally minimizing and has the unit speed (for brevity), i.e., \(d(\eta(s), \eta(t)) = t - s\) for all \(s < t\). Given a ray \(\eta\), the associated Busemann function \(b_\eta : M \to \mathbb{R}\) is defined by

\[
b_\eta(x) := \lim_{t \to \infty} \{t - d(x, \eta(t))\}.
\]

This limit indeed exists because the triangle inequality ensures, for any \(s < t\),

\[
s - d(x, \eta(s)) \leq s - \{d(x, \eta(t)) - (t - s)\} = t - d(x, \eta(t)) \leq d(\eta(0), x).
\]

The triangle inequality also shows that \(b_\eta\) is 1-Lipschitz in the sense that

\[
b_\eta(y) - b_\eta(x) \leq d(x, y) \quad \text{for all } x, y \in M,
\]

and hence \(b_\eta\) is differentiable almost everywhere.

We say that another ray \(\sigma : [0, \infty) \to M\) is asymptotic to \(\eta\), denoted by \(\sigma \sim \eta\), if there are sequences \(\{t_i\}_{i \in \mathbb{N}} \subset [0, \infty)\) and \(\{r_i\}_{i \in \mathbb{N}}\) such that \(\lim_{i \to \infty} t_i = \infty\), \(\sigma_i : [0, d(\sigma(0), \eta(t_i))] \to M\) is a minimal geodesic from \(\sigma(0)\) to \(\eta(t_i)\), and that \(\lim_{t \to \infty} \sigma_i(t) = \sigma(t)\) for all \(t \geq 0\). The next lemma is concerned with the fundamental properties of Busemann functions (cf. [SST, Theorem 3.8.2]). We give proofs for completeness as our distance is nonsymmetric.

Lemma 3.1 Let \(\eta : [0, \infty) \to M\) be a ray.

(i) For any \(x \in M\), there exists a ray \(\sigma\) asymptotic to \(\eta\) such that \(\sigma(0) = x\).

(ii) For any ray \(\sigma \sim \eta\) and \(s \geq 0\), it holds \(b_\eta(\sigma(s)) = b_\eta(\sigma(0)) + s\).

(iii) If \(b_\eta\) is differentiable at \(x \in M\), then \(\sigma(s) = \exp_x(s \nabla b_\eta(x))\) is a unique ray asymptotic to \(\eta\) emanating from \(x\).
Proof. (i) As \((M,F)\) is forward complete, we can choose a unit speed minimal geodesic \(\sigma_i\) from \(x\) to \(\eta(i)\) for each \(i \in \mathbb{N}\). By extracting a subsequence denoted again by \(\{\sigma_i\}_{i \in \mathbb{N}}\), the initial tangent vector \(\dot{\sigma}_i(0)\) converges to some unit vector \(v \in U_xM\). Then the ray \(\sigma(s) := \exp_x(sv)\) is asymptotic to \(\eta\) by construction.

(ii) Take \(\{t_i\}_{i \in \mathbb{N}}\) and \(\{\sigma_i\}_{i \in \mathbb{N}}\) as in the definition of the asymptoticity. It holds that

\[ b_{\eta}(\sigma(s)) = \lim_{i \to \infty} \{ t_i - d(\sigma(s), \eta(t_i)) \} \]

by the definition of \(b_{\eta}\). We can replace \(\sigma(s)\) in the right hand side with \(\sigma_i(s)\) since

\[ |d(\sigma(s), \eta(t_i)) - d(\sigma_i(s), \eta(t_i))| \leq \max \{ d(\sigma(s), \sigma_i(s)), d(\sigma_i(s), \sigma(s)) \} \to 0 \]

as \(i \to \infty\). Hence we have, by the choice of \(\sigma_i\),

\[
\begin{align*}
 b_{\eta}(\sigma(s)) &= \lim_{i \to \infty} \{ t_i - d(\sigma_i(s), \eta(t_i)) \} = \lim_{i \to \infty} \{ t_i - d(\sigma_i(0), \eta(t_i)) + s \} \\
&= \lim_{i \to \infty} \{ t_i - d(\sigma(0), \eta(t_i)) + s \} = b_{\eta}(\sigma(0)) + s.
\end{align*}
\]

(iii) Recall from \((3.1)\) that \(b_{\eta}\) is 1-Lipschitz. Then we deduce from (ii) that any ray \(\sigma \sim \eta\) with \(\sigma(0) = x\) must satisfy \(\dot{\sigma}(0) = \nabla b_{\eta}(x)\). This completes the proof. \(\Box\)

The following is a key analytic property of Busemann functions. The proof is similar to \([KS, \text{Lemma } 5.6]\) (see also \([EH], [FLZ, \text{Lemma } 2.1]\)) thanks to the Laplacian comparison theorem (Theorem \((2.8)\)).

**Proposition 3.2** Assume that \(\text{Ric}_N \geq 0\) for some \(N \in [n, \infty]\), and that \(\Psi : UM \to \mathbb{R}\) as in Definition \((2.4)\) is bounded above if \(N = \infty\). Then \(b_{\eta}\) is subharmonic, namely \(\Delta b_{\eta} \geq 0\) holds in the distributional sense.

**Proof.** We first treat the case of \(N < \infty\). Fix an arbitrary bounded open set \(\Omega \subset M\) and a nonnegative test function \(\phi \in H^1_0(\Omega)\). Put \(r_i(x) := -d(x, \eta(i))\) for \(i \in \mathbb{N}\). Note that \(r_i\) is differentiable almost everywhere and \(\nabla r_i(x)\) coincides with the initial vector of the unique unit speed minimal geodesic from \(x\) to \(\eta(i)\). Thanks to Lemma \((3.1)\)(iii) (and the construction in (ii)), we find \(\lim_{i \to \infty} \nabla r_i(x) = \nabla b_{\eta}(x)\) for \(x\) at where \(b_{\eta}\) is differentiable. Thus we have, by the dominated convergence theorem,

\[
\lim_{i \to \infty} \int_{\Omega} D\phi(\nabla r_i) \, dm = \int_{\Omega} D\phi(\nabla b_{\eta}) \, dm.
\]

In order to apply Theorem \((2.8)\) we observe (recall Definition \((2.7)\))

\[
\nabla r_i = -\hat{\nabla} (-r_i) = -\hat{\nabla} \left[ \frac{\phi}{d(\eta(i), \cdot)} \right].
\]

Hence Theorem \((2.8)\) for \(\hat{\nabla} F\) yields

\[
\int_{\Omega} D\phi(\nabla b_{\eta}) \, dm = \lim_{i \to \infty} \int_{\Omega} \phi \hat{\Delta} (-r_i) \, dm \leq (N - 1) \lim_{i \to \infty} \int_{\Omega} \frac{\phi}{-r_i} \, dm = 0. \tag{3.2}
\]
As for $N = \infty$, we derive from the calculation with respect to the Riemannian structure $g_{\nabla r_i}$ that (cf. [FLZ (2.1)]), since $\nabla g_{\nabla (-r_i)} = g_{\nabla (-r_i)} = g_{\nabla r_i}$, and all integral curves of $\nabla r_i$ are geodesic (with respect to $F$),

$$\tilde{\Delta}(-r_i)(x) \leq \frac{n-1}{r_i(x)} + \frac{2\Psi(\hat{\sigma}_i(0))}{r_i(x)} + 2\int_0^{-r_i(x)} \Psi(\hat{\sigma}_i) \, ds$$

$$\leq \frac{1}{r_i(x)} \left\{ (n-1) - 2\Psi(\hat{\sigma}_i(0)) + 2\sup_{UM} \Psi \right\}$$

for $x \in M \setminus \left( \{ \eta(i) \} \cup \tilde{\text{Cut}}_{\eta(i)} \right)$, where $\sigma_i : [0, -r_i(x)] \to M$ is the unique minimal geodesic from $x$ to $\eta(i)$ (with respect to $F$). Therefore (3.2) is available with

$$N_\Omega = n + 2 \left( \sup_{UM} \Psi - \inf_{\tilde{U}_\Omega} \Psi \right)$$

in place of $N$, and $b_\eta$ is subharmonic.

\[ \square \]

4 A diffeomorphic splitting

From here on, let $(M, F)$ be both forward and backward complete, and assume that $\text{Ric}_N \geq 0$ for some $N \in [n, \infty]$ and $\Psi$ (defined in Definition 2.4) is bounded above if $N = \infty$. Suppose that $(M, F)$ admits a straight line, that is, a geodesic $\eta : \mathbb{R} \to M$ with $d(\eta(s), \eta(t)) = t - s$ for all $s < t$. Let us consider the two Busemann functions

$$b_\eta(x) := \lim_{t \to \infty} \{ t - d(\eta(t), x) \}, \quad b_{\bar{\eta}}(x) := \lim_{t \to \infty} \{ t - d(\eta(-t), x) \},$$

where $b_\eta$ is precisely the Busemann function for the ray $\bar{\eta}(t) := \eta(-t), t \in [0, \infty)$, with respect to $F$.

**Proposition 4.1** Let $\eta : \mathbb{R} \to M$ be a straight line. Then we have $b_\eta + b_{\bar{\eta}} \equiv 0$, and $b_\eta$ and $b_{\bar{\eta}}$ are harmonic with respect to $F$ and $\tilde{F}$, namely $\Delta b_\eta = \tilde{\Delta} b_{\bar{\eta}} \equiv 0$. In particular, $b_\eta$ and $b_{\bar{\eta}}$ are $C^\infty$ and $\Delta b_\eta = \tilde{\Delta} b_{\bar{\eta}} \equiv 0$ in fact holds in the point-wise sense.

**Proof.** We immediately observe from the triangle inequality that $b_\eta + b_{\bar{\eta}} \leq 0$. Proposition 3.2 implies $\Delta b_\eta \geq 0$ as well as $\tilde{\Delta} b_{\bar{\eta}} \geq 0$ (note that $\tilde{\Psi}(v) = \Psi(-v)$). Therefore

$$\Delta b_\eta \geq 0 \geq -\tilde{\Delta} b_{\bar{\eta}} = \Delta(-b_{\bar{\eta}}),$$

while $b_\eta \circ \eta \equiv -b_{\bar{\eta}} \circ \eta$. Hence the strong maximum principle (see [Da, Theorem 2-2], [GS, Lemma 5.4]) yields $b_\eta = -b_{\bar{\eta}}$ and $\Delta b_\eta = \tilde{\Delta} b_{\bar{\eta}} \equiv 0$.

As a harmonic function is a static solution to the heat equation, $b_\eta$ is $C^{1,\alpha}$ by [OS1, Theorem 4.9] (see also [GS, Theorem 1.1]). Furthermore, $\nabla b_\eta$ does not vanish since $F(\nabla b_\eta) \equiv 1$ by Lemma 3.1(ii), so that $b_\eta$ and $b_{\bar{\eta}}$ are eventually $C^\infty$ (see [OS1, Remark 4.10], [GS, Theorem 1.1]).

\[ \square \]
We say that a straight line $\sigma : \mathbb{R} \to M$ is bi-asymptotic to $\eta$ if $\sigma|_{[0,\infty)} \sim \eta|_{[0,\infty)}$ and if $\bar{\sigma}(s) := \sigma(-s)$ is asymptotic to $\bar{\eta}$ with respect to $\bar{F}$. Combining Proposition 4.1 with Lemma 3.1(ii), we observe the following.

**Lemma 4.2.** Let $\eta : \mathbb{R} \to M$ be a straight line. Then, for any $x \in M$, the geodesic $\sigma : \mathbb{R} \to M$ with $\sigma(0) = \nabla b_\eta(x)$ is a unique straight line bi-asymptotic to $\eta$ such that $\sigma(0) = x$.

Lemma 3.1(ii) implies not only $\nabla b_\eta \neq 0$ but also that every integral curve of $\nabla b_\eta$ is geodesic. Therefore $\text{Ric}_N(\nabla b_\eta) = \text{Ric}_N(\nabla b_\eta)$ and we can apply the Cheeger-Gromoll-Lichnerowicz splitting theorem ([CG1], [Li]) to the weighted Riemannian manifold $(M, g_{\nabla b_\eta}, m_{\nabla b_\eta})$.

**Proposition 4.3 (Isometric splitting of $(M, g_{\nabla b_\eta}, m_{\nabla b_\eta})$)** If $(M, F)$ contains a straight line $\eta : \mathbb{R} \to M$, then $(M, g_{\nabla b_\eta})$ splits isometrically as $M = M' \times \mathbb{R}$ with $M' = b_\eta^{-1}(0)$, and $\Psi \circ \sigma$ is constant on the line $\sigma(s) = (x, s) \in M' \times \mathbb{R}$ for each $x \in M'$.

**Proof.** We give a sketch of the proof for thoroughness, see [FLZ, Theorem 1.1], [WW, Theorem 6.1] for details. Applying the Bochner-Weitzenböck formula for $g_{\nabla b_\eta}$ to $b_\eta$, we deduce from $\Delta \nabla b_\eta = \Delta b_\eta \equiv 0$ that

$$
\text{Ric}_\infty(\nabla b_\eta) + \|\nabla^2 b_\eta\|_{HS}^2 = \Delta \left( \frac{\|\nabla b_\eta\|^2}{2} \right) - D(\Delta b_\eta)(\nabla b_\eta) = 0,
$$

(4.1)

where $\nabla$ and $\Delta$ are with respect to $g_{\nabla b_\eta}$ and $m$. Thus the hypothesis $\text{Ric}_\infty \geq \text{Ric}_N \geq 0$ shows $\nabla^2 b_\eta \equiv 0$, namely $\nabla b_\eta$ is a parallel (and hence Killing) vector field. Therefore the associated one-parameter family of transforms $\varphi_t : M \to M$, $t \in \mathbb{R}$, consists of isometries (with respect to $g_{\nabla b_\eta}$) and $M$ is isometric to $M' \times \mathbb{R}$ with $M' := b_\eta^{-1}(0)$.

In order to split the measure $m$, we observe from

$$
\|\nabla^2 b_\eta\|_{HS}^2 \geq \frac{(\Delta b_\eta + D(\Psi \circ \nabla b_\eta)(\nabla b_\eta))^2}{n}
$$

that $D(\Psi \circ \nabla b_\eta)(\nabla b_\eta) \equiv 0$ (see, for example, the calculation in the proof of [OS3, Theorem 3.3]).

The boundedness of $\Psi$ is in fact necessary for splitting both $g_{\nabla b_\eta}$ and $m$, see [WW, Examples 2.1, 2.2] for simple interesting examples. Recall that we used the boundedness only in Proposition 3.2.

**Corollary 4.4 (Diffeomorphic splitting of $(M, m)$)** Assume that $(M, F)$ includes a straight line. Then $(M, m)$ admits a diffeomorphic, measure-preserving splitting $(M, m) = (M' \times \mathbb{R}, m' \times \mathbb{L}^1)$, where $\mathbb{L}^1$ is the one-dimensional Lebesgue measure and $m' := m|_{M'}$.

To be precise, the map

$$(M' \times \mathbb{R}, m' \times \mathbb{L}^1) \ni (x, t) \mapsto \varphi_t(x) \in (M, m)$$

12
is diffeomorphic and measure-preserving. We abused the notation that $m' = m|_{M'}$ denotes the projection of $m$ to $M'$, namely $m'(U) := m(U \times [0, 1])$ for any Borel set $U \subset M'$. It is unclear if this splitting procedure can be iterated, because it seems difficult to determine the structures of $(M', F|_{TM'}, m')$ as well as $(M', g_{\nabla b_\eta}|_{TM'}, m')$ from the construction in Proposition 4.3 (for instance, we do not know if they have the nonnegative curvature).

Remark 4.5 Corollary 4.4 would be compared with the structure theorem for a (non-branching) metric measure space $(X, d, m)$ satisfying the measure contraction property $\text{MCP}(K, N)$ (see [Oh1], [St3, Section 5]) with $N \in (1, \infty)$ and $K > 0$, as $\text{CD}(K, N)$ implies $\text{MCP}(K, N)$. If $(X, d)$ attains the maximal diameter $\pi \sqrt{(N - 1)/K}$, then $(X, m)$ is represented as the spherical suspension of some topological measure space ([Oh2, Section 5]). It is unknown whether a splitting theorem similar to Corollary 4.4 holds for general metric measure spaces satisfying $\text{MCP}(0, N)$ or $\text{CD}(0, N)$.

Though the following theorem is essentially included in Proposition 4.3, we state it separately for future convenience.

Theorem 4.6 Suppose that $(M, F, m)$ is forward and backward complete and satisfies $\text{Ric}_N \geq 0$ for some $N \in [n, \infty]$, and that $\Psi$ is bounded above if $N = \infty$. If $(M, F)$ contains a straight line $\eta : \mathbb{R} \to M$, then we have $\nabla^2 b_\eta \equiv 0$.

Proof. Applying the Bochner-Weitzenböck formula (Theorem 2.9) to the harmonic function $b_\eta$, we obtain

\[
\text{Ric}_\infty(\nabla b_\eta) + \|\nabla^2 b_\eta\|_{HS(\nabla b_\eta)} = 0
\]

and hence $\text{Ric}_\infty \geq \text{Ric}_N \geq 0$ implies $\nabla^2 b_\eta \equiv 0$. (We remark that this formula in fact coincides with the Bochner-Weitzenböck formula (4.1) for $g_{\nabla b_\eta}$ due to the fact that all integral curves of $\nabla b_\eta$ are geodesic, see [OS3, Remark 3.4]. Thus we do not really need the formula in the Riemannian case is enough.)

One may be able to derive from $\nabla^2 b_\eta \equiv 0$ some more information on the structure of $(M, F)$, whereas we have succeeded only in the Berwald case (discussed in the next section).

5 Berwald case

In this final section, we investigate a more detailed splitting phenomenon of Berwald spaces (recall Definition 2.10). Throughout the section, let $(M, F, m)$ be a forward and backward complete Berwald space, and assume that $\text{Ric}_N \geq 0$ for some $N \in [n, \infty]$ and $\Psi$ is bounded above if $N = \infty$. By the definition of Berwald spaces, the covariant derivative (2.6) does not depend on the choice of a reference vector, so that we will omit reference vectors in this section. In particular, the covariant derivative is linear in the sense that $D_v(W + X) = D_vW + D_vX$.

A subset $A \subset M$ is said to be totally convex if any minimal geodesic joining two points in $A$ is contained in $A$. We say that $A \subset M$ is geodesically complete if, for any geodesic $\eta : (0, \varepsilon) \to M$ contained in $A$, its extension $\eta : \mathbb{R} \to M$ as a geodesic is still contained in $A$. 

13
Lemma 5.1 Suppose that $(M, F)$ contains a straight line $\eta : \mathbb{R} \to M$. Then, given any geodesic $\xi : [0, l] \to M$, we have $(b_\eta \circ \xi)'' \equiv 0$. In particular, for each $t \in \mathbb{R}$, $b_\eta^{-1}(t)$ is totally convex and geodesically complete.

Proof. We observe

$$(b_\eta \circ \xi)'' = g\nabla_{b_\eta}(D_\xi(\nabla b_\eta), \dot{\xi}) + g\nabla_{b_\eta}(\nabla b_\eta, D_\xi \dot{\xi}) = 0$$

(see [BCS] Exercises 10.1.1, 10.1.2 for the first equality). To be precise, the first term vanishes in general by Theorem 4.6 while the second term vanishes only in Berwald spaces (since the covariant derivatives have $\nabla b_\eta$ as the reference vector). We in particular find that $b_\eta \circ \xi$ is constant if $b_\eta(\xi(r)) = b_\eta(\xi(s))$ for some $r \neq s$, so that $b_\eta^{-1}(t)$ is totally convex and geodesically complete.

Define $\varphi_t : M \to M$, $t \in \mathbb{R}$, as the one-parameter family of $C^\infty$-transforms generated from $\nabla b_\eta$. Precisely, $\partial \varphi_t/\partial t = \nabla b_\eta(\varphi_t)$.

Proposition 5.2 Suppose that $(M,F)$ contains a straight line $\eta : \mathbb{R} \to M$. Then we have the following.

(i) For any $t \in \mathbb{R}$, $\varphi_t$ is a measure-preserving isometry such that $\varphi_t(M_0) = M_t$, where we set $M_t := b_\eta^{-1}(t)$. Moreover, it holds $M = \bigsqcup_{t \in \mathbb{R}} \varphi_t(M_0)$.

(ii) The $(n-1)$-dimensional submanifold $(M_0, F|_{TM_0}, m_0)$ is again of Berwald type and satisfies $\text{Ric}_{N-1} \geq 0$, where $m_0 := m|_{M_0}$ (as in Corollary 4.4).

(iii) Define the projection $\rho : M \to M_0$ by $\rho(\varphi_t(x)) := x$ for $(x, t) \in M_0 \times \mathbb{R}$. Then a curve $\xi : \mathbb{R} \to M$ is geodesic if and only if the projections $\rho(\xi) : \mathbb{R} \to M_0$ and $b_\eta(\xi) : \mathbb{R} \to \mathbb{R}$ are geodesic.

Proof. (i) We have already seen in Corollary 4.4 that $\varphi_t$ is measure-preserving. Given any $v \in T_x M$, the isometric splitting of $(M, g\nabla b_\eta, m)$ (Proposition 4.3) shows that $V(t) := D\varphi_t(v)$ is a parallel vector field with respect to $g\nabla b_\eta$ along the geodesic $\sigma(t) = \varphi_t(x)$. Hence it follows from Lemma 2.3 that $D_\sigma V = D_\sigma^2 V = D_\sigma g\nabla b_\eta V \equiv 0$. Thus we obtain

$$\frac{\partial}{\partial t} [F(V)^2] = \frac{\partial}{\partial t} [g_V(V, V)] = 2g_V(D_\sigma V, V) \equiv 0$$

and $\varphi_t$ is isometric (we were again indebted to the fine property $D_\sigma^2 V = D_\sigma^2 V$ of Berwald spaces).

(ii) The total convexity in Lemma 5.1 guarantees that $(M_0, F|_{TM_0})$ is of Berwald type (via the characterization (e) in [BCS] Theorem 10.2.1 for instance). In order to see $\text{Ric}_{N-1} \geq 0$, recall from Corollary 4.4 that $m_0$ enjoys $m = m_0 \times L^1$. Fix a unit vector $v \in U_p M_0$ and extend it to a vector field $V_0$ on a neighborhood $U \subset M_0$ of $x$ such that all integral curves of $V_0$ are geodesic. We further extend $V_0$ to $V$ on $U \times (-\varepsilon, \varepsilon) \subset M$ by $V(y, t) = (V_0(y), 0) \in T_{(y,t)} M$. Then all integral curves of $V$ are geodesic and we deduce

$$\text{Ric}_{N-1} M_0(v) = \text{Ric}_M^M ((v, 0)) \geq 0$$
from (iii) below (as in Corollary 5.3(ii)) and the definition of \( \text{Ric}_N \) (since \((N-1)-(n-1) = N-n\)).

(iii) We can split the geodesic equation (2.7) for \( M \) into those for \( M_0 \) and \( \mathbb{R} \) by virtue of a special property of Berwald spaces. Take an open set \( U \subset M_0 \) and a coordinate \((x^1, x^2, \ldots, x^n)\) of \( U \times \mathbb{R} \subset M \) such that \( b_y(x) = x^n \) and that \((\partial/\partial x^i)_{i=1}^n\) is orthonormal with respect to \( g_{b_y} \). As \( \Gamma^i_{jk} \) is constant on every tangent space \( T_xM \setminus 0 \), let us denote it by \( \Gamma^i_{jk}(x) \). We shall calculate

\[
\Gamma^i_{jk}(x) = \Gamma^i_{jk}((\nabla b_y(x)) = \gamma^i_{jk}((\nabla b_y(x)) - \sum_{m=1}^{n} (A_{jin}N_{k}^{m} + A_{ikm}N_{j}^{m} - A_{jkm}N_{i}^{m})((\nabla b_y(x)).
\]

Note that

\[
\frac{\partial g_{ij}}{\partial x^n}((\nabla b_y) = 0 \quad \text{for} \quad i, j = 1, 2, \ldots, n
\]

by (i), and that

\[
\frac{\partial g_{im}}{\partial x^n}((\nabla b_y) = 0 \quad \text{for} \quad i, j = 1, 2, \ldots, n
\]

by \( g_{b_y}(\nabla b_y, TM_0) = 0 \) (if \( i \neq n) \) and \( F((\nabla b_y) = 1 \) (if \( i = n). \) Hence \( \gamma^i_{jk}((\nabla b_y(x)) = 0 \) unless \( i, j, k \neq n \). In particular, it follows from (2.4) that \( N_{j}((\nabla b_y(x)) = 0 \) for all \( i, j = 1, 2, \ldots, n \). Therefore we have \( \Gamma^i_{jk}(x) = 0 \) unless \( i, j, k \neq n \), so that

\[
D_{\xi}\dot{\xi} = \sum_{i=1}^{n-1} \left\{ \ddot{\xi}^i + \sum_{j,k=1}^{n-1} \Gamma^i_{jk}(\xi)\ddot{\xi}^j\dot{\xi}^k \right\} \frac{\partial}{\partial x^i} + \ddot{\xi}^n \frac{\partial}{\partial x^n}.
\]

Thus the geodesic equation is split and we complete the proof. \( \square \)

We remark that, different from the Riemannian case, one can not reconstruct \((M, F)\) only from \((M_0, F|_{TM_0})\). Indeed, given \( x \in M_0 \), all we know is \( F|_{T_xM_0} \) and the fact that \( T_xM_0 \perp \nabla b_y(x) \) with respect to \( g_{b_y} \). They give us only a little information about \( F|_{T_xM_0} \) (see the related discussion in Remark 5.5 below).

We can iterate the procedure in Proposition 5.2 and obtain the following.

**Corollary 5.3** (i) There exists a \( k \)-parameter family of measure-preserving isometries \( \varphi_p: M \rightarrow M, \quad p \in \mathbb{R}^k \), and an \((n-k)\)-dimensional totally convex, geodesically complete submanifold \( M' \subset M \) such that

- \((M', F|_{TM'})\) does not contain a straight line;
- \((M', F|_{TM'}, m')\) is of Berwald type with \( \text{Ric}_{N-k} \geq 0 \), where \( m' := m|_{M'} \);
- \( \bigcup_{p \in \mathbb{R}^k} \varphi_p(M') = M; \)
- \( \varphi_{p+q} = \varphi_q \circ \varphi_p \) for any \( p, q \in \mathbb{R}^k \).

In particular, \((M, m)\) admits a diffeomorphic, measure-preserving splitting \((M, m) = (M' \times \mathbb{R}^k, m' \times L^k)\).
(ii) For each $x \in M$, $\Sigma_x := \{\varphi_p(x)\}_{p \in R^k}$ is a $k$-dimensional submanifold of $M$ whose flag curvature (with respect to the restriction of $F$) vanishes everywhere.

(iii) For any $x, y \in M'$, $(\Sigma_x, F|_{T\Sigma_x})$ is isometric to $(\Sigma_y, F|_{T\Sigma_y})$.

**Proof.** (i) There is nothing to prove if $(M, F)$ does not contain a straight line ($k = 0, M' = M$). If $(M, F)$ contains a straight line $\eta_1 : \mathbb{R} \to M$, then Proposition 5.2 provides a one-parameter family $\{\varphi_t^{(1)}\}_{t \in \mathbb{R}}$ of measure-preserving isometries and an $(n-1)$-dimensional totally convex, geodesically complete submanifold $M_1 \subset M$ of $\text{Ric}_{N-1} \geq 0$. Suppose that $M_1$ contains a straight line $\eta_2 : \mathbb{R} \to M_1$ again. We remark that $\eta_2$ is a straight line also as a curve in $M$ thanks to Proposition 5.2 (iii). Similarly to $\varphi_t^{(1)}$, we obtain $\varphi_s^{(2)} : M_1 \to M_1$, $s \in \mathbb{R}$, and $M_2 \subset M_1$. Now, define $\varphi_{(t,s)} : M = M_1 \times \mathbb{R} \to M$ by

$$\varphi_{(t,s)}(x, r) := \varphi_t^{(1)}(\varphi_s^{(2)}(x), r) = (\varphi_s^{(2)}(x), r + t).$$

This map clearly preserves the measure $m$. To see that $\varphi_{(t,s)}$ is isometric, it is sufficient to show that the map $(x, r) \mapsto (\varphi_s^{(2)}(x), r)$ is isometric. Consider the vector field $V := (\nabla b_{m_1}, 0) \in TM_1 \times T\mathbb{R} = TM$. Note that all integral curves of $V$ are straight lines and mutually bi-asymptotic (compare two lines $\xi, \zeta \subset M_1$ and then $\xi$ and $\varphi_t \circ \xi$). Therefore $V$ coincides with the gradient vector field of the Busemann function on $M$ for the line $\eta_2$ (see Lemma 4.2). Hence the argument as in Proposition 5.2 (i) ensures that $\varphi_{(t,s)}$ is isometric.

The relation $\varphi_{(t+s',t+s')} = \varphi_{(t,s)} \circ \varphi_{(t',s')}$ is straightforward from the construction. Iterating this procedure as far as possible provides the desired space $M'$ containing no straight line as well as the family of isometries $\{\varphi_p\}_{p \in R^k}$.

(ii) The flatness is a consequence of the rigidity theorem for Berwald surfaces (Theorem 2.12). As $\Sigma_x$ is totally geodesic (in other words, locally totally convex) by Proposition 5.2 (iii), it is of Berwald type and we can apply Theorem 2.12 to each two-dimensional subspace $\Pi$ of $\Sigma_x$ (precisely, $\Pi = \{\varphi_p(x)\}_{p \in P}$ for a two-dimensional affine subspace $P \subset R^k$). Proposition 5.2 (iii) also verifies that $\Pi$ must be flat even if it is Riemannian, therefore $\Sigma_x$ is flat.

(iii) Take a minimal geodesic $\xi : [0, 1] \to M'$ from $x$ to $y$ and $p \in R^k$. By Theorem 4.6 the parallel transport along $\varphi_p \circ \xi$ sends $\nabla b_{m_1}(\varphi_p(x))$ to $\nabla b_{m_1}(\varphi_p(y))$ for any $i = 1, \ldots, k$. Since parallel transports are linearly isometric in Berwald spaces (Proposition 2.11) and $T_{\varphi_p(x)} \Sigma_x = \text{span}\{\nabla b_{m_1}(\varphi_p(x)) | i = 1, \ldots, k\}$, we conclude that $\Sigma_x$ is isometric to $\Sigma_y$. □

We remark that flat Berwald spaces are necessarily locally Minkowskian ([BCS, Proposition 10.5.1]). Hence, if $M'$ degenerates to a single point $\{x\}$ ($k = n$), then $M = \Sigma_x$ is an $n$-dimensional Minkowski normed space. In general, however, it is unclear from the infinitesimal discussion in Proposition 5.2 and Corollary 5.3 if $\Sigma_x$ is globally totally convex in $M$ (see also Remark 5.5 below). One may be able to split $M'$ again in a slightly different way as follows.

**Theorem 5.4 (Isometric splitting of Berwald spaces)** Suppose that $(M, F, m)$ is of Berwald type and forward and backward complete, and satisfies $\text{Ric}_N \geq 0$ for some $N \in [n, \infty]$. Assume also that $\Psi$ is bounded above if $N = \infty$. Then the following hold.
(i) There exists an $l$-parameter family of measure-preserving isometries $\varphi_p : M \rightarrow M$, $p \in \mathbb{R}^l$, and an $(n-l)$-dimensional totally convex, geodesically complete submanifold $\overline{M} \subset M$ such that

- any Busemann function associated with a straight line in $M$ is constant on $\overline{M}$;
- $(\overline{M}, F|_{\overline{M}}, \overline{m})$ is of Berwald type with $\text{Ric}_{\overline{M}} \geq 0$, where $\overline{m} := m|_{\overline{M}}$;
- $\bigcup_{p \in \mathbb{R}^l} \varphi_p(\overline{M}) = M$;
- $\varphi_{p+q} = \varphi_q \circ \varphi_p$ for any $p, q \in \mathbb{R}^l$.

In particular, $(M, m)$ admits a diffeomorphic, measure-preserving splitting $(M, m) = (\overline{M} \times \mathbb{R}^l, \overline{m} \times \mathbf{L}^l)$.

(ii) For each $x \in M$, $\Sigma_x := \{\varphi_p(x)\}_{p \in \mathbb{R}^l}$ is an $l$-dimensional submanifold of $M$ whose flag curvature vanishes everywhere.

(iii) For any $x, y \in \overline{M}$, $(\Sigma_x, F|_{\Sigma_x})$ is isometric to $(\Sigma_y, F|_{\Sigma_y})$.

Proof. (i) We start from the splitting $(M, m) = (M' \times \mathbb{R}^k, m' \times \mathbf{L}^k)$ in Corollary 5.3 and shall use the same notations. Assume that there is a straight line $\eta : \mathbb{R} \rightarrow M$ such that the geodesic equation of $\eta$ is a totally convex, geodesically complete, $(n-k-1)$-dimensional submanifold of Berwald type. We next split $M'$. In the canonical coordinate $(x, r_1, \ldots, r_k)$ of $M' \times \mathbb{R}^k$, $\dot{\eta}(0) \in T_0 M$ is written as $(v, a_1, \ldots, a_k)$ with nonzero $v$. As $\nabla b_\eta$ is a parallel vector field (and so are $\nabla b_\eta', \ldots, \nabla b_\eta^k$), the $T\mathbb{R}^k$-component of $\nabla b_\eta$ is always $(a_1, \ldots, a_k)$. Observe that the $TM'$-component of $\nabla b_\eta$ is a parallel vector field as well due to the linearity of the covariant derivative. Hence, for any $p \in \mathbb{R}^k$ and $x \in M'$, $\nabla b_\eta(x)$ and $\nabla b_\eta(\varphi_p(x))$ have the same $T_x M'$-components. Therefore the one-parameter family of measure-preserving isometries $\psi_t : M \rightarrow M$, $t \in \mathbb{R}$, generated from $\nabla b_\eta$ splits into

$$\psi_t = (\psi_t^{(1)}, \psi_t^{(2)}) \quad \text{with} \quad \psi_t^{(1)} : M' \rightarrow M', \quad \psi_t^{(2)} : \mathbb{R}^k \rightarrow \mathbb{R}^k,$$

and is written in the above coordinate as

$$\psi_t(x, r_1, \ldots, r_k) = (\psi_t^{(1)}(x), r_1 + ta_1, \ldots, r_k + ta_k).$$

Thus $\psi_t^{(1)} = [(\text{Id}_{M'}, \psi_t^{(2)}_v) \circ \psi_t]|_{M'}$ derives a diffeomorphic, measure-preserving splitting $(M', m') = (M'' \times \mathbb{R}, m'|_{M''} \times \mathbf{L}^l)$.

We remark that the geodesic equation of $M'$ splits into those of $M'' \times \eta(\mathbb{R})$ and then of $M'' \times \mathbb{R}$ (via the projection of $\eta(\mathbb{R})$ to $M'$ in the splitting $M' \times \mathbb{R}^k$). Then we see that $(M'', F, m'|_{M''})$ satisfies $\text{Ric}_{M''} \geq 0$ similarly to Proposition 5.2(ii). Iterating this construction as far as possible, we eventually obtain the desired submanifold $\overline{M}$.

(ii) and (iii) are shown in the same way as Corollary 5.3(ii), (iii). \hfill \Box

Due to (i) above, starting from a point $x \in M$, we can characterize $\overline{M} \ni x$ by $\overline{M} = \bigcap_\eta b_\eta^{-1}(0)$, where $\eta$ runs over all straight lines parametrized as $b_\eta(x) = 0$.  

17
Remark 5.5 Obviously $k \leq l$ holds for $k$ in Corollary 5.3 and $l$ in Theorem 5.4. The author does not know any example satisfying $k < l$. We can verify $k = l$ if, for $\eta$ in the proof of Theorem 5.4(i), the projection $\rho(\eta) : \mathbb{R} \to M'$ is a straight line (note the difference between $\eta_2 \subset M_l$ in Corollary 5.3(i) and $\eta \not\subset M'$ in Theorem 5.4(i)). The difficulty comes from the fact that a (Minkowski) normed space $(\mathbb{R}^n, |\cdot|)$ may contain a triple $v, w_1, w_2 \in \mathbb{R}^n \setminus \{0\}$ such that

$$g_\nu(v, w_1) = g_\nu(v, w_2) = 0, \quad |w_1| < |w_2|, \quad |w_1 + v| > |w_2 + v|.$$

Having Theorem 5.4 at hand, we can obtain some topological information of compact Berwald spaces along the lines of Cheeger and Gromoll’s classical theory ([CG1], [CG2]).

Theorem 5.6 (A Betti number estimate) Let $(M, F, m)$ be a compact Finsler manifold of Berwald type satisfying $\text{Ric}_N \geq 0$ for some $N \in [n, \infty]$. Denote by $(\widetilde{M}, \widetilde{F})$ the universal Finsler covering of $(M, F)$ and by $\widetilde{M} = \overline{M} \times \mathbb{R}^l$ its splitting obtained in Theorem 5.4. Then we have the following.

(i) $\overline{M}$ is compact.

(ii) There exists a finite normal subgroup $\Xi$ of the fundamental group $\pi_1(M)$ such that $\pi_1(M)/\Xi$ contains $\mathbb{Z}^l$ as a normal subgroup of finite index.

(iii) The first Betti number of $M$ is at most $l$.

Proof. Let us first give a remark on the action of the isometry group $\text{Isom}(\overline{M}, \widetilde{F})$. For each $\Phi \in \text{Isom}(\overline{M}, \widetilde{F})$ and any straight line $\eta : \mathbb{R} \to \overline{M}$, it clearly holds $b_{\Phi \circ \eta} \circ \Phi = b_\eta$. Hence $\Phi(\overline{M})$ inherits the property that all Busemann functions are constant.

(i) Let $\Gamma \subset \text{Isom}(\overline{M}, \widetilde{F})$ be the deck transformation group of the universal covering $\pi : \overline{M} \to M$. Since $\overline{M}$ is compact, we can take a compact fundamental domain $K \subset \overline{M}$ such that $\Gamma(K) = \overline{M}$. Now, if $\overline{M}$ is not compact, then there is a ray $\eta : [0, \infty) \to \overline{M}$ contained in $\overline{M}$. For each $i \in \mathbb{N}$, we can choose $\Phi(i) \in \Gamma$ satisfying $\Phi(i)(\eta(i)) \in K$. Then $\eta_t(\Phi(i)) := \Phi(i)(\eta(i + t)), t \in [-i, \infty)$, is a globally minimizing geodesic with $\eta_t(0) \in K$, and the compactness of $K$ ensures that $\{\eta_i\}_{i \in \mathbb{N}}$ has a subsequence convergent to some geodesic $\eta_\infty : \mathbb{R} \to M$ ($\eta_0(0) \to \eta_\infty(0)$ to be precise). This geodesic $\eta_\infty$ is a straight line by construction, and the Busemann function $b_{\eta_\infty}$ is not constant on $\Phi(\overline{M})$ for large $i$ (since $\eta_i / T(\Phi(\overline{M}))$. This is a contradiction, so that $\overline{M}$ is compact.

(ii) Fix $\Phi \in \text{Isom}(\overline{M}, \widetilde{F})$. On the one hand, for each $p \in \mathbb{R}^l$, $\Phi(\varphi_p(\overline{M}))$ coincides with $\varphi_p(\overline{M})$ for some $q \in \mathbb{R}^l$ from the construction of $\overline{M}$ (since $\Phi$ preserves Busemann functions). On the other hand, for each $x \in \overline{M}$, we find that $\Phi(\Sigma_x) = \Sigma_y$ for some $y \in \overline{M}$ by the same reasoning. Then the projection

$$\Phi_1 := \varphi_{p-q} \circ \Phi|_{\varphi_p(\overline{M})} \in \text{Isom}(\varphi_p(\overline{M}), \widetilde{F}) = \text{Isom}(\overline{M}, \widetilde{F})$$

(we identified $\text{Isom}(\varphi_p(\overline{M}), \widetilde{F})$ with $\text{Isom}(\overline{M}, \widetilde{F})$ via $\varphi_p$) is independent of the choice of $p \in \mathbb{R}^l$ because $\Phi$ preserves the $\mathbb{R}^l$-directions (that is, $\Phi(\Sigma_x) = \Sigma_y$ and $\Phi_1(x) = y$).
We similarly see that $\Phi_2 := \Phi|_{\Sigma_x} \in \text{Isom}(\Sigma_x, \tilde{F})$ is independent of the choice of $x \in \tilde{M}$ by identifying $\Sigma_x$ and $\Sigma_y$ via the coordinate of $\mathbb{R}^l$ ($\Phi_2(p) = q$, $\Sigma_x$ and $\Sigma_y$ are actually isometric by Theorem 5.4(iii)). Consequently, we obtain

$$\text{Isom}(\tilde{M}, \tilde{F}) = \text{Isom}(\tilde{M}, \tilde{F}) \times \text{Isom}(\Sigma_x, \tilde{F}).$$

Since $\text{Isom}(\tilde{M}, \tilde{F})$ is compact, $\Xi := \{ \Phi \in \Gamma \mid \Phi_2 = \text{Id}_{\Sigma_x} \}$ is a finite normal subgroup of $\Gamma = \pi_1(M)$. The covering

$$\tilde{M} = \overline{M} \times \mathbb{R}^l \rightarrow \tilde{M}/\Xi =: \overline{M} \times \mathbb{R}^l$$

leads

$$\text{Isom}(\tilde{M}/\Xi, \tilde{F}) = \text{Isom}(\overline{M}, \tilde{F}) \times \text{Isom}(\Sigma_x, \tilde{F}) \supset \Gamma/\Xi,$$

and the projection of $\Gamma/\Xi$ to $\text{Isom}(\Sigma_x, \tilde{F})$ is an isomorphism into its image. As $\Sigma_x$ is flat (Theorem 5.4(ii)), $\text{Isom}(\Sigma_x, \tilde{F})$ is a subgroup of the isometry group $\text{Isom}(\mathbb{R}^l)$ of $\mathbb{R}^l$ with the standard Euclidean metric. Thus $\Gamma/\Xi$ is isomorphic to a discrete uniform subgroup of $\text{Isom}(\mathbb{R}^l)$. Therefore $\Gamma/\Xi$ is isomorphic to a crystallographic group of $\mathbb{R}^l$, and contains $\mathbb{Z}^l$ as a normal subgroup of finite index by the Bieberbach theorem.

(iii) This is a consequence of (ii). \hfill \Box

Recall that, if $l = n$, then $\tilde{M}$ is a Minkowski normed space. Our argument was indebted to various fine properties of Berwald spaces, even at the early stage (see Lemma 5.1, Proposition 5.2). It is unclear if any of results in this section can be generalized to general Finsler manifolds.
